OPENSTAX

OpenStax provides free, peer-reviewed, openly licensed textbooks for introductory college and Advanced Placement® courses and low-cost, personalized courseware that helps students learn. A nonprofit ed tech initiative based at Rice University, we're committed to helping students access the tools they need to complete their courses and meet their educational goals.

RICE UNIVERSITY

OpenStax is an initiative of Rice University. As a leading research university with a distinctive commitment to undergraduate education, Rice University aspires to path-breaking research, unsurpassed teaching, and contributions to the betterment of our world. It seeks to fulfill this mission by cultivating a diverse community of learning and discovery that produces leaders across the spectrum of human endeavor.

PHILANTHROPIC SUPPORT

OpenStax is grateful for the generous philanthropic partners who advance our mission to improve educational access and learning for everyone. To see the impact of our supporter community and our most updated list of partners, please visit openstax.org/foundation.

The screenshot shows a digital book interface on a tablet. At the top, it says 'College Success' and '2.2 The Motivated Learner'. On the left is a table of contents for Chapter 2.2, which includes sections like 'Preface', 'Exploring College', 'Knowing Yourself as a Learner', 'The Power to Learn', 'The Motivated Learner', 'It's All in the Mindset', 'Learning Styles', 'Personality Types and Learning', 'Applying What You Know about Learning', 'The Hidden Curriculum', 'Summary', 'Career Connection', 'Reflecting', 'Where do you go from here?', 'Managing Your Time and Priorities', 'Planning Your Academic Pathways', 'Reading and Note-taking', 'Studying, Memory, and Test Taking', 'Thinking', 'Communicating', 'Understanding Civility and Cultural Competence', and 'Understanding Financial Literacy'. The main content area is titled 'Resilience and Grit'. It contains text about grit and resilience, a photograph of two athletes running on a track, and a callout box with a 'RESILIENCE' input field and 'Save' and 'Cancel' buttons. At the bottom, there is a note about research showing that grit and perseverance are better predictors of academic success than talent or IQ.

Access. The future of education.

UNIT 1 PRESERVING THE HEALTH OF POPULATIONS AND COMMUNITIES

CHAPTER 1

What Is Population Health? 9

Introduction	9
1.1 Defining Population Health	10
1.2 Why Population Health Is Important	18
1.3 Population-Based Practice in Nursing	22
Chapter Summary	28
Key Terms	28
Review Questions	29

CHAPTER 2

Foundations of Public/Community Health 31

Introduction	31
2.1 Defining Public Health	32
2.2 Historical Perspectives on Public/Community Health	37
2.3 The Importance of Public/Community Health	41
2.4 The Core Functions and Essential Services of Public Health	44
2.5 Levels of Prevention	48
Chapter Summary	51
Key Terms	51
Review Questions	52

CHAPTER 3

Public/Community Health in Practice 55

Introduction	55
3.1 Defining Public/Community Health Nursing	56
3.2 Public/Community Health Nursing Scope of Practice, Core Competencies, and Function	62
3.3 Public/Community Health Nursing Practice	68
Chapter Summary	80
Key Terms	80
Review Questions	80

CHAPTER 4

The Health of the Population 83

Introduction	83
4.1 Defining Health	84
4.2 Performance Metrics	86
4.3 Health in America	90

4.4 World Health Statistics	98
4.5 Global Public Health Security	104
Chapter Summary	107
Key Terms	107
Review Questions	108

UNIT 2 ISSUES AND CHALLENGES OF POPULATION HEALTH

CHAPTER 5

Demographic Trends and Societal Changes 111

Introduction	111
5.1 Demographic Factors	111
5.2 Health Care Consumer Behavior	118
5.3 Virtual Care and Technology	121
5.4 Health Care Workforce	125
Chapter Summary	128
Key Terms	128
Review Questions	129

CHAPTER 6

Structural Racism and Systemic Inequities 131

Introduction	131
6.1 Understanding Different Forms of Racism	132
6.2 The Historical Context of Structural Racism in the United States	135
6.3 Contemporary Structural Racism and Systemic Inequities in the United States	144
6.4 Structural Racism and Systemic Inequities in U.S. Health Care	149
Chapter Summary	160
Key Terms	160
Review Questions	161

CHAPTER 7

Policies and Regulatory Conditions Impacting Health Outcomes

163

Introduction	163
7.1 Factors Affecting Public Health Policy	164
7.2 Balancing Individual Rights and Public Health Interests	170
7.3 Public Health Initiatives, Delivery Mechanisms, and Implications	175
7.4 Policies Affecting Drug Approval, Supply, and Cost	179
Chapter Summary	184
Key Terms	184
Review Questions	185

CHAPTER 8

Social Determinants Affecting Health Outcomes 189

Introduction	189
8.1 Economic Stability	191
8.2 Neighborhood and Built Environment	196

8.3 Educational Environment, Access, and Quality	204
8.4 Social and Community Context	208
8.5 The Cumulative Effect of Inequalities on Health	212
Chapter Summary	214
Key Terms	214
Review Questions	215

CHAPTER 9 **Health Disparities** 217

Introduction	217
9.1 Health Disparities Defined	218
9.2 Race and Ethnicity Disparities	224
9.3 Gender Disparities	227
9.4 Geographical Disparities	230
Chapter Summary	234
Key Terms	234
Review Questions	234

UNIT 3 POPULATION-BASED PRACTICE AND THE TENETS OF PUBLIC HEALTH

CHAPTER 10 **Socio-Ecological Perspectives and Health** 237

Introduction	237
10.1 Factors That Influence Health Practices	238
10.2 Theories and Models of Health Behavior	244
10.3 Core Principles of the Socio-Ecological Model	250
Chapter Summary	257
Key Terms	257
Review Questions	257

CHAPTER 11 **Evidence-Based Decision-Making** 261

Introduction	261
11.1 What Is Evidence-Based Decision-Making?	262
11.2 Where to Find Evidence-Based Interventions	270
11.3 Evaluating the Quality of the Evidence	275
Chapter Summary	280
Key Terms	280
Review Questions	281

CHAPTER 12 **Epidemiology for Informing Population/Community Health Decisions** 283

Introduction	283
12.1 Epidemiology Defined	284
12.2 Historical Perspective	285
12.3 Epidemiological Approaches	287

12.4 Types of Study Design	292
12.5 Epidemiologic Measures	295
12.6 Communicating Inferences from Epidemiologic Data	305
12.7 The Role of Epidemiology in Scientific Decision-Making and Policy Development	307
Chapter Summary	312
Key Terms	313
Review Questions	314

CHAPTER 13

Pandemics and Infectious Disease Outbreaks 317

Introduction	317
13.1 Pandemics Throughout History	318
13.2 Types of Infectious Disease Outbreaks	322
13.3 Infectious Disease Prevention and Control	349
Chapter Summary	355
Key Terms	355
Review Questions	356

CHAPTER 14

Environmental Health 359

Introduction	359
14.1 Understanding Environmental Health	360
14.2 Environmental Exposure and Health Outcomes	366
14.3 Environmental Health Assessment	371
14.4 Climate Change and Population Health	377
14.5 Nursing Practice and Responsibilities in Environmental Health	385
Chapter Summary	389
Key Terms	389
Review Questions	391

CHAPTER 15

Health Promotion and Disease Prevention Strategies 393

Introduction	393
15.1 Defining Health Promotion and Disease Prevention	394
15.2 Health Promotion and Disease Prevention Interventions	398
15.3 Theories and Models	404
15.4 Barriers and Opportunities for Health Promotion and Disease Prevention	408
Chapter Summary	415
Key Terms	415

UNIT 4 MERGING PUBLIC HEALTH PRINCIPLES WITH THE NURSING PROCESS

CHAPTER 16

Creating a Healthy Community 419

Introduction	419
16.1 The Community as the Client	420

16.2 What Is a Healthy Community?	427
16.3 The Nursing Process as a Framework	431
Chapter Summary	434
Key Terms	434
Review Questions	434

CHAPTER 17

Assessment, Analysis, and Diagnosis 437

Introduction	437
17.1 Assessment Tools and Application to Practice	438
17.2 Assessment of Individual and Community Needs for Health Education	452
17.3 Analyzing Population Health Data and Identifying Patterns	458
17.4 Formulating a Nursing Community Diagnosis and Plan of Care	459
Chapter Summary	463
Key Terms	463
Review Questions	464

CHAPTER 18

Planning Health Promotion and Disease Prevention Interventions 467

Introduction	467
18.1 Theories and Models to Guide Program Planning	468
18.2 Partnerships and Coalitions in Program Planning	479
18.3 Developing Program Goals and Measurable Objectives to Demonstrate Outcomes	487
Chapter Summary	491
Key Terms	491
Review Questions	492

CHAPTER 19

Planning Community Health Education 495

Introduction	495
19.1 Principles of Planning in Health Education Practice	496
19.2 Developing a Health Education Plan	499
19.3 Steps Involved in Planning Health Education Activities	507
Chapter Summary	512
Key Terms	512
Review Questions	512

CHAPTER 20

Implementation and Evaluation Considerations 515

Introduction	515
20.1 Facilitators and Barriers to Program Implementation	516
20.2 Recruitment and Retention of Program Participants	517
20.3 Evaluation Strategies	522
20.4 Communication Strategies	528
20.5 Funding and Sustainability	533
Chapter Summary	536
Key Terms	536

UNIT 5 CULTURALLY CONGRUENT CARE

CHAPTER 21

Cultural Influences on Health Beliefs and Practices

539

Introduction	539
21.1 Race, Ethnicity, Culture, and Nationality	540
21.2 Cultural Groups and Formation of a Cultural Identity	543
21.3 The Role of Culture in Shaping Health Beliefs and Practices	545
21.4 Overview of Cultural Views and Practices	549
21.5 Culture Matters in Addressing Health Inequalities	556
Chapter Summary	559
Key Terms	559
Review Questions	560

CHAPTER 22

Transcultural Nursing

563

Introduction	563
22.1 What Is Transcultural Nursing?	564
22.2 Cultural Models	564
22.3 Cultural Assessment	574
Chapter Summary	580
Key Terms	580
Review Questions	581

CHAPTER 23

Culturally and Linguistically Responsive Nursing Care

583

Introduction	583
23.1 Culture, Cultural Identity, and Cultural Humility	584
23.2 What Is Culturally Responsive Care?	585
23.3 Factors Affecting Culturally Responsive Care	589
23.4 Becoming a Culturally Responsive Nurse	591
23.5 Linguistically Responsive Care	596
23.6 Providing Culturally and Linguistically Responsive Care	598
Chapter Summary	601
Key Terms	601
Review Questions	602

CHAPTER 24

Designing Culturally and Linguistically Appropriate Programs

605

Introduction	605
24.1 Culturally Responsive Care	606
24.2 Health Care Tools to Identify Organizational Strengths and Areas for Improvement	614
24.3 The Nurse's Role in Promoting Organizational Cultural and Linguistic Competency	623
Chapter Summary	629
Key Terms	629
Review Questions	629

CHAPTER 25**Managing the Dynamics of Difference** 633

Introduction	633
25.1 Strategies to Promote Culturally Responsive Nursing	634
25.2 Root Causes of Stereotypes and Biases	636
25.3 Managing Conflict	646
25.4 Creating an Atmosphere of Trust and Mutual Respect	654
Chapter Summary	658
Key Terms	658
Review Questions	659

UNIT 6 CARING FOR POPULATIONS AND COMMUNITIES

CHAPTER 26**Health Promotion and Maintenance Across the Lifespan** 661

Introduction	661
26.1 Maternal Health	662
26.2 Newborn, Infant, and Toddler Health	675
26.3 Preschool, School-Age, and Adolescent Health	683
26.4 Adult Health	695
26.5 Older Adult Health	705
Chapter Summary	715
Key Terms	715
Review Questions	716

CHAPTER 27**Caring for Vulnerable Populations and Communities** 719

Introduction	719
27.1 People Who Are Experiencing Homelessness	720
27.2 Veterans	727
27.3 The LGBTQIA+ Community	730
27.4 Migrant Workers	736
27.5 People with Disabilities	741
27.6 Impact of Adverse Childhood Experiences	745
Chapter Summary	748
Key Terms	748
Review Questions	749

CHAPTER 28**Caring for Families** 751

Introduction	751
28.1 Family as Client	752
28.2 Frameworks of Practice	756
28.3 Family Health Nursing	759
28.4 Conducting a Family Nursing Assessment	762
28.5 Family Violence	767
Chapter Summary	774

Key Terms	774
Review Questions	775

CHAPTER 29

Caring Across Practice Settings 777

Introduction	777
29.1 Occupational Health	778
29.2 School Health	785
29.3 Correctional Nursing	799
29.4 Public Health Nursing and Public Health Departments	809
Chapter Summary	816
Key Terms	816
Review Questions	817

CHAPTER 30

Care Transition and Coordination Across the Community 819

Introduction	819
30.1 The Effects of Care Coordination and Care Transitions on Outcomes	820
30.2 Care Transition Models	828
30.3 Role of the Community Health Nurse	833
Chapter Summary	845
Key Terms	845
Review Questions	846

CHAPTER 31

Caring for Populations and Communities in Crisis 849

Introduction	849
31.1 Trauma-Informed Care	850
31.2 The Mental Health Crisis	852
31.3 The Opioid Epidemic and Substance Use Disorders	857
31.4 Human Trafficking	863
31.5 Refugees	868
Chapter Summary	873
Key Terms	873
Review Questions	874

CHAPTER 32

Principles of Disaster Management 877

Introduction	877
32.1 Types of Disasters	878
32.2 Biological Terrorism	885
32.3 Mass Violence	892
32.4 The Disaster Management Cycle	898
32.5 The Nurse's Role in Emergency Preparedness and Disaster Response	904
Chapter Summary	914
Key Terms	914

PREFACE

About OpenStax

OpenStax is part of Rice University, which is a 501(c)(3) nonprofit charitable corporation. As an educational initiative, it's our mission to improve educational access and learning for everyone. Through our partnerships with philanthropic organizations and our alliance with other educational resource companies, we're breaking down the most common barriers to learning. Because we believe that everyone should and can have access to knowledge.

About OpenStax Resources

Customization

Population Health for Nurses is licensed under a Creative Commons Attribution 4.0 International (CC BY) license, which means that you can distribute, remix, and build upon the content, as long as you provide attribution to OpenStax and its content contributors.

Because our books are openly licensed, you are free to use the entire book or select only the sections that are most relevant to the needs of your course. Feel free to remix the content by assigning your students certain chapters and sections in your syllabus, in the order that you prefer. You can even provide a direct link in your syllabus to the sections in the web view of your book.

Instructors also have the option of creating a customized version of their OpenStax book. Visit the Instructor Resources section of your book page on OpenStax.org for more information.

Art Attribution

In *Population Health for Nurses*, art contains attribution to its title, creator or rights holder, host platform, and license within the caption. Because the art is openly licensed, anyone may reuse the art as long as they provide the same attribution to its original source.

Errata

All OpenStax textbooks undergo a rigorous review process. However, like any professional-grade textbook, errors sometimes occur. In addition, the wide range of topics, data, and legal circumstances in nursing change frequently, and portions of the textbook may become out of date. Since our books are web-based, we can make updates periodically when deemed pedagogically necessary. If you have a correction to suggest, submit it through the link on your book page on OpenStax.org. Subject matter experts review all errata suggestions. OpenStax is committed to remaining transparent about all updates, so you will also find a list of past and pending errata changes on your book page on OpenStax.org.

Format

You can access this textbook for free in web view or PDF through OpenStax.org, and for a low cost in print. The web view is the recommended format because it is the most accessible – including being WCAG 2.1 AA compliant – and most current. Print versions are available for individual purchase, or they may be ordered through your campus bookstore.

About *Population Health for Nurses*

Summary

OpenStax *Population Health for Nurses* frames foundational knowledge nurses need to practice in the traditional fields of community and public health nursing—defining the breadth of the discipline, its methods and theories, and the central concept of health equity as well as incorporating the nursing process—all within the context of population health. The text prepares nurses to develop interventions, policies, and practices in collaborative partnerships that promote health equity and improved health outcomes across the health care delivery continuum, which includes public health, acute care, ambulatory care, transitional care, and long-term care.

Population Health for Nurses emphasizes the social determinants of health and health inequities and how nurses can plan and implement health promotion and disease prevention interventions to address them. It takes a holistic

perspective, connecting human health behavior to the dynamic, ongoing interactions of the person, social factors, and the physical environment in which people are born, live, learn, play, work, and age. The text encourages the critical analysis of implicit biases and practices that contribute to health inequities and presents strategies for designing culturally and linguistically appropriate programs. It challenges students to reflect on and critique their own biases, stereotypes, prejudices, and assumptions and to prioritize client self-determination in order to work effectively within each client's cultural context.

Pedagogical Foundation

OpenStax *Population Health for Nurses* uses a logical, thematic organization that breaks down content into manageable chunks. The text defines and distinguishes among the interrelated nursing areas of population health, public health, and community health nursing, providing both historical context and up-to-date research to help students make connections across content that can inform practice. The text takes a holistic approach that applies theoretical concepts to the practical assessment, diagnosis, planning, implementation, and evaluation steps of client care and community-tailored interventions.

Organizational Framework

Population Health for Nurses presents content in 35 chapters, organized into seven thematic units.

- **Unit 1: Preserving the Health of Populations and Communities** lays the foundation for the text. The opening chapters introduce the concept of population health and the interrelated practice specialties of public health and community health nursing. A description of the current health status of the U.S. population follows, along with a discussion of the role nurses play in creating a culture of health by promoting actions to achieve good health and well-being across geographic, demographic, and social sectors.
- **Unit 2: Issues and Challenges of Population Health** focuses on factors affecting access, delivery, and quality of care. The unit begins by describing current demographic and societal trends affecting health care and how those trends are rooted in and affected by structural racism and systemic inequities. The unit then goes on to discuss the major impacts of policies, regulatory conditions, and social determinants on population health and examines how they produce health disparities.
- **Unit 3: Population-Based Practice and the Tenets of Public Health** describes the specializations and methods that form the foundation of community and public health nursing practice, including elements integral to assessment, diagnosis, intervention, planning, and evaluation. These elements are presented together so that students can formulate a holistic perspective of human health behavior and the dynamic, ongoing interactions of the person, social factors, and physical conditions of their environment.
- **Unit 4: Merging Public Health Principles with the Nursing Process** teaches students how to apply the nursing process in a community setting. While nursing programs typically introduce students to the nursing process relatively early in the curriculum sequence, the concept is usually taught in the context of caring for an individual. The transition from caring for an individual to caring for a community or population requires students to view health and health needs through a different lens. This text helps students make this transition so that they can develop a holistic perspective of the social factors and physical conditions of the environment that should be taken into consideration when planning care for communities and populations.
- **Unit 5: Culturally Congruent Care** begins with an exploration of the cultural factors that influence client health beliefs and behaviors. It then describes perspectives on and approaches to providing culturally and linguistically appropriate care that can lead to positive health outcomes. Strategies for designing culturally and linguistically appropriate programs are discussed, and the unit ends with a chapter that focuses on how individual nurses can manage the dynamics of difference to create an atmosphere of trust and mutual respect. The chapters in this unit emphasize the importance of self-awareness and of prioritizing client self-determination.
- **Unit 6: Caring for Populations and Communities** focuses on the nurse's many roles in caring for populations and communities across the lifespan. Chapters in this unit address specific populations and care settings and place special emphasis on caring for vulnerable populations, including members of the LGBTQIA+ community and clients affected by mental illness, substance misuse, violence, and displacement. The final chapter in this unit addresses the public health nurse's role in disaster management.
- **Unit 7: The Nurse's Role as Advocate and Leader** challenges students to think critically about how they can use their position as nurses to promote social justice and health equity. Chapters in this unit highlight the importance of nurses' contributions as leaders in practice and policy issues aimed at achieving health for all.

Population Health for Nurses Features

To further enhance learning, *Population Health for Nurses* includes the following features:

- **Case Reflections** present a hypothetical client scenario, including pertinent information about the client's current health status and the demographic, social, and environmental factors that affect it. The scenario is followed by two or more open-ended questions about appropriate health promotion and disease prevention interventions across the health care delivery continuum, including public health, acute care, ambulatory care, and long-term care.
- **Unfolding Case Studies** present a hypothetical client scenario that unfolds in two or more parts throughout the chapter, with each subsequent part presenting new information on the same client. In each part of an unfolding case feature, the scenario is followed by two multiple-choice questions that require students to apply their knowledge of evidence-based client care. The answers to these questions, with explanations, are included in the Answer Key for students at the end of the book.
- **Healthy People 2030** features highlight Healthy People 2030 priority areas and objectives related to chapter topics.
- **The Roots of Health Inequities** features alert students to the root causes of inequities in the distribution of disease, illness, and death experienced by the population and/or community of focus.
- **Theory in Action** features use video clips, web links, and other media to demonstrate the application of a theory to nursing practice. These features help students see the practical purposes theory serves in their work with clients and their collaborations with other professionals. They include open-ended follow-up questions that can be used for individual student reflection or in-class discussion.
- **Conversations about Culture** features focus on culturally responsive nursing practice and diverse populations within the community. They often make use of one or more video clips, and each includes critical thinking and reflection questions aimed at challenging students to analyze how they solve problems, consider alternative solutions, and critically appraise actions to promote self-understanding and to evaluate their perceptions, beliefs, values, and behavior.
- **Client Teaching Guidelines** list points nurses should emphasize when providing client education, such as how to recognize signs of food poisoning and steps to take in case of a suspected drug overdose.
- **Additional Video, Podcast, and Hyperlinked Interactive Features** provide students with real-world examples, applications, and opportunities for critical thinking, reflection, and self-assessment.

Pedagogical Features

To support student learning, *Population Health for Nurses* includes the following standard elements:

- **Learning Outcomes.** Every major chapter section begins with a set of clear and concise student learning outcomes. These outcomes are designed to help the instructor decide what content to include or assign and to inform students of what they can expect to learn and be assessed on.
- **Review Questions.** This end-of-chapter feature presents 10 multiple-choice questions that require students to apply what they have learned and integrate chapter concepts. Answers to each question, with explanations, are included in the Answer Key for students at the end of the book.
- **Chapter Summary.** Chapter summaries assist both students and instructors by recapping the primary subtopics addressed within the chapter.
- **Key Terms.** Key terms are bolded and explained the first time they appear within the chapter. Definitions of these terms are listed at the end of each chapter.
- **References.** Chapter references are listed at the end of the book.

About the Authors

Senior Contributing Authors

Senior Contributing Authors: Jessica Ochs (left), Sherry L. Roper (center), and Susan M. Schwartz (right)

Jessica Ochs, Endicott College

Dr. Ochs is a Professor of Nursing at Endicott College and is a certified family nurse practitioner devoted to improving client health through clinical practice, education, program development, and research. She earned her DNP from Northeastern University and holds an MS degree from the University of Massachusetts. In her role as an advanced practice registered nurse, Dr. Ochs works with a diverse client population in primary care, urgent care, and community health. She is a Distinguished Scholar Fellow in the National Academies of Practice, and her research interests include social determinants of health and social change, interprofessional collaborative practice and education, and creating inclusive and engaging learning environments. Dr. Ochs's recent publications include an interprofessional public policy call for action, decreasing health disparities by addressing structural racism, and an innovative incorporation of the social determinants of health. Dr. Ochs maintains an active role in the National League for Nursing, the National Academies of Practice, Sigma Theta Tau International, and the American Association of Colleges of Nursing. The National League for Nursing awarded Dr. Ochs Nurse Educator of the Year in 2022, and in 2023, Dr. Ochs was presented with the Faculty of the Year Award at Endicott College.

Sherry L. Roper, California State University, Stanislaus

Dr. Roper is Associate Professor at California State University, Stanislaus, where she serves as the Assistant Director of the School of Nursing and the RN to BSN Program Director. She earned her BSN and MSN degrees from Pennsylvania State University and a distinguished PhD from the University of Tennessee, Memphis. Dr. Roper is a certified Small Group Facilitator of Improving Cultural Competency for Behavioral Health Professionals. Her research focuses on client-centered care, exploring the impact of potential biases on client outcomes, and addressing health disparities within the LGBTQIA+ community. Dr. Roper's published research highlights deficiencies in nursing education regarding the care of members of the LGBTQIA+ community, and she advocates for cultural humility to bridge the gaps in LGBTQIA+ health care. Dr. Roper's current research involves a comparative analysis of LGBTQIA+ health content in nursing education across the United States, the United Kingdom, and the Republic of Ireland. In addition, she leads a Collaborative Online International Learning (COIL) course that aims to enhance intercultural competence in addressing health disparities within the LGBTQIA+ community. Dr. Roper is an active member of the Transcultural Nursing Society, Sigma Theta Tau International Honor Society, and the American Association of Colleges of Nursing.

Susan M. Schwartz, Widener University

Dr. Schwartz is an Assistant Professor at the School of Nursing, Widener University. She earned a PhD at Harvard University, MSN at West Chester University, MA at Harvard University, BSN at the Johns Hopkins University School of Nursing, and BA from the University at Albany, SUNY. Having obtained doctoral education in anthropology prior to becoming a health care professional, she brings a unique perspective to nursing and nursing education. Dr. Schwartz uses her expertise to develop and direct global immersion and experiential programs abroad, bringing nursing students to work with the Maya of Guatemala, remote communities in the Amazon, and the favelas of Salvador de

Bahia, Brazil. She has received numerous awards including Outstanding Nurse Educator Award at Rutgers University, Excellence in Teaching at Harvard University, and Faculty Delegate to the University of Havana and has served as a Civic Engagement Faculty Fellow at Rutgers University and Academic Service-Learning Faculty Fellow at Widener University. Dr. Schwartz studies the intersection of social and cultural determinants and health inequities among human trafficking victims with the objective of providing culturally responsive, trauma-informed care within a social justice framework. Dr. Schwartz aims to use her research to educate nursing students on the provision of holistic, culturally responsive care for vulnerable populations. Her work has been supported by the Mellon Foundation, the David Rockefeller Center for Latin American Studies at Harvard University, Dumbarton Oaks, and numerous grants from the Centers for Global Advancement and International Affairs at Rutgers University. Dr. Schwartz was honored as a Nurse Leader by Sigma Theta Tau in 2014, serves on numerous professional boards, and was unanimously elected president of CONAA in 2019.

Nursing Consultants

The authors would like to thank nursing consultants Amy B. Britt, Bon Secours Mercy Health, and Marcy Caplin, Associate Professor, Kent State University College of Nursing, for their expertise and assistance with content review and development.

Academic Integrity

Academic integrity builds trust, understanding, equity, and genuine learning. While students may encounter significant challenges in their courses and their lives, doing their own work and maintaining a high degree of authenticity will result in meaningful outcomes that will extend far beyond their college career. Faculty, administrators, resource providers, and students should work together to maintain a fair and positive experience.

We realize that students benefit when academic integrity ground rules are established early in the course. To that end, OpenStax has created an interactive to aid with academic integrity discussions in your course.

(attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Visit our [academic integrity slider \(<https://openstax.org/r/viewgenially>\)](https://openstax.org/r/viewgenially). Click and drag icons along the continuum to align these practices with your institution and course policies. You may then include the graphic on your syllabus, present it in your first course meeting, or create a handout for students.

At OpenStax we are also developing resources supporting authentic learning experiences and assessment. Please visit this book's page for updates. For an in-depth review of academic integrity strategies, we highly recommend visiting the International Center of Academic Integrity (ICAI) website at <https://academicintegrity.org/>

(<https://openstax.org/r/academicintegrityor>).

Community Hubs

OpenStax partners with the Institute for the Study of Knowledge Management in Education (ISKME) to offer Community Hubs on OER Commons—a platform for instructors to share community-created resources that support OpenStax books, free of charge. Through our Community Hubs, instructors can upload their own materials or download resources to use in their own courses, including additional ancillaries, teaching material, multimedia, and relevant course content. We encourage instructors to join the hubs for the subjects most relevant to your teaching and research as an opportunity both to enrich your courses and to engage with other faculty. To reach the Community Hubs, visit www.oercommons.org/hubs/openstax.

Technology Partners

As allies in making high-quality learning materials accessible, our technology partners offer optional low-cost tools that are integrated with OpenStax books. To access the technology options for your text, visit your book page on OpenStax.org.

Special Thanks

The Division of Digital Learning at the Texas Higher Education Coordinating Board (THECB) has a history of dedicated research initiatives, services, and programs that have advanced open education in Texas by providing support, advocacy, and resources to Texas institutions in their OER efforts. The Division maintains a diverse OER portfolio including OERTX, a digital library and community space for open education work. The leadership and collaboration of the Division of Digital Learning staff made the OER Nursing Essentials (ONE) project possible, throughout research, planning, and development phases of the eight-textbook series.

This work was supported in whole or in part by the THECB. The opinions and conclusions expressed in this document are those of the author(s) and do not necessarily represent the opinions or policies of the THECB.

CHAPTER 1

What Is Population Health?

FIGURE 1.1 The family pictured here is enjoying a fishing expedition. Clean, safe outdoor space where people can go to exercise, socialize, and relax is important to health promotion and risk reduction. (credit: modification of work “Family fishing Leesylvania State Park” by Virginia State Parks/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 1.1 Defining Population Health
- 1.2 Why Population Health Is Important
- 1.3 Population-Based Practice in Nursing

INTRODUCTION Alexandra Lee, a 37-year-old day care teacher, works from 8:00 a.m. to 4:30 p.m. five days a week. Alexandra wakes up early to prepare breakfast for her husband and two children, then commutes to work via public transportation. She is currently 30 weeks pregnant. Thus far, her blood pressure readings have been healthy throughout her pregnancy. Keeping her stress level low has been challenging, as her husband, Christopher, recently lost his job, and few employers are hiring. As a Black woman, Alexandra is at risk for experiencing adverse pregnancy outcomes resulting from systemic racism and bias in the health care system. For example, Black pregnant people are four to five times more likely to die of a pregnancy-related cause than White pregnant people (Petersen et al., 2019). One potential cause of death is preeclampsia, a condition involving dangerous elevations in blood pressure. Black pregnant people, like Alexandra, have a higher prevalence of preeclampsia and its devastating complications than White pregnant people, and anti-Black racism in the health care system is one contributing factor (Ukoha et al., 2022; Zhang et al., 2020). Chapters 1, 2, and 3 will follow Alexandra Lee and her family to explore how population, public, and community health impact their well-being.

Nurses play a central role in advancing population health; however, many nurses and the public may be unaware of the vital contributions of population health to client well-being. When considering where nurses work, many people think about hospitals and clinics. They might think about clients who need surgery, have broken a bone, are having a baby, or are not feeling well when they think of the people for whom nurses provide care. In addition to caring for

clients with acute illnesses and chronic conditions in care centers, however, nurses advance health, lead change, and impact society through contributions to population health, public health, and community health. These three areas may sound similar, as though they are interchangeable terms for the same work; however, population health is similar to but distinct from public health and community health nursing practice. In brief, population health nursing focuses on the health status and health outcomes of groups of people, while public/community health is a broad discipline that consists of organized efforts to develop, implement, evaluate, and revise policies and programs to support the well-being of all people. Public health extends beyond nursing; its principles provide the foundation for population health and for public health and community health nursing practice. Chapters 2 and 3 will discuss public health and community health theory and practice in more detail.

Chapters throughout this text will introduce Healthy People 2030 goals and initiatives in boxes like the one that appears below. Healthy People 2030 is an important U.S. government program that addresses health topics involving population, public, and community health. The U.S. Department of Health and Human Services (USDHHS) sets Healthy People objectives every 10 years. In 2020, the USDHHS introduced 358 measurable health objectives that it hopes to achieve by the year 2030. It also identified health areas needing further development or research. The broad health areas identified in Healthy People 2030 include goals related to chronic diseases, health behavior, the environment, maternal-child health, violence prevention, and mental health, among others. The Healthy People 2030 program regularly shares updates regarding the progress toward these goals, so some chapter notes about this program may differ from what is available online based on the current status of the goals at the time of this text's publication. Be on the lookout for boxes in each chapter labeled Healthy People 2030 to learn more about these national population health priority areas.

HEALTHY PEOPLE 2030

Increase Core Clinical Prevention and Population Health Education in Nursing Schools

Healthy People 2030 includes a developmental goal of increasing the [inclusion of core clinical prevention](https://openstax.org/r/healthgovhe) (<https://openstax.org/r/healthgovhe>) and population health concepts in undergraduate and graduate nursing programs. This is a *developmental* goal because there were not enough baseline data before the Healthy People 2030 program regularly began to report how many nursing programs were already including such content. However, there are enough data to say that, for the nation's health, future health care professionals must be ready to address population health and prevention in their work. Similarly, the Healthy People 2030 program has developmental goals for increasing clinical prevention and population health content for medical, physician assistant, pharmacy, and dental programs, as well as interprofessional prevention education content for health profession programs in general.

1.1 Defining Population Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 1.1.1 Define population health.
- 1.1.2 Explain the origin of the population health approach.
- 1.1.3 Identify the components of population health.
- 1.1.4 Discuss the global application of population health.

Population health is a comprehensive approach that spans the entire health care continuum, from public health prevention to disease management. Population health aims to support the health of people through diverse activities, including care coordination, health care research, population-level data analysis, and health programming. Activities carried out to improve population health generally support the health status and health outcomes of groups of people rather than one client at a time. Population health interventions take a more holistic approach than those that are generally used in the care of individual clients. Population health considers the impact of public policy and law as well as environmental, social, behavioral, and other factors that might facilitate or hinder health for all people. The requisite knowledge of these disciplines and health areas comes together to address many factors that can influence health.

Consider tobacco use, which, as the [leading cause of preventable death](https://openstax.org/r/cdcgovtobacco) (<https://openstax.org/r/cdcgovtobacco>) in

the United States, kills an estimated 1,300 Americans each day. Individual counseling and interventions such as prescription medications and nicotine gum can help individuals quit smoking. While a population health approach to addressing tobacco smoking cessation would support the availability of individual tools, it would also consider the broader factors contributing to smoking rates and smoking uptake across the population. A population health approach to smoking cessation might include the following:

- Developing community-wide antismoking campaigns
- Advocating for schools, businesses, restaurants, and other public places to develop smoke-free policies
- Researching the reasons that community members start or do not quit smoking
- Analyzing population-level data to identify trends in smoking
- Passing legislation to increase taxes on tobacco products to discourage their purchase and fund population health programs focused on cessation

Overall, a population health approach that considers the multifaceted facilitators and deterrents of smoking can help reduce smoking rates, thereby improving the health of smokers and the population at large.

Drunk driving is another example of a serious public health problem. The [National Highway Traffic Safety Administration \(https://openstax.org/r/nhtsagovri\)](https://openstax.org/r/nhtsagovri) estimates that in the United States, one person is killed due to drunk driving every 39 minutes. Drunk driving impacts not only the life of the victim but also the lives of their friends, family, and community, and those of the driver as well. Individual-level interventions that work to improve the health of drivers and of community members to whom a driver may pose a risk include individual counseling, installing breathalyzer car ignition devices, and levying fines or revoking driver's licenses to hold drivers accountable and prevent future drunk driving occurrences. Population health interventions go beyond those aimed at specific drunk drivers. A population health approach to drunk driving reduction could include the following:

- Developing and implementing stricter laws and regulations regarding alcohol use and driving
- Leading campaigns to raise awareness about the dangers and penalties of drunk driving
- Collaborating with taxi companies and ride-share programs on weekends and holidays to offer free or reduced rides
- Training servers, bartenders, and liquor store employees on the responsible service and sale of alcohol
- Identifying high-risk areas for drunk driving accidents to increase signage and safety checks in these areas

In nursing, a **population** is a group of people that may receive care in various settings at the local, regional, national, and global levels (American Association of Colleges of Nursing [AACN], 2021). Examples of populations include all students at a specific college campus (local), all people who live or work in Northern California (regional), all residents of the United States (national), or all children with asthma across nations (global). The **health care continuum** encompasses public health, acute care, ambulatory care, and long-term care to collectively address a population's diverse health needs. The health care continuum and the role of nurses will be discussed further later in the chapter.

Population health involves collaborative efforts among health care professionals, communities, industries, academia, and governmental organizations to improve health outcomes among a population (AACN, 2021). A myriad of efforts in population health can explain or address why some populations are healthier than others and help determine how resources might be allocated to have the greatest impact on improving health across the population. As the smoking cessation and drunk driving examples illustrate, population health approaches focus on implementing education, policy, and programming that provide optimal outcomes for the money, time, and other resources invested. Nurses working in many settings—such as hospitals, schools, homes, communities, industries, and businesses—not only support but also shape population health across the United States (Ariosto et al., 2018). Nurses are critical in advocating for policies, implementing interventions, and ensuring that diversity, equity, inclusion, justice, and ethics are prioritized to achieve population health goals focused on health promotion, disease prevention, risk reduction, and emergency preparedness (AACN, 2021).

There is no definitive history of exactly when population health emerged and evolved into what health care providers, teams, and organizations know it as today (Sreter, 2003). Scholars note several defining moments from the 18th century through the modern day, such as observations of differences in health conditions between the wealthy and the impoverished, among people employed in various industries, and between those with and without access to clean water (Bynum, 1983; LaBerge, 1993; Porter, 1991). These historical moments allowed for

recognition of the relationship between a healthy human population and a healthy, functioning society. Although population health concepts and principles have been relevant to professional nursing practice for centuries, in the United States the passage of the Patient Protection and Affordable Care Act (ACA) in 2010 is credited with beginning to shift the focus of health care services from treating diseases in individual people to promoting health among populations (Ariosto et al., 2018). Emphasizing preventive efforts and proactively facilitating health instead of reactively treating diseases as they occur is a central tenet of population health. The shift is essential, as many recognize that a U.S. health care system that spends an estimated 75 to 90 percent of its resources addressing diseases and hospitalizations and invests very little in preventive efforts is a system that is failing (Raghupathi & Raghupathi, 2018; Shrunk et al., 2019; Centers for Disease Control and Prevention [CDC], 2023). By shifting the focus from reactive disease treatment to proactive health promotion, population health offers a more positive path forward. Under a population health–focused system, health care professionals are encouraged to work collaboratively to promote early intervention, provide health education, empower clients, and effect social change to reduce the burden of disease for individuals and the health care system at large.

The Quintuple Aim

Population health can impact numerous specific conditions, diseases, and health risks through interventions that cross disciplines and support a great breadth and depth of positive health change. As a field of study and practice, population health works toward specific aims developed by the Institute for Healthcare Improvement (IHI). In 2007, the IHI developed a framework called the [Triple Aim](https://openstax.org/r/ihorgE) (<https://openstax.org/r/ihorgE>) to support optimal performance of the health care system (Berwick et al., 2008). In 2014, the IHI updated the framework to the Quadruple Aim to acknowledge that the health of providers and other health care professionals must be supported to achieve population health goals (Bodenheimer & Sinsky, 2014). Today, the four aims consist of:

1. improving the client experience of care (including quality and satisfaction),
2. improving the health of populations,
3. reducing the per capita cost of health care, and
4. improving the well-being of health care professionals.

Recently, experts have suggested a revision to create the [Quintuple Aim](https://openstax.org/r/ihorgcom) (<https://openstax.org/r/ihorgcom>), which would include a fifth aim of advancing health equity. In both the fourth and suggested fifth aim expansions, experts have posited that improving population health, client experience, and health cost would be impossible without addressing provider health and burnout or health equity (Bodenheimer & Sinsky, 2014; Nundy et al., 2022). Concepts of the Quintuple Aim can guide evaluations of population health programs and initiatives. For example, telemedicine connects to the goals of improving the health of populations, improving the well-being of health care professionals, and advancing health equity. Its services offer several conveniences to clients and clinicians, such as the flexibility to dial in from home and save on commuting fees. These services also remove barriers to receiving care and increase equity in opportunity for clients to see primary care providers and specialists. This can help reduce inequities and disparities with regard to receiving screenings, diagnoses, and treatments for health conditions, which in turn can help improve population health. Telehealth is a growing initiative across health care globally; please see [Care Transition and Coordination Across the Community](#) for more information on telehealth. Recently, one research team determined that pediatric telehealth has advanced pediatric care in general so that it has become a better-performing, more equitable system (Cahan et al., 2020). Whether a population, community, or health system elects to use the version with three, four, or five aims, this framework encourages consideration of the interplay among the different aims and innovative approaches to improving health and health outcomes for the population.

Components of Population Health

Population health takes a comprehensive approach that accounts for the complex dynamics among differences in health status, community resources, personal characteristics, familial circumstances, and other factors that can trigger or aggravate health conditions. By recognizing the complex interplay of these numerous and wide-ranging factors, population health takes a holistic view to promote the well-being of all.

Regardless of the situation or specific factors, a guiding theme of population health is the importance and value of taking proactive rather than reactive approaches to improving health. An analogy to summarize population health involves an overflowing sink. Imagine a kitchen faucet is left running unattended, creating a giant puddle on the

floor. Better get a mop! Without population health, much of health care focuses on “mopping the floor” instead of “turning off the faucet” (Kaminski, 2021). In other words, health care as a system largely deals with floods—that is, helping clients who are already sick—instead of turning off the water, or addressing the situations and circumstances that make clients sick in the first place. Health care providers, nurses, policymakers, and the health care system at large should focus on the *causes* of health problems to prevent them before they occur, instead of focusing primarily on treating diseases as they happen. Of course, clients, families, and communities need access to treatment for their health conditions—but what if there was a way to prevent the conditions from happening in the first place?

Four key health concepts have been essential in advancing population health: outcomes, disparities, determinants, and risk factors.

Outcomes are all possible results. Health outcomes are indicators or data points that reflect the degree to which health interventions, care, policies, and behaviors are effective in supporting the health status of populations. Examples of health outcomes include mortality rates, life expectancy, disability rates, birth rates, health care costs, and health-related quality of life measures. Outcomes may come from exposure to interventions that aim to prevent or treat a condition, or they may result from exposure to health risks or situations detrimental to health. For example, creating a policy that allows people under a certain income level to have free health insurance may produce a range of outcomes, including insuring a greater percentage of the population and increasing the number of people who attend wellness exams—and, consequently, increasing the number of people who smoke who may be offered smoking cessation resources. On the other hand, removing or relaxing policies that prohibit smoking in public places may produce quite a different range of outcomes, including making it more difficult for people to quit smoking, exposing more people to secondhand smoke, and increasing rates of children who start smoking.

Disparities are inequalities or differences. A related concept is **health inequities**, which are avoidable inequalities related to health that stem from a form of injustice (Kawachi et al., 2002; McCartney et al., 2019). For example, children attending the Lincoln School may have higher rates of asthma than children attending the Washington School. The children are all the same age and have the same racial and ethnic distribution, but the parents of children at the Washington School have a higher average income and donated money so that each classroom could have an air conditioner. There is a disparity in access to clean air, as well as in rates of asthma, between children at these two schools. [Health Disparities](#) covers this topic in greater detail.

Determinants are the innumerable factors that influence health and generally include nonmedical events, characteristics, or other entities that change a health condition or the level of a health problem (Kindig, 2007; Office of Disease Prevention and Health Promotion, 2022). Within population health, determinants of interest include medical care, public health interventions, income, education, employment, social support, culture, clean air and water, outdoor space, genetics, and behavior (Kindig, 2007). Determinants can interact with each other to bolster health or worsen a problem ([Figure 1.2](#)). For example, when a client is unable to finish high school, they may not qualify for a full-time job that pays a living wage and offers access to a health insurance plan. Such a situation would undoubtedly impact the client’s ability to seek care when needed and to engage in health promotion efforts.

Social determinants of health are additional factors that influence the health of populations, families, and individuals. **Social determinants of health** are conditions and social factors that affect outcomes and risk related to health, functioning, and quality of life. Conditions or factors in hospitals, clinics, workplaces, homes, towns and cities, schools, and beyond influence health outcomes for the population. Economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context are five domains that shape the social determinants of health (Office of Disease Prevention and Health Promotion, 2022). Please see [Social Determinants Affecting Health Outcomes](#) for a comprehensive discussion of social determinants of health.

Risk factors are aspects of personal behaviors, lifestyle choices, exposures, or attributes that generally increase the likelihood of acquiring or the severity of a health condition. Risk factors are similar to determinants but tend to be more specific. Consider respiratory disease determinants and risk factors. Air quality and environmental pollution are determinants of respiratory disease, while smoking is a risk factor for respiratory disease. Some determinants may be risk factors; however, other determinants may reduce health risk.

FIGURE 1.2 This photo was taken during the 2018 Klondike Fire in Oregon. In addition to threatening human lives and homes, wildfires severely impact air quality, release harmful pollutants, and devastate wildlife and ecosystems. (credit: “Forest road 2512 and smoke-filled air, Klondike Fire” by U.S. Forest Service-Pacific Northwest Region/Flickr, Public Domain)

HEALTHY PEOPLE 2030

Tobacco Use

Healthy People 2030 developed 25 measurable objectives, one developmental objective, and one research objective to address tobacco use. Since creating [these objectives](https://openstax.org/r/healthgovhealth) (<https://openstax.org/r/healthgovhealth>), three targets have been met or exceeded: reducing cigarette smoking in adolescents, reducing the use of smokeless tobacco products among adolescents, and reducing the lung cancer death rate.

SOCIAL DETERMINANTS OF HEALTH

[Access multimedia content](https://openstax.org/books/population-health/pages/1-1-defining-population-health) (<https://openstax.org/books/population-health/pages/1-1-defining-population-health>)

Social determinants affect how environments where people live, work, and play impact health and well-being for all. This video explains different social determinants of health in depth.

Watch the video, and then respond to the following questions.

1. What is the greatest risk to economic stability in the community around your nursing school?
2. How does your nursing school support educational access and quality?
3. Do clients in the community by your nursing school have adequate access to health care?
4. Can you identify three risks and three supports in the neighborhood and built environment around your nursing school?
5. In your nursing school, what experiences do you participate in that contribute to the growth of the social community and context?

Additionally, population health focuses on upstream, midstream, and downstream approaches to improve health outcomes ([Figure 1.3](#)) (Salmond & Allread, 2019).

- **Upstream** interventions involve enacting policies that change regulations, increase access, or provide economic incentives to impact health across a population. Examples include policy changes regarding the fast

food or tobacco industry, provision of universal health care, and compensation for hospitals with lower inpatient admission rates (Porter et al., 2022).

- **Midstream** approaches are those that happen within specific organizations. For example, a workplace may provide healthy lunches to employees each day (Porter et al., 2022).
- **Downstream** interventions focus on the behavior of individual people to modify the risk of disease, prevent illness, or manage chronic conditions (Brownson et al., 2010; Fornili, 2022). For example, a nurse might counsel a client with hypertension about consuming a low-salt diet.

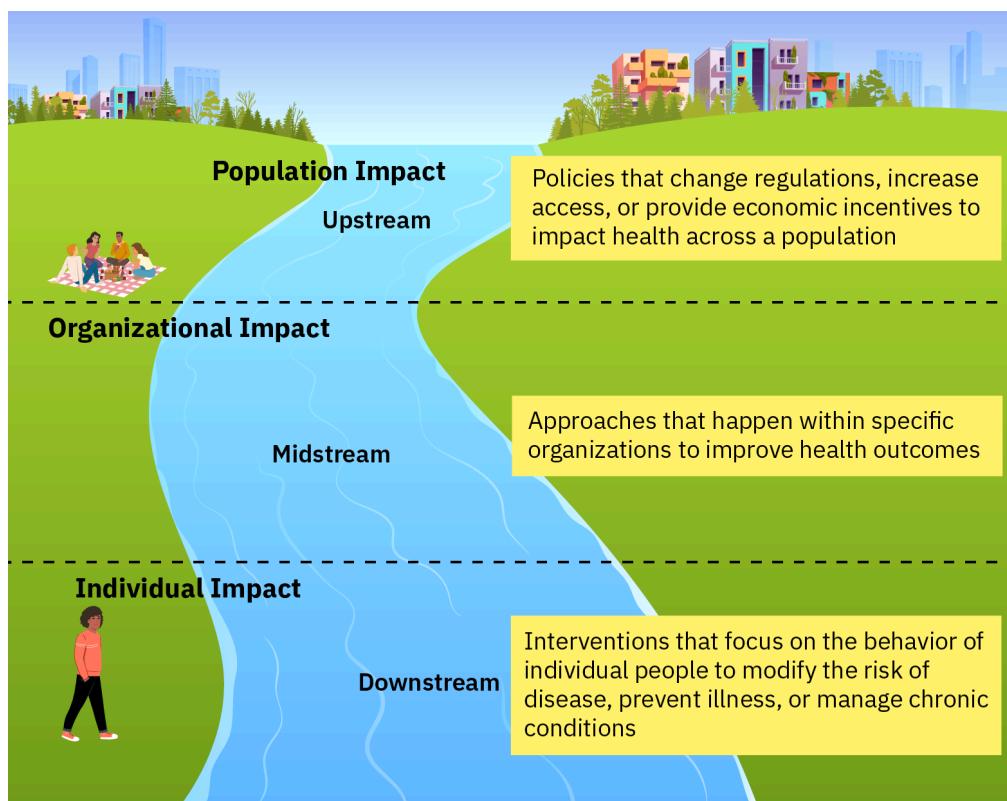

FIGURE 1.3 Population health involves the complex interactions of upstream, midstream, and downstream interventions. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

These key components interact in complex and evolving ways as population health and the health status of the population change over time. By employing upstream interventions, such as policy changes and universal health care, population health addresses the societal factors that impact the health of the population on a broad scale and ultimately the health of individual clients. Midstream approaches can contribute to fostering healthier environments in diverse settings. Downstream interventions, such as those that focus on individual behavior to support health, are also important in a population health model, as members of the population will never be fully free of health conditions requiring treatment. Together, upstream, midstream, and downstream approaches offer a framework for population health programming and interventions that can create positive health outcomes.

CASE REFLECTION

Components of Population Health

Read the scenario, and then respond to the questions that follow.

Forty-year-old Christopher Lee has hypertension. Although he has not attended a health checkup in a few years, he feels that his blood pressure might be lower since he lost his job. Being unemployed has been stressful, but as a Korean American, he experienced anti-Asian sentiment and discrimination from his coworkers during the COVID-19 pandemic. The Lees' 5-year-old daughter, Sunshine, just started kindergarten and has an EpiPen for a life-threatening nut allergy. She attended an after-school arts and crafts program twice a week but stopped going when

Christopher lost his job. The Lees' 2-year-old son, Woody, is generally healthy and attends the day care where Alexandra works. Christopher's parents live in South Korea and will visit the United States in a few months to help when the Lees' new baby is born.

1. Based on what you now know about the Lee family, what are some possible health challenges they may face?
 2. What are some possible upstream factors influencing their actual or potential health challenges? Are there any midstream and downstream factors that might support or harm their health?
-

Global Population Health

The need to address the factors and components of population health is a global one, and given the interconnected nature of the health status of people around the world, nurses should prioritize and actively contribute to enhancing global population health in addition to advancing local and national population health programs, goals, and outcomes. Many people around the world face significant challenges to promoting their health, receiving treatments, and reducing health risks. Health outcomes, disparities, determinants, risk factors, and upstream, midstream, and downstream influences are all relevant and crucial to improving global population health. The health status of people as far away as a different continent on other side of the equator can impact the health of clients locally, and nurses have a responsibility to support efforts that advance population health worldwide (Hong & Lee, 2021; Wilson et al., 2016). Nurses have a duty to extend their care, genuine concern, empathy, and compassion to those in need beyond their immediate surroundings. To that end, a global advisory panel on the future of nursing proposed a definition of global nursing:

Global nursing is the use of evidence-based nursing processes to promote sustainable planetary health and equity for all people. Global nursing considers social determinants of health, [and] includes individual and population-level care, research, education, leadership, advocacy, and policy initiatives. Global nurses engage in ethical practice and demonstrate respect for human dignity, human rights, and cultural diversity. Global nurses engage in a spirit of deliberation and reflection in interdependent partnership with communities and other health care providers. (Wilson et al., 2016, p. 1537)

When nurses engage in global nursing, they can proactively contribute to bettering population health and reducing the global burden of disease, health conditions, disability, and disparities. By embodying a commitment to global nursing, nurses can positively impact and improve the lives of others and uphold the principles of the discipline. Almost any health issue, concern, condition, or topic can be a global population health problem needing solutions.

Climate Health

People living in the western United States may recall having “smoke days” off from school due to poor air quality from wildfire smoke, while those from the East Coast and Midwest may recall a few days in June 2023 when the skies were tinted orange and air quality was exceptionally poor due to wildfire smoke movement from Canada. That same summer, wildfires burning out of control across Greece caused the evacuation of 19,000 people (Smith & Chrisafis, 2023). Exposure to wildfire smoke and poor air quality impacts the health of humans and animals alike. It exacerbates respiratory conditions, may cause congenital anomalies, and can even contribute to lower academic performance for students (Amjad et al., 2021; Gan et al., 2020; Wen & Burke, 2022). Wildfires are one example of an extreme weather or climate event that causes significant harm to mental health and well-being and contributes to morbidity and mortality around the globe (Ebi et al., 2021).

In addition to causing wildfires, extreme weather—in the form of high temperatures, torrential rains, and prolonged drought—puts the health of the population at risk around the world. The levels of extreme heat that were experienced across Asia, Europe, and the United States during the summer of 2023 are enough to worsen existing respiratory conditions and cause heat stroke, a life-threatening emergency (CDC, n.d.). Heavy rains and flooding can contribute to the development of climate-sensitive infections like malaria, dengue, diarrheal diseases, and emerging infections, as disease-causing pathogens are able to thrive in the unusually wet conditions (Choisy et al., 2022). Global climate scientists are particularly concerned about the effects of climate change in Asia, where temperatures have been rising two times faster than in other parts of the world (Dabla-Norris et al., 2021). Climate health is truly a global health concern.

Supporting climate health is a key priority area in population health nursing; see [Environmental Health](#). Participating

in global nursing allows nurses to address the impact of extreme weather events on the health of the global population. Nurses can provide care that mitigates the health effects of climate events, promote policies that support global climate health, and collaborate to ensure equitable access to a healthy local and global climate.

Vaccines

In the United States, COVID-19 vaccines were available to health care workers and older adults living in long-term care facilities in late 2020 and to the general public in spring 2021. The global population of health care workers, clients, and families did not have the same timely access to vaccines. High-income countries had purchased 54 percent of the world's available vaccine doses by March 2021, but 81 percent of the global adult population lives in low- and middle-income countries (Stephenson, 2021). Disparities in vaccine access were detrimental to immediate and long-term global population health outcomes and contributed to avoidable deaths. Nurses addressing global population health can advocate for equitable worldwide vaccine distribution, provide education on the importance of vaccination to those who require vaccines and those who determine where vaccine clinics may be located, and provide timely access to vaccine administration ([Figure 1.4](#)).

FIGURE 1.4 A health care worker vaccinates a client in a vaccine clinic in Colombia. The sign in the background reads *Vacuna es segura*, which means “The vaccine is safe.” Beyond the challenges of quickly developing a vaccine, making enough for the global population, and handling logistics such as transportation and storage, a major barrier to global health in 2021—and to ending the COVID-19 pandemic—was informing the public that the vaccine was safe and effective. (credit: “Colombia COVID-19 Vaccine at Mobile Site” by USAID/Colombia/Flickr, Public Domain)

Transportation

Access to health care can mean many things. Is there a provider or specialist in the client’s area who can adequately address the client’s health needs, and is that provider or specialist accepting new clients? Is a health care professional available who speaks the client’s native language to facilitate clarity during a health visit? Can the client physically get to a location providing health care services? Researchers recently determined that 8.9 percent of the global population is not able to access a health care provider within one hour by vehicle (Weiss et al., 2020). The time it takes a client or family to reach a health care facility can impact whether the client receives preventive health care, emergency services, and management of chronic conditions. For example, accessibility to emergency care services has a great impact on the health of people who are having a stroke, as certain medical interventions must be implemented during specific time frames from the onset of stroke symptoms (Lee et al., 2021). To support population health outcomes related to care access, nurses should contribute to developing innovative solutions for improving transportation options to ensure that people can reach facilities for care needs across the continuum. Global population health is also supported when nurses bring health care to homes and communities with low access.

WHY SHOULD YOU CARE ABOUT GLOBAL HEALTH?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/1-1-defining-population-health>\)](https://openstax.org/books/population-health/pages/1-1-defining-population-health)

In this video, Dr. Deboki Chakravarti, a science educator with the American Public Health Association, discusses global health. She addresses the major challenge in global health—helping people live the healthiest possible lives, regardless of where they live—and shares how some examples of global health problems, such as global disease eradication, food distribution, health access, and COVID-19 vaccine refrigeration, were solved via collaborative solutions.

Watch the video, and then respond to the questions that follow.

1. Can you name one way in which global nursing approaches may have supported the global health topics Dr. Chakravarti shares in the video?
2. What other global population health challenges are you aware of? What can nurses near to and far from the immediate health challenges do to address these problems?

1.2 Why Population Health Is Important

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 1.2.1 Discuss the importance of promoting the health of populations.
- 1.2.2 Examine the benefits of a healthy population.

Promoting the health of populations is essential to providing health care, not just illness care. Think back to the analogy about turning off the faucet or mopping the floor. Will clients and communities be best served when health care providers prevent illness and promote health (turn off the faucet) or when they treat conditions as they arise (mop the floor)? When population health is promoted, all can benefit from improved health outcomes, cost savings, social benefits, equity, and justice.

Health Promotion Outcomes

Health promotion activities and initiatives aim to improve health and well-being. These activities can be delivered to individuals (e.g., helping a client plot a safe walking route between home and work) or populations (examples are discussed later in this section). Health promotion involves a broad range of strategies, educational initiatives, interventions, and even health policies that empower populations to reduce health risks and engage in healthy behaviors, making it possible for them to achieve health. Health promotion outcomes involve changes in knowledge, skills, attitudes, and various health indicators. Outcomes are used to evaluate the efficacy, feasibility, cost-effectiveness, or success of health promotion interventions across the population. Identifying outcomes and collecting data related to those outcomes allow for measurement of progress and any needed program redesign and can support decisions to continue, broaden, or perhaps retire certain programs.

Health promotion and disease prevention efforts at the population level can raise national health indicators. National health indicators provide an overview or snapshot of the population's health status, enabling assessment of national trends. These indicators include general mortality, infant mortality, and life expectancy (U.S. Environmental Protection Agency, 2022).

- **General mortality** refers to the number of deaths across an entire large population, such as those living in a geographic region or a country. Reports of general mortality include information about leading causes of death across the population and estimates of years of potential life lost when people die prematurely. For example, firearm injuries are the leading cause of death of children and adolescents aged 1 to 19 years in the United States and contribute to a collective 1.26 million years of potential life lost per year (Goldstick et al., 2022; Klein et al., 2022).
- **Infant mortality** rates measure the number of infants who die before their first birthday. In 2020, the U.S. infant mortality rate was 5.42 infant deaths per 1,000 live births (Ely & Driscoll, 2022).
- **Life expectancy** is the average number of years that a newborn is expected to live if current death rates remain constant. U.S. babies born in 2022 have an estimated life expectancy of 76.33 years ([Figure 1.5](#))

(Noguchi, 2022).

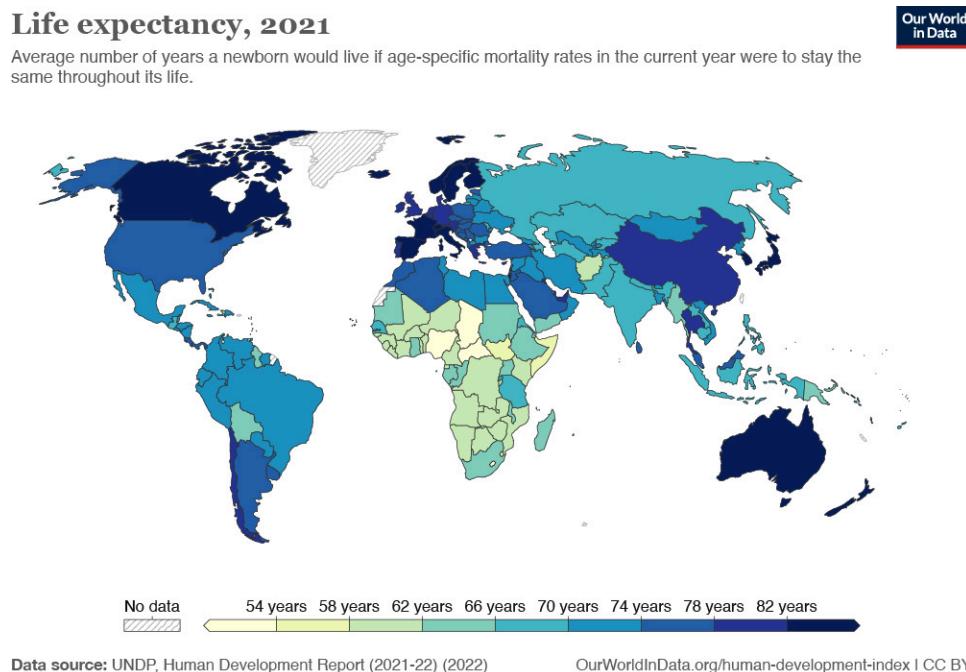

FIGURE 1.5 This map shows average life expectancy rates around the world for 2021. (credit: “Life expectancy, 2021” by Our World in Data, CC BY 4.0 International)

These national health indicators provide information at the macro level, offering a larger-scale perspective of the health system. National health indicators do not focus on individual behaviors or data relevant to one location or community. For example, knowing that firearm injuries are the leading cause of death in children and adolescents alone will not direct nursing practice on exactly how to prevent firearm injuries. However, knowing this fact can direct nurses of any specialty or practice area to recognize the critical importance of addressing firearm use and availability as part of a comprehensive approach to preventing tragic and avoidable deaths in the population of American children. Although these national health indicators are broad, analyzing them can allow for informed decisions on prioritization of public health interventions and resource allocation to support population health. There are many benefits of having a healthy population and improving the national health indicators of general mortality, infant mortality, and life expectancy. Beyond these three key outcomes, population health often focuses on the following outcomes:

- **Morbidity rate** reflects the prevalence or incidence of a specific health condition, disease, or diagnosis within the population. For example, approximately 1 in every 13 people in the United States has asthma (National Center for Health Statistics, 2021a, 2021b).
 - **Health care utilization** helps report the extent to which a population accesses and uses different health care services. Data may include measurements of hospital admissions, lengths of stay, hospital readmissions, emergency room visits, acceptance of immunizations, completion of annual physicals, engagement with preventive screenings, and many other points of contact between the health system and members of the population. For example, one study found that 98.8 percent of adults seeking care for back pain in the United States do not have surgery. Though they avoid costly surgery, the total collective cost of their care per year is estimated at \$1.8 billion (Kim et al., 2019).
 - **Quality of life** measurements allow for a comprehensive, multidimensional evaluation of the physical, mental, and social well-being of the population. Combining measurements and perspectives from many different areas of life allows population health professionals to describe the enjoyment that individuals or populations experience and assess how satisfied people are with their health, relationships, activities, and life circumstances (Teoli & Bhardwaj, 2023).
 - **Disability-adjusted life years** (DALYs) help describe the burden of diseases and conditions. This is an important measure, as mortality (death) is not the only negative outcome of ill health. Estimating the number of healthy years lost following premature death and disability associated with a condition provides a

comprehensive understanding of the impact that condition has on the population's health. Over a 16-year period in the United States, adults collectively lost 1.5 million years of healthy life from cancer, chronic obstructive pulmonary disease, congestive heart failure, diabetes, back pain, hypertension, hip fracture, myocardial infarction, arthritis, and stroke (McGrath et al., 2019).

Critical data points or measurements of interest that serve as outcomes for population health depend on the intervention, condition, disease, or health risk that is under study or being addressed. Population health approaches consider the health of a whole population and account for the broad social, environmental, economic, and systems-wide determinants of health. Addressing these broad areas can change the root causes of health problems for a nation or community instead of merely managing the consequences of ill health. Just as risks and negative outcomes can affect individual clients, families, communities, populations, and health systems, the benefits of positive population health outcomes can range from personal to far-reaching. A healthy population may enjoy benefits such as reduced morbidity and mortality, improved quality of life, economic stability, health care cost savings, improved health equity, and resilience to pandemics and other disasters. [The Health of the Population](#) provides more details on methods used to measure population health status.

Focusing on the health of the population and population-level interventions can help improve outcomes across many areas. For example, when diseases are prevented or managed adequately without numerous clinic visits or hospital admissions, both clients and the greater society can save money. In fact, some programs demonstrate cost earnings for every dollar invested in population health initiatives. Beyond preventing overdose deaths, one research team determined that safe injection sites could generate more than four dollars in societal earnings for every dollar invested (Hood et al., 2019). Population health activities can also reduce poverty, increase educational attainment, and improve the economic and social stability of populations. A population-level approach to health presents opportunities to address health inequities and promote social justice. Addressing factors of population health, such as determinants and disparities related to health, promotes health equity across the population.

Population health outcomes can be achieved through both medically focused and social approaches. Medically focused interventions aim to prevent and manage conditions through clinical initiatives and programs in the health care setting. Social interventions address social determinants of health through programming that ameliorates health inequities and creates healthier environments for the population. These two approaches are essential to supporting population health. Several recent examples demonstrate what population health initiatives are and the many ways in which they can benefit society.

Population Health Interventions: Medically Focused

One team of researchers studied population health approaches to improving colorectal cancer screening (Issaka et al., 2019). In 2016, the Community Preventive Services Task Force (CPTSF), part of the U.S. Department of Health and Human Services, recommended increasing the community demand for colorectal screening tests via education and client reminders, increasing community access by offering low-cost and home-based colorectal screening tests, and increasing providers' delivery of such screenings through incentives and reminders (Guide to Community Preventive Services, 2016). Researchers reviewed interventions that aimed to increase colorectal screenings and, following the CPSTF guidance, did not depend on one-on-one client and provider interactions to ensure that interventions could be applied at the population level. The most studied method of increasing screenings among the population, mailing home-based colorectal cancer screening kits to clients, proved most effective. Other interventions that effectively engaged the population in this testing included pre- and post-testing reminders, offering testing during encounters for immunizations, and reminding providers to offer the testing. Population health programs like this one can rapidly improve participation in cancer screenings, reducing rates of advanced or missed cancers across the population as well as inequities in care outcomes that result when cancer is undiagnosed or diagnosed at a late stage. When cancer is identified and addressed early, clients may require fewer medications and surgeries, avoid long hospital stays, and maintain their health, general abilities, and quality of life. Prioritizing population health approaches to promoting cancer screenings is crucial for improving overall health outcomes.

Individuals who experience migraine are another population that has benefited from population health interventions. Migraine is a painful neurological disorder that affects about 15 percent of the global population (Steiner & Stovner, 2023). In addition to pain, migraine leads to missing work and recreational opportunities. A research group developed an occupational health initiative that involved webinars, educational videos, and sharing of web-based migraine resources for employees of a public school district (Burton et al., 2022). Through educating

employees about migraine physiology, triggers, and treatment and ways to self-manage, the initiative enabled the employees to recognize migraine and address their pain more readily. Participating employees talked to their physicians about migraine and took steps to reduce migraine triggers and employ new stress management techniques. This initiative helped empower employees to take proactive steps in managing their health and well-being in the workplace, which can help create a healthier work environment. That the researchers offered the migraine educational program to all of the employees instead of only those who may have self-identified as having migraine reflects the population health goals of ensuring that health resources are broadly available to all members of a population. Finally, by preventing and managing migraine more effectively, employees could miss fewer workdays in the long run. This benefits each employee and their direct work department while reducing the economic burden on the greater population.

THEORY IN ACTION

Total Worker Health®

[Access multimedia content \(<https://openstax.org/books/population-health/pages/1-2-why-population-health-is-important>\)](https://openstax.org/books/population-health/pages/1-2-why-population-health-is-important)

The National Institute for Occupational Safety and Health (NIOSH), a part of the Centers for Disease Control and Prevention (CDC), developed the concept of Total Worker Health®. Total Worker Health® is an approach to promoting the safety, health, and well-being of the working population across all industries by improving factors in and out of the workplace that impact health and population health outcomes.

Watch the video, and then respond to the following questions.

1. How do the principles of Total Worker Health® and population health align?
2. Which determinants of health can affect the health of employees while at work, in the community, and at home?

Population Health Interventions: Social

Population health approaches can address health problems and determinants that extend beyond medical diagnoses. Social interventions encompass a range of approaches aimed at addressing the social determinants of health that have a significant influence on the development or worsening of health conditions. Social interventions can aim to foster inclusive environments, support individuals' financial security, and promote well-being in communities to improve the overall health outcomes of populations.

Some cities in the United States and abroad have trialed universal basic income (UBI) or guaranteed income (GI) programs aimed at one of the key social determinants of health, economic stability. These programs are similar in that they both provide financial support to a population. UBI programs provide all members of a population with the same monthly stipend, regardless of their income, while GI programs provide population members with stipends based on their income and need level. Financial support is provided in the form of immediately accessible cash that recipients may use for any expense as they see fit. The idea behind UBI and GI programs is to help alleviate the consequences of poverty without some of the exclusive features of other public and social assistance programs. For example, in the United States, older adults and individuals with disabilities might receive Social Security payments, but they must qualify based on their age, level of disability, current income, and working status, among other characteristics (Ghuman, 2022). In 2019, the mayor of Stockton, California, implemented a GI pilot program in which 125 city residents with an annual income of \$46,033 or less received \$500 per month. Researchers studied the impact of the GI payments on the residents' health in comparison with residents at the same income level not receiving the payments (Ghuman, 2022). Food was the item recipients used GI funds to purchase most often, followed by merchandise such as clothes and shoes, and then utility bills. Researchers also found that GI fund recipients used the funds to help alleviate financial strain among friends and family in need. Addressing poverty is a complex population health issue, and UBI or GI programs may not ameliorate all the immediate and lasting effects of poverty. However, such programs contribute to broader population health goals and can help people address health needs that would otherwise go unmet due to financial constraints.

Many school-based population health initiatives aim to address the social determinants of health and promote greater health equity. The term *school-to-prison pipeline* refers to disciplinary policies in schools that

disproportionately harm BIPOC (Black, Indigenous, people of color) students by facilitating their entry into the criminal justice system (Aronowitz et al., 2021). Such policies negatively affect population health by impeding school safety, academic success, and school connectedness (Todić et al., 2020). School-based restorative justice programs are one example of how population health can be leveraged to disrupt the school-to-prison pipeline. Restorative justice programs involve “a whole school relational approach to building school climate and addressing student behavior through fostering belonging over exclusion, social engagement over control, and meaningful accountability over punishment” (Armour, 2014). One example of a restorative justice component is offering students peer mediation instead of suspension following a violation of a school rule or the student code of conduct. A 2020 study found that schools that used restorative justice supported the student population in missing fewer school days and achieving higher grades (Todić et al., 2020). Restorative justice programs are one population health approach that can create safe and supportive environments that contribute to health and well-being for school students and the broader school community.

Gay-straight alliances are another example of a school-based population health initiative. LGBTQ+ school students, and subsequently adults, experience many health disparities, including substance use disorders, cardiovascular diseases, cancers, and mental health conditions (Hafeez et al., 2017). LGBTQ+ students are bullied, feel sad or hopeless, and seriously consider suicide at rates that exceed those of their heterosexual and cisgender peers (CDC, 2019). A gay-straight alliance is a club for LGBTQ+ students and allies that can support an inclusive environment in the school and support the mental health of LGBTQ+ students. Researchers used population-level data to determine that gay-straight alliances made school feel like a safer place for LGBTQ+ students and benefited the mental health of students of any sexual orientation or gender (Li et al., 2019). While counseling, therapy, medications, and other interventions can be helpful to students who are bullied or victimized, feel lonely, or express suicidality, prevention and health promotion are key to avoiding these serious health issues altogether. Gay-straight alliances in schools can offer a preventive approach that benefits the entire population of students.

CASE REFLECTION

The Importance of Population Health

Read the scenario, and then respond to the questions that follow.

The Lee family lives in a two-bedroom apartment in a quiet, mostly residential neighborhood within walking distance of a playground complex. Valuing family and education, Alexandra and Christopher usually take the children to the playground at least twice per week and read them books nightly before bed. Although Sunshine loves her school, her parents are considering homeschooling her due to the threat of school-based gun violence. Christopher is unemployed, so he could provide instruction for Sunshine and child care for Woody. The family does not have a car and relies on public transportation to get to work, school, medical appointments, and job interviews. The grocery store is a 15-minute walk from their home, so each adult makes two or three trips to the store per week to manage carrying the grocery bags home. Lately, the family has been eating meals at the two fast-food restaurants in their neighborhood more often due to their convenience and lower cost compared to the grocery store.

1. What are some population health successes that support the health of the Lee family?
2. What are some population health misses that are not supporting the health of the Lee family?

1.3 Population-Based Practice in Nursing

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 1.3.1 Examine the paradigm shift in nursing practice from isolated care to the management of populations across health care systems.
- 1.3.2 Discuss the scope of population health.
- 1.3.3 Examine the competencies that define the knowledge, skills, and attitudes associated with the domain of population health.

Historically, elements within health care and nursing practice have been siloed, or separated and isolated, from one another. This isolation has resulted in specialists and providers of the same or different institutions failing to

communicate with each other effectively or efficiently. For example, suppose Mx. Smith has a primary care provider, diabetes specialist, and heart specialist. The primary care provider and heart specialist may provide care in one hospital, while the diabetes specialist is at a separate clinic. Both the primary care provider and the diabetes specialist may prescribe medications or adjust dosages of the diabetes medications without telling each other of the care plan changes. Mx. Smith may not realize that some prescriptions overlap. Sometimes, providers may initiate a prescription for the same medication using two different brand names, which can lead to unintentional overdosing. Similarly, the primary care provider and the heart specialist could order laboratory testing for the same health problems and might not tell each other that the testing has been ordered and completed. This duplication of care is burdensome to Mx. Smith, who needs to go to a laboratory for bloodwork more than once and pay for testing twice. This lack of communication can be especially dangerous when critical information is not communicated between providers or care facilities (Kelly et al., 2019).

Siloing can also refer to treating one client disease or condition at a time without considering the client's full picture of health, illness, and social situation. When care is siloed, Mx. Smith's heart specialist may make recommendations about heart health that do not consider dietary or activity limitations relevant to the health of their kidneys that the diabetes specialist and primary care provider are working to address. Health systems that are not effectively integrated or properly collaborative make health and illness experiences complex for clients (Storfjell et al., 2017).

While modern health care has not solved the problem of barriers between providers and specialists entirely, a shift to focusing on population health and health promotion has prompted changes in all the health professions in order to reduce such siloing. This paradigm shift has led to more collaborative approaches across health care. Providers and specialists are encouraged to work together to improve client outcomes. Work to reduce silos and focus on population health continues, as some barriers still exist between providers, specialists, and clients. With a continued shift in focus to collaboration, integration, health promotion, preventive services, and population health, providers can work together to deliver comprehensive, holistic, and respectful care to health care consumers.

Delivering Population Health

Moving away from siloed systems is a positive change. In a health care system that has siloed practices, providers react to the presence of symptoms and concerns instead of proactively preventing diseases and promoting wellness. Population-based practices in nursing focus on improving the health of populations through proactive approaches, an emphasis on preventative care, and finding opportunities for early intervention. They focus on effectively managing chronic conditions across the health care continuum—the spectrum of health services that includes public health and preventive care, acute care, ambulatory care, and long-term/chronic care in different settings for members of a population ([Figure 1.6](#)).

- Public health focuses on preventive health measures, health promotion, and population-level health interventions. These measures can prevent disease, reduce the impact of disease, and improve outcomes across a population.
- Acute care involves medical care provided in hospitals and emergency departments for sudden or severe health conditions and emergencies. It can also involve disaster management in events such as multivehicle traffic accidents, train derailments, natural disasters, and mass shootings. Delivery of acute care in a timely and effective manner helps prevent mortality and complications among population members.
- Ambulatory care includes health services provided on an outpatient basis in clinics and health centers. Annual physical exams and health visits related to management of ongoing conditions are examples of ambulatory care encounters. Ambulatory care can respond to population health needs through offering targeted clinics or specialized health services in areas where select conditions are noted to be common or especially burdensome in a population.
- Long-term care services are delivered in skilled nursing facilities, residential facilities, and client homes. People with chronic illness, disability, or functional limitations as well as those receiving palliative care and hospice services obtain support in the long-term care setting. A spectrum of population health outcomes and related goals of care, from minimizing disability to supporting a dignified death, are relevant in this setting. Long-term care can help clients and their families alike. The provision of long-term care supports family members and other familiar caregivers, as some caregiving burdens and stress may be alleviated.

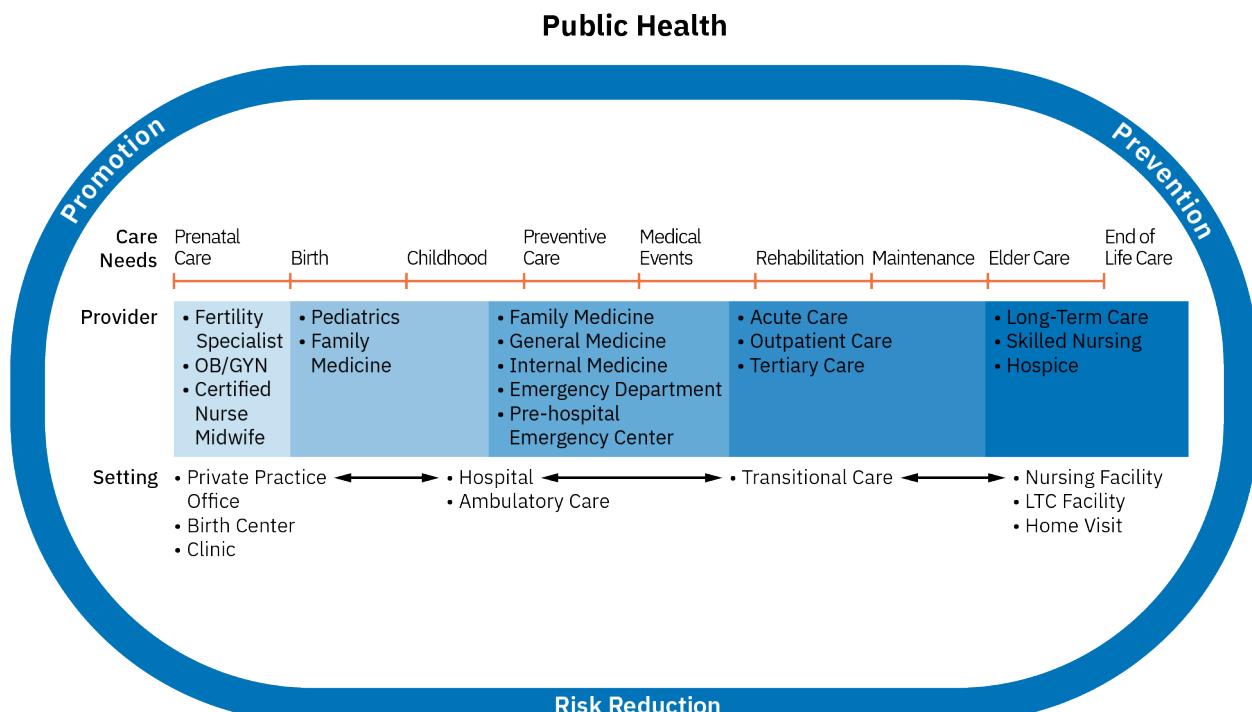

FIGURE 1.6 The health care continuum includes the range of health services that clients will utilize throughout the lifespan. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Thinking about health care as a continuum underscores the idea that health care does not just happen during annual physicals or when someone needs surgery or picks up a new prescription. The concept of the health care continuum affirms that health care services in the public health arena, outpatient settings, hospital units, rehabilitation centers, and family homes are all valid and necessary to population health. On the continuum, health care is comprehensive and coordinated across specialties, providers, facilities, and approaches.

What happens when clients need care in multiple areas along the continuum or move from receiving care in one area to receiving it in another? **Transitional care** involves coordination of clients as they move between care settings. Such coordination helps facilitate a smooth transition for the client or family and helps avoid harm or errors in the process. Transitional care activities may involve sharing of health care information between settings, client education, and support for needed follow-up encounters. These activities help maintain a critical link between settings, providers, and the client so that all may avoid barriers to good health and care delivery. Implementing transitional care across the population helps support healthy client outcomes, reduce health care costs and readmissions, and minimize the likelihood of adverse events during transitions. For example, a research group conducted a review of interventions to support the transition between pediatric health care and adult health care (Schmidt et al., 2020). For adolescents moving to an adult care provider, transitional care support helps achieve outcomes such as decreases in hemoglobin A1C levels (an important measure of diabetes control), increased participation in education and employment, improvements in disease self-management skills, and shorter lengths of hospital stays. The broad goals of population health align with those of transitional care, as professionals in both areas work to improve health outcomes for populations. [Care Transition and Coordination Across the Community](#) discusses this topic in more detail.

CASE REFLECTION

The Care Continuum

Read the scenario, and then respond to the questions that follow.

Alexandra, Sunshine, and Woody receive health insurance through a publicly funded state plan. As the plan only covers pregnant people and children, Christopher currently lacks health insurance. His hypertension is not being treated, and he has not seen a provider in a few years.

Although she has health insurance coverage, as a Black woman, Alexandra is at risk for experiencing adverse pregnancy outcomes due to systemic racism and bias in the health care system. She has had an uncomplicated pregnancy thus far, apart from experiencing frequent viral illnesses due to working in a day care center. She has taken time off to recover from these illnesses and has to take a day off every time she has a prenatal appointment due to the public transportation schedule, so she has missed a great deal of work recently.

1. Which locations across the care continuum is the Lee family currently accessing?
2. What locations across the care continuum would the Lee family benefit from that they are not currently accessing?
3. How could transitional care support help the Lee family?

Nurses drive change in population health through development of innovative programs and initiatives across health care settings. The work of nurses encompasses the entire health care continuum, from prevention to treatment, as well as transitional care to support positive population health outcomes. To recognize the work, leadership, determination, and contributions of nurses who are at the forefront of innovations in population health for clients in hospitals, clinics, residential settings, and communities, the American Academy of Nursing (AAN, 2023) created the [Edge Runners program](https://openstax.org/r/aannetorg) (<https://openstax.org/r/aannetorg>). The AAN annually recognizes nurse-designed models of care that reduce cost, improve care quality, promote health equity, and increase client satisfaction. These projects support moving away from siloed systems in health care and promote population-based practices in nursing. Concepts such as preventive care, early intervention, chronic condition management, and addressing social needs are commonplace among nurse-led population health innovations. As nurses are uniquely positioned to recognize the challenges of navigating several layers of the health care continuum and to address transitional care needs, population health contributions from nurses support client health and optimal population health outcomes. See [Appendix E](#) to learn more about the Edge Runners program.

THE ROLE OF NURSES IN POPULATION HEALTH

[Access multimedia content](https://openstax.org/books/population-health/pages/1-3-population-based-practice-in-nursing) (<https://openstax.org/books/population-health/pages/1-3-population-based-practice-in-nursing>)

This video explores the important role of nurses in population health.

Watch the video, think about the noted “visible” and “invisible” contributions of nurses, and then respond to the questions that follow.

1. How might nurses increase the visibility or public understanding of the “invisible” contributions of population health?
2. What traditionally “invisible” work of nurses might align with your future professional interests?

Population Health Nursing Competencies

Nurses play a crucial role in advancing population health, but they are not alone in this endeavor. Given the importance of a focus on population health and population-based approaches, several leading organizations have developed competencies for trainees and professionals across health disciplines that direct population health education and skills. These initiatives, aim to strengthen the population health competencies of students entering health. For example, the [Public Health Foundation](https://openstax.org/r/phforgPa) (<https://openstax.org/r/phforgPa>) has developed population health competencies to guide workforce development efforts, trainings, program curricula, job descriptions, and other resources to support population health professionals (Public Health Foundation, 2019). Similarly, Duke University developed a competency map that faculty of medical schools, medical residency programs, and physician assistant programs can use to support meaningful integration of population health in education (Kaprielian et al., 2013); these competencies continue to serve as an important framework (Johnson et al., 2020). In 2021, the American Association of Colleges of Nursing (AACN) approved new standards for nursing education, the [Essentials](https://openstax.org/r/aacnnursingo) (<https://openstax.org/r/aacnnursingo>), to define the curricular content and expected competencies of students completing pre-licensure and graduate nursing programs (AACN, 2021). The *Essentials* include a domain focused on population health, as the AACN recognizes the imperative role of nurses in advancing population health.

Some of the competencies related to population health that student nurses are expected to achieve by the time they

finish their pre-licensure program include assessing population health data, identifying ethical principles to protect the health and safety of diverse populations, demonstrating effective collaboration and mutual accountability with relevant parties, proposing modifications to or development of policy based on population findings, and articulating a need for change (AACN, 2021). [Table 1.1](#) lists the population health competencies. These competencies help nursing students prepare to address the health needs of populations once they become licensed as nurses. The content and concepts of this textbook, along with the course instructor's expertise, activities, and assignments, will prepare each student to master the competencies.

Competency	Sub-competency
Manage population health.	<p>Define a target population, including its functional and problem-solving capabilities (anywhere in the continuum of care).</p> <p>Assess population health data.</p> <p>Assess the priorities of the community and/or the affected clinical population.</p> <p>Compare and contrast local, regional, national, and global benchmarks to identify health patterns across populations.</p> <p>Apply an understanding of the public health system and its interfaces with clinical health care in addressing population health needs.</p> <p>Develop an action plan to meet an identified need(s), including evaluation methods.</p> <p>Participate in the implementation of sociocultural and linguistically responsive interventions.</p> <p>Describe general principles and practices for the clinical management of populations across the age continuum.</p> <p>Identify ethical principles to protect the health and safety of diverse populations.</p>
Engage in effective partnerships.	<p>Engage with other health professionals to address population health issues.</p> <p>Demonstrate effective collaboration and mutual accountability with relevant community partners.</p> <p>Use culturally and linguistically responsive communication strategies.</p>
Consider the socioeconomic impact of the delivery of health care.	<p>Describe access and equity implications of proposed intervention(s).</p> <p>Prioritize client-focused and/or community action plans that are safe, effective, and efficient in the context of available resources.</p>
Advance equitable population health policy.	<p>Describe policy development processes.</p> <p>Describe the impact of policies on population outcomes, including social justice and health equity.</p> <p>Identify best evidence to support policy development.</p> <p>Propose modifications to or development of policy based on population findings.</p> <p>Develop an awareness of the interconnectedness of population health across borders.</p>
Demonstrate advocacy strategies	<p>Articulate a need for change.</p> <p>Describe the intent of the proposed change.</p> <p>Define interested parties (stakeholders), including members of the community and/or clinical populations, and their level of influence.</p> <p>Implement messaging strategies appropriate to audience and other interested parties.</p> <p>Evaluate the effectiveness of advocacy actions.</p>

TABLE 1.1 The Essentials: Population Health Competencies and Sub-competencies (adapted from AACN, 2021)

Competency	Sub-competency
Advance preparedness to protect population health during disasters and public health emergencies.	Identify changes in conditions that might indicate a disaster or public health emergency.
	Understand the impact of climate change on environmental and population health.
	Describe the health and safety hazards of disasters and public health emergencies.
	Describe the overarching principles and methods regarding personal safety measures, including personal protective equipment (PPE).
	Implement infection control measures and proper use of personal protective equipment.

TABLE 1.1 The Essentials: Population Health Competencies and Sub-competencies (adapted from AACN, 2021)

A focus on population health in a nursing program or a practicing nurse's work does not mean ignoring or no longer managing acute needs. While a shift to a population health paradigm supports the work of nurses in multiple settings, these competencies apply to nurses working in acute or tertiary care settings as well. For example, nurses working in emergency care provide lifesaving interventions, but they can also recognize and address the upstream, population, and system-wide factors that lead clients to require emergency care (Fawcett & Ellenbecker, 2015). Population health competencies allow a nurse to be well-versed in and ready to address the complex needs of clients so they may provide more effective and comprehensive care. The focus on population health within nursing programs and nursing as a broad discipline does not mean that acute or emergent health needs are no longer important. Adopting a population health framework builds on the work of nurses and expands their impact in all settings. The *Essentials* and their competencies are relevant to the work of nurses across the care continuum, and ensuring that nurses of the future frame their practice through a population health lens helps them address the complex needs and conditions of clients today.

CASE REFLECTION

Population-Based Practice

Read the scenario, and then respond to the questions that follow.

The Lee family's city has been experiencing a drinking water crisis for several years. Alexandra or Christopher must go to a city building once per week to obtain drinking water for the family. The family is also supposed to bathe in this water, but the city does not provide enough water for drinking, cooking, and bathing.

1. What are some population health concepts or components that are relevant to this problem?
2. Which of the population health competencies or sub-competencies specific to this problem could a nurse demonstrate to support the Lee family?

Chapter Summary

1.1 Defining Population Health

Population health is a comprehensive approach that considers the impact of various factors on health and involves collaborative efforts among health care professionals, communities, industries, academia, and governmental organizations. Nurses across all settings and specialties are critical advocates for achieving population health goals. Population health takes a proactive approach to addressing the root causes of health problems as a means of prevention. Critical components of public health include outcomes, determinants, disparities, and risk factors. Concepts of upstream, midstream, and downstream approaches to intervention interact and evolve as population health evolves, with upstream interventions offering the widest-reaching health benefits to the population. Population health extends to the global stage, involving global nursing, which aims to promote sustainable planetary health and equity for all individuals.

1.2 Why Population Health Is Important

Promoting health across a population is essential for improving health outcomes for individuals and society. Rather than treating individual illnesses as they arise, population health approaches aim to prevent

Key Terms

- determinants** factors that influence health; can include events, characteristics, or other entities that change a health condition or the level of a health problem
- disability-adjusted life years (DALYs)** estimates the number of healthy years lost across the population due to premature death and disability from a select condition
- disparities** inequalities or differences
- downstream** describes interventions that focus on the behavior of individuals to modify the risk of disease, prevent illness, or manage chronic conditions
- general mortality** the number of deaths across a large population, such as a geographic region or country, reports of which include information about leading causes of death across the population and estimates of years of potential life lost when people die prematurely
- global nursing** the use of evidence-based nursing processes to promote sustainable planetary health and equity for all people
- health care continuum** the spectrum of health care services delivered in public health, acute care,

conditions and manage diseases more effectively when they occur. National health indicators provide a macro-level perspective of a nation's health status, contributing to a comprehensive understanding of population health. Population health approaches improve cost savings, actualize social benefits, promote equity, facilitate social justice, and improve health outcomes.

1.3 Population-Based Practice in Nursing

A shift toward population health and health promotion in nursing has encouraged collaboration and meaningful integration of systems across the health system. Emphasizing preventive care, early intervention, and chronic disease management is a positive change under a population health paradigm within the entire health care continuum, which includes preventive care, acute care, long-term care, and transitional care. Nurses are driving change in population health and have developed many innovative, proactive care programs. Today, student nurses are expected to achieve competencies relevant to providing care at the population level and leading change that ameliorates upstream factors contributing to poor health outcomes in the United States.

ambulatory care, and long-term care settings

health care utilization the extent to which a population accesses and uses different health care services

health inequities avoidable inequalities related to health that stem from a form of injustice

infant mortality the rate of infants who die before their first birthday

life expectancy the average number of years a newborn is expected to live if current death rates remain constant

midstream describes interventions that occur within a specific organization

morbidity rate the prevalence or incidence of a specific health condition, disease, or diagnosis within the population

outcomes in a population health context, all possible results that may come from exposure to interventions aiming to prevent or treat a condition

population a group of people that may receive care in various settings at the local, regional, national, and global levels

population health an approach to supporting the health of people through research, data analysis,

and health programming that considers the impact of public policy and environmental, social, behavioral, and other factors that might facilitate or hinder health for all

quality of life indication of enjoyment and satisfaction people have, given their multidimensional experiences in health, relationships, activities, and life circumstances

risk factors aspects of personal behaviors, lifestyle choices, exposures, or attributes that generally increase the likelihood or severity of acquiring a

health condition

social determinants of health conditions and social factors that affect outcomes and risk related to health, functioning, and quality of life

transitional care efforts aimed at coordinating health care as clients receive services in various areas of the health care continuum

upstream describes interventions that involve enacting policies that change regulations, increase access, or provide economic incentives to impact health across a population

Review Questions

1. Which activity would the nurse perform when engaged in population health activities?
 - a. Treating an individual for a specific disease
 - b. Improving health outcomes for groups of people
 - c. Evaluating a family's ability to care for a child with diabetes
 - d. Teaching a client health promotion behaviors

2. Which method would the nurse utilize when taking an individual-level approach to smoking cessation?
 - a. Forming a smoking cessation support group
 - b. Promoting an increase on taxes on the purchase of tobacco
 - c. Providing nicotine gum to a client to substitute for an inhaled tobacco product
 - d. Researching the reasons for initiation of tobacco use

3. Which central tenet of population health should the nurse include when planning population health priorities?
 - a. Proactively promoting health among populations
 - b. Reactively managing health conditions
 - c. Treating diseases in individual people
 - d. Focusing on increasing the number of hospitals

4. Which action by the nurse represents a midstream approach to improving population health outcomes?
 - a. Advocating for policy changes regarding fast food
 - b. Providing a workplace lunchtime walking program
 - c. Encouraging a client to lose weight
 - d. Starting a support group for smoking cessation

5. Which action by the nurse promotes population health?
 - a. Providing treatment for chronic disease
 - b. Conducting health education workshops
 - c. Offering individual health consultations
 - d. Administering medication for acute illnesses

6. Which data should the nurse utilize to determine the leading cause of death across the population?
 - a. Infant mortality
 - b. Life expectancy
 - c. Morbidity rate
 - d. General mortality

7. Which potential barrier of siloed health care should the nurse consider when planning health promotion activities?
 - a. Providers and specialists working closely together to improve outcomes
 - b. Treating one disease at a time without evaluating or addressing the full picture of health

- c. Health systems becoming effectively integrated
 - d. An emphasis on population health and health promotion
- 8.** Which action is a characteristic of population-based nursing practice?
- a. Taking a proactive approach to promoting wellness and preventing disease
 - b. Emphasizing curative care rather than preventive care
 - c. Focusing on reactive approaches to managing acute illnesses
 - d. Providing care only outside of hospital settings
- 9.** Which concept should the nurse utilize when planning transitional care for a population?
- a. Providing care in multiple areas of the care continuum to address all client needs
 - b. Reactively managing health conditions during transitions between health care sites
 - c. Preventing hospital readmissions and adverse events
 - d. Coordinating clients as they move between care settings
- 10.** Which health service along the health care continuum would the nurse utilize for a client with health care needs related to a chronic condition?
- a. A preventive health program
 - b. An ambulatory care clinic
 - c. An acute care department
 - d. A long-term care facility

CHAPTER 2

Foundations of Public/Community Health

FIGURE 2.1 Increasing access to dental care is essential to maintaining good oral health, which is a crucial aspect of overall health and well-being. Support for mobile health units aligns with population health goals to achieve health equity and address social determinants of health. Follow [this link](https://openstax.org/r/manchesternhaaaa) (<https://openstax.org/r/manchesternhaaaa>) to read about the Manchester, New Hampshire, mobile dental program for schoolchildren. CHAPTER OUTLINE

- 2.1 Defining Public Health
 - 2.2 Historical Perspectives on Public/Community Health
 - 2.3 The Importance of Public/Community Health
 - 2.4 The Core Functions and Essential Services of Public Health
 - 2.5 Levels of Prevention
-

INTRODUCTION Whether or not a public health department formally employs them, all nurses support public health in some capacity. Nurses working in specific public health roles may lead disease surveillance and investigations, promote health, and provide community education or perhaps develop health policy. Nurses working in schools, clinics, hospitals, colleges, private industry, or any other role impact public health by fulfilling their duty to promote and protect the population's health and well-being.

Public health is a distinct discipline that operates alongside and in support of nursing. Nursing and public health have overlapping areas of focus and collaboration. Similarly, public health and community health are two fields that operate in concert to improve population health. This chapter and the next will use the term “public/community health” because these closely related disciplines and concepts are interconnected in their goals and functions. In fact, in nursing, community health has long been viewed as indistinguishable from public health (American Nurses Association [ANA], 2022, p.3). However, it is important to acknowledge some of the differences between public and community health that members of health care disciplines may recognize:

- **Public health:** Health care professionals use research involving many people and large data sets to create policies and interventions meant to improve health. Public health efforts may target large populations or global concerns and can have far-reaching, long-term impacts on health. Generally, public health efforts prevent disease, promote and disseminate health interventions, and protect people from timely health threats such as pandemics, violence, climate change and environmental hazards, and substance misuse, to name a few.
- **Community health:** Health care professionals use research and data to inform their work, but they also work closely with community partners and local clients/families to understand health priorities and contextual factors specific to the community. Community health efforts focus on the health and risks of a specific locality or group of people and therefore usually have a more immediate impact on the community. In community health, the health status, health needs, resources, circumstances, and other factors specific to communities of people guide work aimed at supporting the health of individuals, families, groups, and organizations.

This chapter explores the goals and functions of public health, while [Public/Community Health in Practice](#) discusses the roles and responsibilities of public health nurses. As you read this chapter, think about Alexandra Lee, a daycare teacher expecting a baby, and her family, who were introduced in [What Is Population Health?](#). The Lee family also includes Alexandra's husband, Christopher, who is currently unemployed and has hypertension; Sunshine, a kindergarten student with life-threatening allergies; and Woody, a generally healthy toddler. Chapters 1, 2, and 3 will follow the Lee family to explore how population, public, and community health impact their well-being.

2.1 Defining Public Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 2.1.1 Define public health.
- 2.1.2 Differentiate between upstream and downstream encounters.
- 2.1.3 Contrast public health with population health.

Public health supports the well-being of society through organized efforts to ensure health is attainable for all. It extends beyond nursing, although principles of public health provide the foundation or framework for public/community health nursing practice. Nurses and other public health professionals work to prevent health problems by implementing educational programs, recommending policies, administering services, conducting research, and limiting health disparities (CDC Foundation, 2023). To that end, public health efforts usually involve developing, implementing, evaluating, and revising policies and programs. Policies and programs can also contribute to controlling the spread or incidence of diseases and disorders, reduce rates of injury, and lessen disability or its impact on populations. Public health policies and programs are designed to promote health, prevent disease and injury, prolong life, support quality of life, and reduce health disparities. Ultimately, public health work ensures that populations can live in conditions where health is achievable (American Public Health Association [APHA], 2022).

This textbook discusses population, public, and community health mostly in the context of the United States. The health care systems in different nations and societies are markedly different. Despite different infrastructure, policies, and national views on health as a priority, nurses know that communities across the globe have a right to be healthy. To that end, nurses, clinicians, and others involved in public/community health may be involved in global health work. [Global health \(<https://openstax.org/r/healthgovhealthaa>\)](https://openstax.org/r/healthgovhealthaa) initiatives can address many pressing health areas, but the goal of such efforts is to improve health by preventing, detecting, and responding to public health events across the world (Office of Disease Prevention and Health Promotion [ODPHP], n.d.).

The world population exceeds eight billion people. Evaluating the health and health risks of all people is a significant undertaking, let alone actually addressing the health and health risks of such a large and diverse group. Health problems of the global community are not necessarily novel to those experienced by Americans; issues of communicable (e.g., tuberculosis) and noncommunicable (e.g., heart disease) diseases, access to water and nutrient-dense foods, safe housing, and gender equity transcend borders. It is critical to acknowledge that involvement of the U.S. government and American clinicians in global health initiatives can carry harm. Sometimes, support from one country to a developing nation to address a public health issue can carry colonial and paternalistic undertones. **Colonialism** refers to the practice of a powerful nation asserting control and exploiting another nation for political or economic purposes. **Paternalism** involves authority figures making decisions for others in a manner

that suppresses their identity and autonomy. Both colonialism and paternalism have been historically implemented in global health initiatives as well as one-to-one clinical care.

Health interventions and programming may be motivated by the values and priorities of more-developed nations without consulting local communities and partners to ensure which health issues need to be addressed and how. For example, sometimes health education materials made in the United States for American health care consumers are delivered abroad. Health education materials for managing hypertension might include messages such as “participate in physical activity” and “avoid processed salty foods like hot dogs.” Materials delivered to a developing nation with limited access to processed foods, where most people have never eaten hot dogs and travel exclusively by foot, would not help educate community members about their specific risks for hypertension and would not offer reasonable solutions given the community context. This dynamic can disincentivize the involvement of communities, undermine their autonomy, and ultimately lead to harm. A global health arrangement that does not adequately involve local community members through problem identification, assessment, intervention planning, and implementation also leads to mistrust of global health programs (Gautier et al., 2022). Nurses in public/community health must work to foster genuine partnerships and consult local community members when supporting health abroad to have a positive impact and uphold health as a right for all. This is also true of local health initiatives: Nurses must involve community members to avoid paternalistic approaches. Future chapters will share strategies for meaningfully engaging community members in public health work.

Impact of Global Health on Domestic Wellness

Global health concerns, such as infectious diseases (e.g., pandemics like COVID-19), can directly affect the health of individuals in the United States, and public/community health nurses play a crucial role in addressing these influences. Global health crises, such as outbreaks or natural disasters in other countries, serve as lessons for improving emergency preparedness in the United States. Public health nurses contribute to domestic preparedness efforts by drawing insights from global experiences. Public health nurses are involved in surveillance efforts, monitoring international health trends, and helping identify potential threats. They play a key role in preparing for and responding to global health crises by ensuring effective disease control measures.

Immigration and refugee flows from around the world directly impact the health of communities in the United States. Public health nurses work to address the unique health needs of immigrant and refugee populations, including vaccinations, access to health care, and culturally sensitive care. Public health nurses engage in global health policy discussions and advocacy efforts. They work with international organizations, governmental agencies, and nongovernmental organizations to shape policies that influence global health and, in turn, have consequences for domestic health. They advocate for global health equity and apply principles of equity in their local practice, recognizing the interconnectedness of health issues across borders.

THEORY IN ACTION

What Is Public Health?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/2-1-defining-public-health>\)](https://openstax.org/books/population-health/pages/2-1-defining-public-health)

In this video, members of the American Public Health Association (APHA) discuss public health and some current examples of public health initiatives.

Watch the video, and then respond to the following questions.

1. The narrator, Dr. Georges Benjamin, states that “only a small amount of what affects our health actually happens in the doctor’s office.” Think about the community, town, or city of your nursing school. What factors, outside of care at a hospital or clinic, are most impactful to the health of area residents?
2. APHA members provide examples of their work that contribute to public health. Which of the examples has impacted the health of you and your classmates over the last year?

Upstream and Downstream Encounters in Public Health

The causes of health problems are generally viewed through two lenses: 1) system or society-wide problems that precipitate unhealthy circumstances or 2) individual choices that lead to illness and disease. Responses to health

problems are, by definition, reactive—meaning a client must have a disease or condition before a clinician provides a prescription or a client engages in a healthy habit to cure or lessen its impact. Consider seasonal influenza (flu). A lack of paid sick time from work is a society-wide problem contributing to the spread of the flu, as clients will go to work sick and spread a virus rather than miss a day of pay. The client may interact with other people who have seasonal flu and do not practice good cough and sneeze hygiene. Once the client starts to feel ill or seeks care, depending on how early they contact a health care provider, they may receive a prescription for an antiviral medication to lessen the duration of their bothersome symptoms.

Consider the metaphor of “upstream-downstream” health factors (Dorfman & Krasnow, 2014; see [What Is Population Health?](#) for more information). Dr. John McKinlay introduced the metaphor to the medical community in 1975, defining downstream endeavors as responses to shifts from one health issue to the next, focusing on the short-term that does not solve any health problems (McKinlay, 2019). He argued that the health care community should focus on upstream work—that is, the sources of health problems or manufacturers of illness. Explained differently, downstream health initiatives are reactive actions taken to address the symptoms or consequences of diseases, while upstream initiatives address the root causes of health issues. Downstream interventions for the client with seasonal flu include providing recommendations for rest, hydration, and perhaps an antiviral prescription, plus a reminder to practice good handwashing and cough and sneeze into the elbow instead of the hands. Upstream interventions might involve community-wide messaging on the same healthy habits and the development of policies that support public health through offering compensated sick time so that clients do not need to decide between their health and the health of their colleagues and a much-needed paycheck.

Every client or health condition has upstream and downstream factors preceding diagnoses or preventing conditions. For example, diabetes is known to affect clients living in low-income neighborhoods (Hill-Briggs et al., 2021), and the percentage difference in diabetes rates for poor individuals (living 100 percent or more below the federal poverty level) compared to wealthy people is over 100 percent (Beckles & Chou, 2016). A downstream intervention for a client with type 2 diabetes mellitus may be the administration of metformin, insulin, or other anti-diabetic agents. But what about the neighborhood? Nothing in this intervention addresses how living in a low-income neighborhood precipitates diabetes. Upstream interventions address the community conditions and circumstances that impact health. Upstream interventions for those living in a low-income neighborhood might include supporting the availability of fresh produce over packaged or canned choices, funding a free community fitness center, or maintaining sidewalks for outdoor exercise for clients with and without mobility aids.

As another example, hypertension is more prevalent among Black adults than White adults (Centers for Disease Control and Prevention (CDC), 2023c; Huang et al., 2022). A downstream intervention for a client with hypertension may involve prescribing lisinopril (a medication used to treat high blood pressure) and quarterly clinic visits to monitor blood pressure. However, these sample interventions include nothing about a person’s race placing them at higher risk of hypertension. In fact, considering a client’s race, which is a social construct, in place of *biology and genetics*, is an unfavorable practice that contributes to disparities and harm (American Academy of Family Physicians, 2020). An upstream intervention related to hypertension might address institutional racism that leads to stress among people of color and fewer social, health, and economic opportunities across communities of color.

THE ROOTS OF HEALTH INEQUITIES

Racism and Cardiovascular Health in Black Moms

Pregnant clients are at risk for hypertensive disorders of pregnancy, including gestational hypertension, preeclampsia, and eclampsia. These disorders place the pregnant person and fetus at risk during gestation and impact both parties after birth. African, Caribbean, and Black women are more likely to experience hypertensive disorders of pregnancy, and they remain at risk for acute and chronic cardiovascular disorders for life. Racism is one modifiable factor that increases the risk of hypertensive disorders of pregnancy among Black mothers. It can contribute to daily stress, which compounds the physiologic stress that pregnancy places on the cardiovascular system. Experiences of racism in the medical setting may lead to missed health care appointments, decreasing opportunities to identify hypertensive disorders of pregnancy early and initiate treatment. While this is not a uniquely American problem, Black women born abroad have lower rates of hypertensive disorders of pregnancy than Black women born in America. While nurses and other clinicians need to provide personalized, attentive,

and respectful health care services to Black mothers, upstream education and policy-related factors must change to adequately address this avoidable health problem. Clinician education must be developed and implemented with an anti-racist framework. Clinicians and researchers need to promote the ideas, experiences, and opinions of Black mothers when conducting studies and developing policy and meaningfully involve them on teams working to address this health issue.

(See Baiden et al., 2022.)

CASE REFLECTION

Addressing Upstream and Downstream Factors

Read the scenario, and then respond to the questions that follow.

You are continuing to work with the Lee family. Think about their current health state or diagnoses:

- Alexandra, pregnancy: 37-year-old daycare teacher, works 5 days a week from 8 a.m. to 4:30 p.m. She wakes up early to prepare breakfast for her family and then commutes to work via public transportation. She is currently 30 weeks pregnant. Thus far, she and her care team have been pleased with her blood pressure readings. Still, she has found it challenging to keep her stress low as her husband Christopher recently lost his job, and few employers are hiring. As a Black woman, Alexandra is at risk for experiencing adverse pregnancy outcomes due to systemic racism and bias in the health care system.
 - Christopher, hypertension: Although he has not attended a health check-up in a few years, he feels that his blood pressure might be higher since losing his job. Being unemployed has been stressful, but as a Korean American, he experienced a great deal of anti-Asian sentiment and discrimination from his coworkers during the COVID-19 pandemic.
 - Sunshine, life-threatening allergy: Sunshine just started kindergarten and has an epi-pen for a life-threatening nut allergy. She was attending an after-school arts and crafts program two days per week but stopped going when Christopher lost his job.
 - Woody, generally healthy.
1. What upstream factors may negatively affect Alexandra's pregnancy experience and outcome? What changes to upstream factors might improve her health and lower health risks?
 2. What are some upstream factors contributing to or worsening Christopher's hypertension? What changes to upstream factors may have prevented or could contribute to ameliorating his hypertension?
 3. Are there any upstream factors that can impact how Sunshine's life-threatening allergy is managed? Think about anaphylactic reactions that may occur at home, at school, or in the community.
 4. What are some downstream factors the family is currently engaged in? Without changes to upstream factors, what additional downstream factors are needed? Which downstream factors would be obsolete with changes to the upstream factors?

Although upstream work can benefit individuals and populations, a great deal of work in health care is still taking place at the downstream level. The biomedical model of *treating* individuals and individual health conditions following diagnosis persists instead of focusing on *preventive* efforts that would improve the prevalence and severity of risk factors for the health conditions (Dopp & Lantz, 2020). A barrier to upstream work may be the scope of upstream issues and collective, systems-wide changes that must be made to properly address them. The upstream social structure factors include the economy, poverty, education, cultural values, discrimination and privilege systems, food, housing, criminal justice systems, and public policy (Dopp & Lantz, 2020). Due to the far-reaching impacts of disparities, injustices, and other experiences not aligned with health in these upstream factors, seemingly tiny steps toward improvement matter. Researchers have noted that even small changes in upstream factors result in greater improvements in health than downstream initiatives (Dopp & Lantz, 2020).

THEORY IN ACTION

What Is Public Health?: Episode 1 of “That’s Public Health”

[Access multimedia content \(<https://openstax.org/books/population-health/pages/2-1-defining-public-health>\)](https://openstax.org/books/population-health/pages/2-1-defining-public-health)

Mighty Fine of the American Public Health Association discusses public health in this short video. He discusses public health and the emphasis on upstream factors.

Watch the video, and then respond to the following questions.

1. Downstream measures related to tobacco use, like taxes on cigarettes and images of diseased organs on packaging, have not changed tobacco use as a leading cause of death. What do you think of the upstream interventions suggested by the narrator? What other upstream ideas can you think of?
2. Mr. Fine also mentions that public health efforts can look like creating parks or repairing sidewalks. These are two upstream factors that are not obviously related to health. Can you think of programs in your community that might not look like health interventions but are actually public health upstream initiatives?

How Public Health Differs from Population Health

Both population health and public health aim to improve the health of populations. Both can optimize health care delivery and improve outcomes across the population. Both are essential in addressing the complex, interrelated, and intersectional factors that influence health in the modern world. Key differences between population health and public health are the ways in which the health of a population is changed, the focus, and the scope of work.

Population health

- focuses on the actions and initiatives of a health system and what is being done for a community (Bharel & Seth Mohta, 2020);
- carefully considers and emphasizes determinants of health, such as those in the environmental, social, economic, and educational domains, to achieve better health outcomes for the population; and
- assesses the health status of a population, identifies unique health challenges, and designs interventions to address the challenges.

Public health

- undertakes collective actions throughout society to ensure the conditions necessary for clients to maintain good health (Institute of Medicine (US) Committee on Assuring the Health of the Public in the 21st Century, 2002);
- organizes efforts in public policy, governance, and health services to protect and advance the health of the population; and
- implements strategies and interventions (e.g., policies, regulations, and guidelines) at a societal level to support favorable health conditions for all.

Considering the diabetes and hypertension examples discussed earlier with upstream and downstream factors, each has population and public health aspects. For the client with type 2 diabetes mellitus, living in a low-income neighborhood is a population health factor influencing the availability of fresh produce and nutrient-dense foods and having space to enjoy physical activity. If the city where the client resides approves a regulation that sets tax-generated public funds aside to repair sidewalks or build a free community fitness center, this would be a policy-related public health intervention. For the client with hypertension, racism and the accompanying injustices are a population health factor affecting the client's blood pressure. Many public health policies addressing institutional racism and health equity can ameliorate the impact of racism on cardiovascular health. For example, experts have recommended public health policies such as improving state-level race and ethnicity data collection, ensuring provider training to reduce bias and discrimination in health care, and increasing workforce diversity to address the upstream causes of racism in cardiovascular medicine (Javed et al., 2022).

2.2 Historical Perspectives on Public/Community Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 2.2.1 Describe historical factors relevant to shaping public/community health practice.
- 2.2.2 Discuss the textile industry as an exemplar for understanding historical and contemporary implications of public health.

Events throughout history have played a pivotal role in inspiring, shaping, and advancing the public health field. Several noteworthy accomplishments, such as the development of vaccines, sanitation and waste management reforms, the formation of public health departments, and the introduction of health plan mandates, have significantly influenced the public's health and the trajectory of public health as a specialty. The field of public health has evolved over time and has a longstanding history in the United States. In fact, as the nation formed during the American Revolution, the new nation's leaders believed that human health was supported by strong social institutions, and this view was fundamental to creating the American political structure (Rosen, 1976).

Approximately 100 years after the American Revolution, Louisiana and Massachusetts led a revolution in public health programs (Levine & Rosencrantz, 1972). Louisiana created a Bureau of Statistics and Board of Health in 1849 and 1855, respectively, with an advisory capacity. In 1869, Massachusetts became the first state to develop a State Board of Health with the power to enforce regulations to prevent deaths attributable to disease spread via unsanitary conditions. Around the same time, germ theory revolutionized approaches to public sanitation, personal hygiene, surgical practices, vaccination, and epidemiology (King, 1983; Tulchinsky & Varavikova, 2014). In the early 1900s, journalistic inquiry and publicization of unhealthy practices throughout industries (e.g., Upton Sinclair's novel, *The Jungle*, which was based on true events confirmed via investigation) led to calls for increased health regulations (Kantor, 1976). To learn about other notable events that have shaped population, public, and community health, see [Epidemiology for Informing Population/Community Health Decisions](#) and [Pandemics and Infectious Disease Outbreaks](#).

The Industrial Revolution and the Development of the Modern Public Health System

Comparing health and safety during the Industrial Revolution to contemporary industrial practices provides insights into the similarities, challenges, and opportunities in the public health realm of yesterday and today. A global Industrial Revolution started during the late 1700s. During this time, producing goods and products moved from slow, labor-intensive, manual processes to those that could become more efficient and, at times, automated with the use of new machines. Using steam and water to power machines also emerged during this time, and using large factory systems in manufacturing was adopted.

Business and factory owners wanted to quickly create more products, such as textiles, to sell to the expanding population. Profits on textiles were higher than ever following industrialization and cheap labor (Library of Congress, n.d.). While this period may have been exciting for urbanization, technology, and businesspeople who owned the means of production, it was a dangerous time for laborers. Rapid industrialization and urbanization led to poor sanitation, overcrowding, and disease outbreaks, prompting the need for attention to the public's health and formation of public health infrastructure. By the early 1800s, Francis Cabot Lowell brought textile technologies to eastern Massachusetts, where he initially employed young women from nearby rural communities who would work for lower wages than men. By the 1860s, more than half the workers were immigrants (American Social History Project, n.d.). The workers were required to work long hours without breaks in factory rooms with poor air quality and no ventilation and to live in quarters with doors that were locked overnight (Bartlett, 1841; Beaudry & Mrozowski, 1989; Murphy et al., 2019). They were required to rent rooms in factory-owned housing with similarly unsafe and unsanitary conditions (Bartlett, 1841; Britannica Editors, 2023). These working and living conditions led to injuries, croup, lung inflammation, bleeding lungs, cholera, scarlet fever, measles, dysentery, and brain inflammation among the workers (Crane-Kramer & Buckberry, 2023; Murphy et al., 2019; Robinson, 2011). Additionally, the accelerated decline of environmental air quality from factory emissions complicated respiratory conditions (Fowler et al., 2020). Of 362 recorded deaths in the Lowell mills, 200 were girls under the age of 10 years (Murphy et al., 2019; Robinson, 2011).

Sanitation and worker safety reforms were implemented, and public health departments were established at local and state levels following global experiences that were similar to those of the mill workers of Lowell (Hanlon &

Pickett, 1984). Workers and other concerned parties did not necessarily know the cause of their ill health, but collective social actions helped advance public health ([Figure 2.2](#)). The reforms are not considered healthy (or legal) by today's standards, but they represent progress in public health. For example, regulations were put in place permitting only children over the age of 9 to work and for no more than 9 hours per day (Teleky, 2012). The environmental conditions also prompted a collective call for public health measures. Beyond acquiring illness and disease from issues with the disposal of bodily fluids and overcrowding, factory workers and citizens alike were motivated to create change in workplace and community sanitation due to unpleasant smells (Shryock, 1937). Reform movements concerning child labor, working conditions, the environment, and overcrowding of cities led to implementation of policies and regulations to protect the public's health.

This period in U.S. history and the efforts of workers to reform practices are credited with establishing the modern public health system. In fact, the Industrial Revolution period is referred to as "the great sanitary awakening" (Winslow, 1924). A societal objective of promoting cleanliness elevated health to priority status, resulting in collective efforts to protect health among the public (Institute of Medicine Committee for the Study of the Future of Public Health, 1988). During this time, the collection of public health data and vital statistics began paving the way for statistics to become a fundamental piece of public health work (Rosenkrantz, 1972).

FIGURE 2.2 Factory workers sew garments in the 1940s. Even after the Industrial Revolution, the workforce of garment workers was comprised largely of women who did tedious work in ergonomically unfriendly conditions at best. Windows in this factory are pictured as opened, which greatly improved spread and inhalation of dust, viruses, and other airborne health threats. (credit: "Women sewing at long tables next to tall windows in a garment factory" by Kheel Center/Flickr, CC BY 2.0)

Public Health in the United States from the 20th Century to the Present

Today, working conditions across industries are more regulated to support health. In the United States, public health policies regarding sanitation and air quality have advanced greatly since the Industrial Revolution. Government bodies, such as the U.S. Environmental Protection Agency (EPA), support public health through policies and regulations that enforce healthy air indoors. Pollutants such as carbon monoxide, mold, lead, asbestos, and pesticides can affect the health of workers and residents (EPA, 2023). The EPA recognizes health impacts such as eye irritation, headaches, respiratory disease, chronic conditions, and even a condition called sick building syndrome in which building occupants feel ill after entering a certain building and feel better once leaving (EPA, 2023).

While the post-Industrial Revolution establishment of national organizations focused on environmental health represented an improvement, experts argue that the EPA does not adequately protect people vulnerable to environmental health threats (Koman et al., 2019). Similarly, the working conditions of modern garment workers, both domestically and abroad, do not always support health ([Figure 2.3](#)). This has left some to question if public

health has made an impact since the Industrial Revolution and how public health can support health in this area. Although they have improved since the Industrial Revolution, public health policies and initiatives in the United States are either underdeveloped or under-enforced and do not protect all workers. For example, the report [*Dirty Threads, Dangerous Factories*](https://openstax.org/r/garmentworkerce) (Garment Worker Center et al., 2016) identifies several unsafe and unhealthy conditions for garment workers in Los Angeles, California, such as:

- 60 percent of workers noted that excessive heat and dust accumulation in garment factories made it difficult to work and breathe;
- 47 percent of workers reported soiled and unmaintained bathroom facilities;
- 42 percent of workers stated that exits and doors in the factories were regularly blocked; and
- 89 percent of workers reported an injury to their employer, over half of whom had a negative reaction to their report of an injury.

Further, some public policies regarding working conditions are being revised to be unsupportive of public health. Federally, labor laws prohibit children under the age of 14 from working during certain hours or too many hours per week except for children working in agriculture (U.S. Department of Labor, 2023). Mid-2023 saw some states, such as Missouri and Iowa, approve public policies that permitted children aged 14 to 17 years to work more hours per week in an expanded group of possibly dangerous industries with less safety oversight (Bogage, 2023; Figueroa, 2023). The work of public health as a discipline is never truly complete, as consistent evaluation of the actual implementation and outcomes of policies and programs is needed as societal conditions evolve.

Despite ongoing challenges in areas such as worker safety, the population's health has largely improved thanks to public health initiatives. Public health efforts have contributed to advances in life expectancy, health promotion, and disease prevention and have reduced mortality rates. However, health disparities, inequities, and injustices still exist. Public health efforts must be supported to address health issues and improve the population's health.

FIGURE 2.3 This image reveals a large factory workspace with adult-appearing workers. While clean floors and glimpses of natural light create an initial positive impression, gauging the overall workplace health proves challenging. Notably, photos distributed to the public may be taken during official state/government visits. During planned visits, manufacturing facilities are often meticulously cleaned or staged to shield government officials and guests from witnessing unfavorable aspects such as child labor, forced labor, or unhealthy conditions. Unfortunately, this practice persists both domestically and abroad, where laborers work long hours for little pay and endure exposure to harmful chemicals; learn more by reading the following [news story](https://openstax.org/r/nprorg). Nursing work relevant to public health, population health, global health, occupational health, maternal/child health, and other areas all intersect when working to address health in the textile industry. (credit: "President Tsai visits Taiwanese firm Roo Hsing Garment (Nicaragua) and learns about the factory's operation" by Taiwan Presidential Office/Flickr, CC BY 2.0)

Contemporary Public/Community Health Emergencies

Worker health and environmental protection are only two of many enduring public/community health challenges that nurses and other professionals work to address today. The most pressing contemporary public/community health issues may rise to the level of national or local emergency. In the United States, the secretary of the U.S. Department of Health and Human Services (HHS) or the president may declare federal **public health emergencies**, while state- or local-level officials like governors, mayors, and tribal councils may declare public health emergencies locally. Public health emergencies are illnesses or health conditions that pose a significant risk to communities that are either occurring or may imminently occur. As a recent example, COVID-19 was a public health emergency.

Similarly, the U.S. Surgeon General, who oversees the U.S. Public Health Service Commissioned Corps, may issue warnings or advisories about threats to public health. These statements are meant to raise awareness about a critical public health issue and offer recommendations for addressing it. For example, a [May 2023 advisory](https://openstax.org/r/hhsgov) (<https://openstax.org/r/hhsgov>) called attention to the mental harm that the near-universal use of social media may precipitate for youth in the United States (HHS, 2023b). Beyond government officials, professional associations may also identify and declare public health crises. For example, leading organizations such as the National Association of School Nurses, the American Heart Association, and the Association of Black Psychologists have declared racism a public health crisis (Kuehn, 2021; National Association of School Nurses, 2020; Vandiver, 2020).

New diseases, weather incidents, or concerning changes in data regarding a health condition may prompt officials at the federal level to explore a public health issue. Experts assess and evaluate the threat of the condition or incident to the public's health. To qualify as a public health emergency, the health threat must be imminent, significantly risk the public's health, and require a timely and comprehensive response. Declaring a public health emergency serves several purposes. First, the general public, health care workers, community partners, legislators, and others may become aware of important health issues. Additionally, public funding may be made available to support relief, recovery, and health improvement efforts related to the health problem. The HHS maintains a chronological [Declarations of a Public Health Emergency](https://openstax.org/r/asprhhsg) (<https://openstax.org/r/asprhhsg>) listing of public health emergencies nationally and for specific states/territories.

Public health emergencies, crises, or matters of interest evolve over time in response to disease spread, sociopolitical climates, the impact of conditions on the community, and other factors. A public/community health nursing student could likely list 10 public health topics that are currently a threat to societal health and require intervention. As an example, the Surgeon General recently issued a warning about the impact of social media on the mental health of adolescents (HHS, 2023b). The warning, in part, served as a call to action for clinicians, lawmakers, families, educators, and all citizens and recommended ways to address this health threat that targeted different groups, such as legislators, social media companies, adolescents and their families, and researchers, with a goal of developing ways to maximize social media's benefits and minimize its harms. For some adolescents, time on social media can facilitate connection, provide a creative outlet, and serve as a source of support. For others, social media can promote disordered eating, body dissatisfaction, low self-esteem, depression, and anxiety (HHS, 2023b).

Social media and youth mental health is only one current public health problem drawing the attention and efforts of legislators, public/community health nurses, and other colleagues. Public health problems span a spectrum of challenges, such as infectious disease outbreaks, natural disasters, and pathologic diagnoses among community members. Public health problems can exceed available resources, disrupt community stability, and bring harm or risk to community members. A strong public health system, with nurses leading change and advancing community health, plays a pivotal role in ameliorating public health problems through facilitating collaboration, sharing accurate information, appropriately allocating resources, and providing direct care and intervention.

HOW PUBLIC HEALTH WORKS—AND WHY IT SOMETIMES DOESN'T

[Access multimedia content](https://openstax.org/books/population-health/pages/2-2-historical-perspectives-on-publiccommunity-health) (<https://openstax.org/books/population-health/pages/2-2-historical-perspectives-on-publiccommunity-health>)

This *CBS Sunday Morning* news segment covers modern public health triumphs, problems, systems, and opportunities.

Watch the video, and then respond to the following questions.

1. The news clip features restaurant inspections and helmet use promotion as two public health interventions. What other public health interventions are happening in your area outside of hospitals and clinics?
2. Think of a public health policy. List at least one way that each of the organizations (federal agencies; state, tribal, local, and territorial health departments; government agencies; clinical care delivery systems; media; community-based organizations; private nonprofit associations; educational institutions; and private industry) displayed in the video are involved.

2.3 The Importance of Public/Community Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 2.3.1 Identify collaborative efforts across the U.S. public health system to improve the nation's health.
- 2.3.2 Explain the public health system's role in addressing population health needs.
- 2.3.3 Discuss public health funding and spending in the United States.

Public health operates as a large, interconnected network, at times referred to as the **public health system** (Figure 2.4). Several leading organizations collaborate with local public health departments to improve the nation's health. They include governmental organizations, nonprofits, colleges, universities, and community-based partners that share data, resources, expertise, and programs while working together to comprehensively improve health. Collaboration among public health agencies improves the efficiency and quality of public health via the synergy of resources and facilitates a holistic approach to improving health (Axelsson & Axelsson, 2006). Although some health organizations may differentiate their scope and practices to focus on specific health issues instead of public health broadly (Axelsson & Axelsson, 2006), the need for inter-organizational collaboration grows as health conditions and determinants become more complex. [Caring Across Practice Settings](#) explores public health governance and finance structures, agencies, and functions.

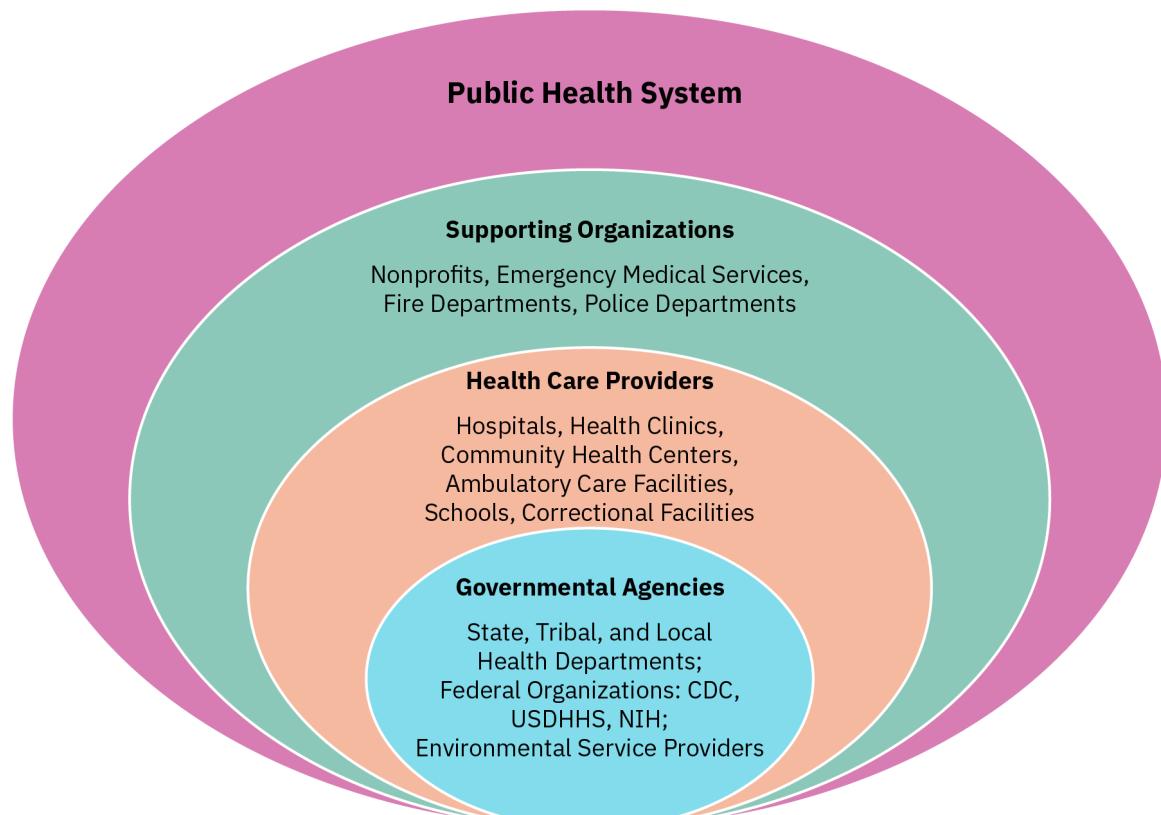

FIGURE 2.4 The U.S. public health system comprises many organizations at the national, state, and local levels. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Public/Community Health Funding

Robust public/community health programs are essential to the health of the community, a nation, and the global population. Public/community health programming can be expensive. Cumulatively, federal, state, and local governments are estimated to spend \$93 billion per year on public health (Alfonso et al., 2021). Although this sum may seem sufficient to fund quality public health programs, experts have noted that due to previous budget reductions, the United States is ill-equipped to adequately respond to the COVID-19 pandemic with this amount of funding (Alfonso et al., 2021), let alone other public health programs that address ongoing national health concerns.

Public/community health professionals must be paid. They need physical space, such as offices and clinics, to conduct their work, which may also require costly or vast quantities of supplies to positively impact the community's health. Money may be needed to create flyers or other advertisements to inform community members about new health initiatives. Despite these costs, public health programs can demonstrate a positive return on investment, meaning each dollar invested in the public health program returns money to the larger economy. See [What Is Population Health?](#) for more discussion of cost savings and earnings. However, public health funding has been decreasing since as early as the early 2000s despite its benefits to population and economic health. (Kuehn, 2011). For example, in 2020, just as COVID-19 was declared a public health emergency, the U.S. federal government proposed a 16 percent reduction of funding to the CDC and a 40 percent decrease in the amount of money provided to the World Health Organization as well as cuts to public health and well-being assistance programs (Devi, 2020). Some lawmakers lack personal exposure to the advantages of public health, and it may not be apparent to them that their constituents benefit from robust public health systems. Nurses play a pivotal role in advocating for public and community health program funding, possessing a unique vantage point to create programs and observe their positive effects on the health of communities and the general public.

Strengthening Health Through Collaboration

Some popular initiatives for public health collaboration include coordinating health care services, applying a population perspective to clinical practice, identifying and addressing community health problems, and strengthening health promotion and health protection (Shahzad et al., 2019). Some examples of collaboration include the following:

- [Centers for Disease Control and Prevention \(<https://openstax.org/r/cdcgova>\)](#): The CDC collaborates with federal, state, and local public health partners to promote health, reduce risk, and prevent disease. The CDC has developed initiatives and programs for many health conditions that local public health departments may access, adapt, and disseminate. The CDC also provides disease surveillance and mitigation guidance in times of large-scale outbreaks or if a notifiable infectious disease occurs. **Notifiable infectious diseases** require health care providers to report the disease to public health officials. Reporting is mandated by law at state and local levels, whereas reporting to the CDC is voluntary. The notifiable infectious diseases are selected for mandated reporting for reasons of contagiousness, severity, or frequency (CDC, 2022). The CDC collects data from all 50 states, New York City, the District of Columbia, Guam, the Marshall Islands, the Northern Mariana Islands, Puerto Rico, and the U.S. Virgin Islands (CDC, 2023b). Some examples of nationally notifiable or locally reportable infectious diseases are hepatitis A, chlamydia, anthrax, botulism, malaria, and rabies (CDC, 2023a). Client samples used to diagnose these reportable diseases must undergo further testing at a state laboratory or the CDC. In rural areas, transporting the samples in a timely manner for needed further testing can be difficult. Watch [this video \(<https://openstax.org/r/cdcgovnnd>\)](#) for an example of a CDC collaboration with courier services to support public health in Utah.
- [Healthy People 2030 \(<https://openstax.org/r/healthgovheal>\)](#): The Healthy People 2030 program is administered by the U.S. Department of Health and Human Services, Office of Disease Prevention and Health Promotion (ODPHP). The program has identified priority actions and tactics that the country must take to improve health outcomes for the public over the next decade. The program objectives span all body systems and many determinants, requiring collaboration from diverse groups and agencies. In fact, a major factor in the success of the Healthy People programs over time has been collaborative efforts to elevate and sustain public health (Hasbrouck, 2021). Visit [this blog \(<https://openstax.org/r/healthgovnews>\)](#) to learn about collaborations between the Iowa Department of Health and Human Services and the Healthy People Program to improve public health in the state.

- [National Association of County and City Health Officials \(https://openstax.org/r/nacchoo\)](https://openstax.org/r/nacchoo): This organization supports and represents local public health departments nationwide. Member departments can network and collaborate on specific initiatives or share successes and challenges faced when implementing programming. The organization also provides education, resources, and advocacy for policies and practices that promote public health and maximize support and uptake of local offerings. They have [over 50 formal partnerships \(https://openstax.org/r/wwwnaccho\)](https://openstax.org/r/wwwnaccho) with other organizations that advance health for specific populations.
- [National Institutes of Health \(https://openstax.org/r/wwwnihgo\)](https://openstax.org/r/wwwnihgo): The NIH conducts research and supports researchers studying public health issues and testing interventions to improve public health. The NIH collaborates with hospitals, clinicians, colleges and universities, and other research sites to address important public health issues, develop programs and interventions, and promote public health practices based on the latest evidence.

HEALTHY PEOPLE 2030

Reduce Cases of Pertussis Among Infants

Pertussis (also known as whooping cough) is a nationally notifiable disease. It is a contagious illness that can cause cough, fever, and other symptoms. For some people, the illness may be mild; however, infants are at an increased risk for hospitalization and death from this virus, especially because they are not able to become vaccinated until they are 2 months old. A goal of Healthy People 2030 is to [decrease the number of cases among infants \(https://openstax.org/r/healthgovhealthaaa\)](https://openstax.org/r/healthgovhealthaaa). Thus far, the goal has been met and exceeded. One reason for a decrease in pertussis among infants is encouraging vaccination among pregnant people in the third trimester and of close adult contacts of infants to prevent spreading the virus.

CASE REFLECTION

Collaborating to Support Client Health

Read the scenario, and then respond to the questions that follow.

You are learning more about the health and determinants that shape the health of the Lee family:

- The city where the Lee family lives has been experiencing a drinking water crisis for several years. Alexandra or Christopher must go to a city building once a week to obtain drinking water for the family. The family is also supposed to bathe in this water, but the city does not provide enough water for drinking, cooking, and bathing.
 - Alexandra, Sunshine, and Woody receive health plan coverage through a publicly funded state plan. As the plan only covers pregnant people and children, Christopher does not have health plan coverage. His hypertension is not being treated, and he has not seen a clinician in a few years.
1. What agencies might collaborate to address the drinking water crisis?
 2. Are there any organizations or resources for Christopher to obtain health care or health guidance? What is the role of public health in managing his hypertension and supporting adequate access to care?

Public Health as a Population Health Support

With a focus of improving health for the entire general public, the public health system plays a critical role in supporting population health. Remember, population health focuses on the health outcomes for groups of people with consideration for the environmental, economic, social, behavioral, and other factors that influence health. Public health focuses on population monitoring and policy and program development that are carried out to achieve positive population health outcomes.

Illness surveillance and monitoring are one way public health supports population health. Public health departments and organizations collect and analyze data on the population's health to build a complete picture of rates of disease, injury, contamination, contagiousness, health impact, and other variables or indicators. They collect data through various channels, including targeted surveys and formal surveillance systems, such as hospital or county reports. All of this is done to predict emerging health threats and determine which health conditions

require intervention via resource allocation, programming, or policy implementation. Data can also be used to identify disparities, address social determinants of health, and support equitable access to health services or a healthy life. See [Pandemics and Infectious Disease Outbreaks](#) for more information on surveillance and detection.

Another example of public health facilitating population health is in emergency preparedness and response. Public health emergencies might include disease outbreaks, pandemics, natural disasters, or terrorism. Public health organizations plan for emergencies and develop response plans that guide the actions of individual people, families, schools, and other community organizations. Public health organizations may also ensure that people can practice evacuation and survival tactics before an emergency occurs. See [Principles of Disaster Management](#) for more information on the nurse's role in emergency preparedness and response.

Public health efforts prevent disease, promote health, and reduce risk. The strategies and policies that public health systems develop, promote, or enforce, such as vaccine requirements, nutrition counseling, access to outdoor exercise, indoor smoking bans, and alcohol consumption guidelines, reduce the burden of disease and risk to individuals and the community to improve the health of the general population ([Figure 2.5](#)).

FIGURE 2.5 Public health policy efforts supporting population health led to smoking bans in public places. Before the mid-1990s, smoking was legal in schools, restaurants, airplanes, and hospitals. When indoor smoking bans took effect varied by state, but the health consequences for smokers and nonsmokers alike have improved. Check out [this website](https://openstax.org/r/wwwcdcgovto) (<https://openstax.org/r/wwwcdcgovto>) to read about the impact of indoor smoking bans on workers across industries. (credit: "GRCC Smoking Ban" by Becky Spaulding/Flickr, CC BY 2.0)

2.4 The Core Functions and Essential Services of Public Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 2.4.1 Identify the 10 Essential Public Health Services.
- 2.4.2 Explain how the 10 Essential Public Health Services serve as a framework for addressing systemic and structural barriers contributing to health inequities.
- 2.4.3 Identify the three core functions of public health.
- 2.4.4 Describe how the 10 Essential Public Health Services align with the three core public health functions.

The CDC has identified [10 Essential Public Health Services](https://openstax.org/r/wwwcdcgov) (<https://openstax.org/r/wwwcdcgov>) that all communities should use to protect and promote health. They include (CDC, 2023d):

1. Assess and monitor population health status, factors that influence health, and community needs and assets
2. Investigate, diagnose, and address health problems and hazards affecting the population

3. Communicate effectively to inform and educate people about health, factors that influence it, and how to improve it
4. Strengthen, support, and mobilize communities and partnerships to improve health
5. Create, champion, and implement policies, plans, and laws that impact health
6. Utilize legal and regulatory actions designed to improve and protect the public's health
7. Ensure an effective system that enables equitable access to the individual services and care needed to be healthy
8. Build and support a diverse and skilled public health workforce
9. Improve and innovate public health functions through ongoing evaluation, research, and continuous quality improvement
10. Build and maintain a strong organizational infrastructure for public health

Public health professionals use these essential services to address health issues across the United States and ultimately improve population health outcomes. The 10 Essential Public Health Services do not expressly focus on health inequities and disparities; however, applying these principles to public health activities can help facilitate health justice across the population.

The essential services align with the [three core functions of public health \(<https://openstax.org/r/malphorgs>\)](https://openstax.org/r/malphorgs). The three core functions of public health include assessment, policy development, and assurance (CDC, 2023d).

- Assessment involves collecting and evaluating data to identify the health needs of populations. Public health professionals monitor health trends, identify health disparities and injustices, and identify health problems requiring intervention and resource support. Public health nurses may conduct health surveys, collate epidemiological data, determine existing health infrastructure in a community, and identify health needs.
- Public health professionals also develop policies or work with lawmakers to ensure policies support public health. Nurses in public health may evaluate evidence and engage affected community members to develop policies considering local social, economic, political, and other contextual factors.
- Assurance is a core function that facilitates justice. When the full depth and breadth of public health services, encompassing everything from ensuring clean air to providing vaccines and empowering clients to participate in the policy process, is available to all clients, the public health system is actively working to ensure health is attainable for all.

The core functions of public health are carried out via activities specified in the 10 Essential Public Health Services. Please see [Table 2.1](#), which displays connections between the 10 Essential Public Health Services and the core functions of public health as well as examples of activities public health professionals may employ to address systemic and structural barriers that contribute to inequities in health and care.

Essential Public Health Service	Core Function	Activity to Address Health Inequities
1. Assess and monitor population health status, factors that influence health, and community needs and assets	Assessment: Public health agencies and professionals collect, analyze, and evaluate data to understand the barriers, opportunities, and status of health in a population. Data are also used to identify health disparities and determine the need for resources to facilitate health and ameliorate injustices.	Identify inequities and monitor progress in ameliorating them
2. Investigate, diagnose, and address health problems and hazards affecting the population	Assessment, assurance: Public health agencies and professionals study data to understand health problems and health risks, identify causes, and determine the best interventions to address health issues.	Examine and describe the causes of health inequities, including social determinants, exclusive policies, or inequitable access to health services and programming
3. Communicate effectively to inform and educate people about health, factors that influence it, and how it can be improved	Assessment, policy development, assurance: Effective communication raises awareness and secures support for public health issues. Through effective communication, public health information is shared with community members and affected groups. Healthy behaviors and engagement in current public health services can be promoted. Effective communication supports involvement of community members as they can access accurate and timely health information and services.	Provide accessible and evidence-based health information to all people to empower clients, families, and communities in their own health processes
4. Strengthen, support, and mobilize communities and partnerships to improve health	Policy development, assurance: Public health agencies and professionals collaborate with communities, organizations, affected groups, and other key parties to build partnerships and develop resources that address health needs and improve health outcomes.	Meaningfully involve community organizations, local leaders, or affected groups to identify barriers to health equity and develop strategies to address them that the community finds realistic, useful, and acceptable
5. Create, champion, and implement policies, plans, and laws that impact health	Policy development: Policies are developed with support from and in response to the public health data collected and to prevent disease, avoid harm, and reduce risk in the community.	Ensure policies, plans, and laws facilitate equitable distribution of health resources and promote health equity across communities

TABLE 2.1 Essential Public Health Services, Core Functions, and Activities to Address Health Inequities

Essential Public Health Service	Core Function	Activity to Address Health Inequities
6. Utilize legal and regulatory actions designed to improve and protect the public's health	Policy development, assurance: Public health departments and other agencies may implement and enforce regulations that protect the health of the public.	Ensure compliance with policies and programs developed to improve health equity, from nondiscriminatory practices to those that support healthy environments for all communities
7. Ensure an effective system that enables equitable access to the individual services and care needed to be healthy	Assurance: Public health professionals work to ensure that all population members can access health services regardless of their current health, employment, education level, or other determinants. Public health agencies reduce barriers to care to facilitate equity in access and opportunity.	Remove barriers to accessing care through promoting the availability and access of health services, clinics, mental health services, social programs, and other resources
8. Build and support a diverse and skilled public health workforce	Assurance: The public health workforce must have strength in numbers to adequately address health needs and strength in diversity and inclusion so that the workforce approximates the characteristics of the community served.	Promote inclusion and belonging in the public health workforce to support a more comprehensive understanding and community-relevant response to problems from public health agencies
9. Improve and innovate public health functions through ongoing evaluation, research, and continuous quality improvement	Assessment, assurance: Public health agencies evaluate programs and policies continuously to determine effectiveness, identify areas for opportunity, and ensure that resources are properly allocated to support health.	Include measures of equity and access in ongoing evaluation to inform quality improvement initiatives that lead to better population health outcomes related to reducing health disparities
10. Build and maintain a strong organizational infrastructure for public health	Assurance: Public health organizations, agencies, or departments carry out many functions essential to the well-being of the population. Administrative systems; information technology; and professionals to assess, plan, deliver, and evaluate services are just a few essential departments and duties of a public health organization that require adequate funding, equipment, technology, space, and personnel.	Guide organizational planning with principles of justice, belonging, equity, and inclusion to ensure eliminating disparities and inequities is a priority in public health

TABLE 2.1 Essential Public Health Services, Core Functions, and Activities to Address Health Inequities

[Public/Community Health in Practice](#) will discuss how nurses in public/community health carry out the 10 Essential Public Health Services and three core functions of public health.

2.5 Levels of Prevention

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 2.5.1 Identify and differentiate between the five levels of prevention in public health.
- 2.5.2 Differentiate public health efforts according to one of the three levels of prevention.

Much of public health focuses on prevention—preventing injuries, preventing acute illnesses, preventing chronic conditions, even preventing unexpected death. The five levels of prevention in public health are primordial, primary, secondary, tertiary, and quaternary (Figure 2.6). Not all public health professionals or nurses may consider primordial and quaternary prevention in their work; the concepts of primordial and quaternary prevention entered the health care lexicon in 1978 and 1986, respectively, while the other three levels of prevention are familiar to generations of clinicians (Kisling & Das, 2023; Martins et al., 2018).

Levels of Prevention in Public Health

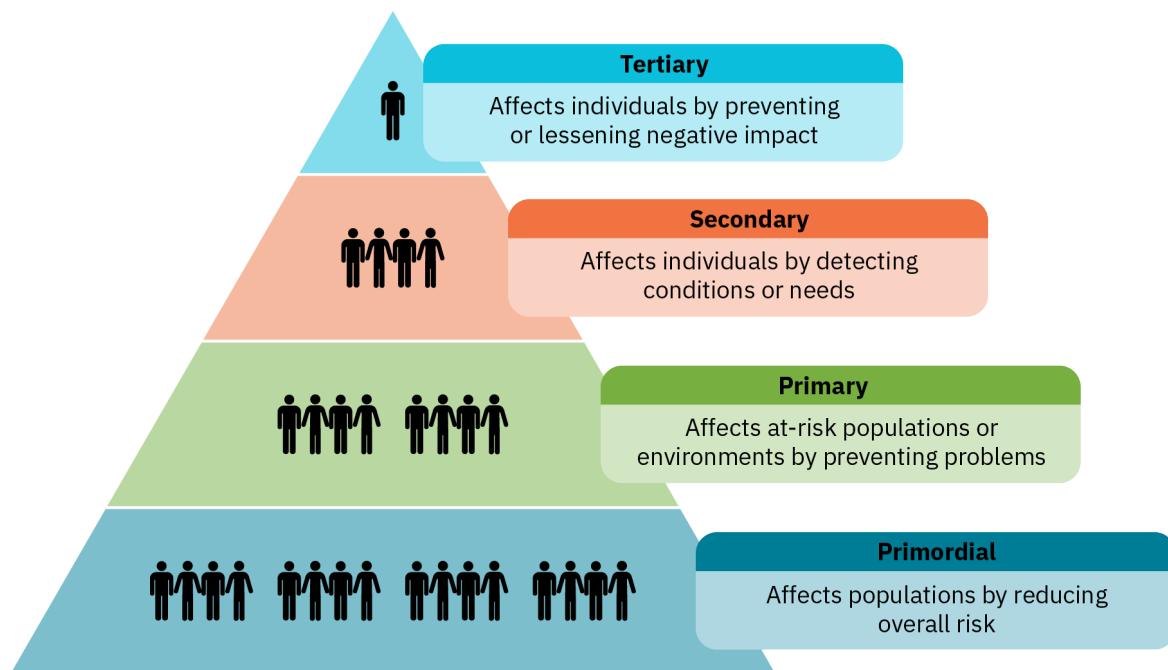

FIGURE 2.6 Levels of prevention in public health focus on different strategies to improve population health outcomes. (See U.S. Department of Health and Human Services, 2023a; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

- **Primordial prevention** focuses on risk factor reduction for an entire population and is usually carried out through large social changes and national policy (Falkner & Lurbe, 2020).
 - The American Heart Association has emphasized following the DASH diet (dietary approaches to stop hypertension), participating in physical activity, keeping a healthy body mass index, avoiding smoking, and consuming low or no alcohol as primordial prevention strategies to avoid risk factors for poor cardiac health (Lloyd-Jones et al., 2021).
- **Primary prevention** involves interventions to prevent an adverse health outcome from occurring. Primary prevention interventions may target the population, groups, and communities at high risk of a particular condition. Immunizations and education on healthy lifestyle factors are two examples of primary prevention strategies.
 - Medication overuse headache occurs when those who experience headaches take medications to address their pain but then have rebound headaches from using medications too often. A group of researchers designed and implemented an education campaign and guidance for primary care providers and clients on stopping overused medications to prevent this type of headache (Diener et al., 2019).
- **Secondary prevention** focuses on early disease detection to diagnose conditions early and promptly treat them to stop or slow progression and minimize impact. Screening is the primary activity in secondary

prevention, but other activities may be conducted.

- During an ischemic stroke, blood flow to part of the client’s brain is blocked. Following identification of an ischemic stroke, a secondary prevention strategy includes surgical placement of a stent to help restore blood flow (Diener & Hankey, 2020).
- **Tertiary prevention** strategies aim to lessen the negative impact of a health condition and prevent complications. Treatment through medications, surgical procedures, complementary modalities, therapies, and rehabilitation approaches are tertiary prevention activities.
 - Researchers studied an intervention to help individuals who are unhoused during the transition to becoming housed. Over six months, youth who were unhoused received outreach-based case-management services, individual and group mental health support, and peer support. Following program participation, the youth displayed gains in employment, education, and connection to mental health services (Kidd et al., 2019).
- **Quaternary prevention** aims to protect clients from health interventions that might cause more harm than good (Martins et al., 2018). To carry out quaternary prevention, clinicians attempt to avoid conducting tests and exams that are not essential to the client’s plan of care or well-being. For social problems, public health professionals address the risks and harm associated with excessive intervention.
 - For example, if a client presented to the urgent care clinic with a runny nose, cough, and no fever for three days with clear lung sounds, the clinician may reason that the client has a viral upper respiratory infection instead of a bacterial upper respiratory infection. Antibiotics would not be needed given the likely viral cause. Additionally, a viral panel to determine the causative agent would yield interesting results but would not change the client’s plan of care. Regardless of the virus, the client would be asked to avoid other people and public spaces, possibly wear a surgical mask when around others, hydrate, get rest, and use over-the-counter medications as needed.

[Table 2.2](#) provides some examples of the levels of prevention applied to different health conditions. Of note, quaternary prevention is not included in the table, as the quaternary activities are generally focused on what clinicians should *not do*.

Condition	Primordial	Primary	Secondary	Tertiary
Cervical cancer	Mandating health plan coverage of cervical cancer screening tests	HPV vaccine administration	Cervical cancer screening tests	Electrosurgical excision to remove diseased tissue from the cervix
Preeclampsia	Mandating health plan coverage of prenatal visits	Blood pressure monitoring and urine testing during pregnancy	Medications to control blood pressure	Immediate delivery of the baby on conversion to eclampsia
Migraine	Promoting migraine-friendly schools and offices	Educating individuals about migraine triggers	Medications for symptom relief and prevention	Specialized infusions for chronic pain management
Influenza	Use of masks, handwashing, and cough courtesy	Annual vaccine administration	Rapid influenza testing	Antiviral treatments
Food insecurity	Funding of social safety nets to reduce poverty and food inaccessibility	Food assistance programs and community gardens	Referrals to food banks and government assistance programs	Employment assistance, financial literacy, and budget training

TABLE 2.2 Levels of Prevention Examples

Condition	Primordial	Primary	Secondary	Tertiary
Gun violence	Comprehensive gun control policies	Safe firearm storage education	Early identification of perpetrators and deployment of crisis response	Emergency care and support for victims
Youth social media and mental health	Positive digital citizenship and online behavior guidelines for students	Cyberbullying, privacy, safety, and screen time education	Twice-yearly mental health screenings in schools	Therapy programs to address mental health and promote coping strategies

TABLE 2.2 Levels of Prevention Examples

CASE REFLECTION

Levels of Prevention

Read the scenario, and then respond to the questions that follow.

You are working with the Lee family and focusing on the health of the children, Sunshine and Woody.

- Sunshine, life-threatening allergy: Sunshine just started kindergarten and has an epi-pen for a life-threatening nut allergy. She attended an after-school arts and crafts program twice a week but stopped going when Christopher lost his job. Her parents are considering home-schooling due to the increased incidence of school-based gun violence in America.
 - Woody, toddler who is generally healthy and attends the daycare where Alexandra works.
 - Sunshine and Woody love going to the park near their home with their parents. Both are excited to see their paternal grandparents, who will soon visit from South Korea.
1. What adverse health outcomes may occur but have not yet affected Sunshine and Woody? What are some related primary prevention interventions?
 2. Based on their ages, what secondary prevention activities should be completed?
 3. How may tertiary prevention activities be implemented for Sunshine's life-threatening allergy?
 4. What primordial prevention efforts in the Lee family's city, state, or nation could positively impact their health?
-

Chapter Summary

2.1 Defining Public Health

Health should be attainable for all people. Public health facilitates health for all through organized efforts to prevent disease, reduce risk and disparities, and promote health. Educational programs, policies, health services, research, and direct care are all part of public health. While public health addresses the upstream and downstream factors of health conditions, its focus is upstream factors. Public health differs from population health in the focus and scope of work. Population health focuses on actions and initiatives of the health system to improve health outcomes. Public health involves collective action, public policy, governance, and health services to promote and protect the health of the population. Both specialty arms aim to achieve favorable health conditions for all.

2.2 Historical Perspectives on Public/Community Health

Historical events have shaped public health as a field and group of services. For example, the Industrial Revolution inspired changes to public health policies surrounding sanitation, workplace safety, and the existence of public health departments. Changes such as reforms in worker safety, sanitation, and establishing public health departments were driven by collective action and societal pressure. Concerns regarding environmental health threats and worker health remain, highlighting the need for ongoing public health efforts and a strong public health workforce. The work of public health in supporting health for all continues today. Public health activities, guidelines, policies, and regulations are essential in promoting health, reducing risk, preventing disease, and advocating for the health of all.

2.3 The Importance of Public/Community Health

Collaboration is needed to improve the nation's health. Different entities share data, resources, expertise, and programming to comprehensively improve public health. Collaborations may involve coordinating care services, applying the population perspective to clinical practice, identifying and addressing public health problems, and strengthening health promotion and risk

reduction to provide a holistic approach to addressing complex health issues. Healthy People 2030 identifies priority actions and tactics for improving public health that are reviewed and used to shape local policies and programming. Public health plays a critical role in supporting population health. The strategies and policies that public health systems develop, promote, or enforce all reduce the burden of disease and risk to improve the general population's health.

2.4 The Core Functions and Essential Services of Public Health

The CDC identified 10 Essential Public Health Services that can be used to guide health promotion and protection activities. Essential services include assessing population health, investigating and addressing health problems, effective communication, community mobilization, policy development, legal actions, equitable access to care, building a skilled workforce, evaluation and research, and supporting organization infrastructure. The essential services align, and work in concert, with the three core functions of public health: assessment, policy development, and assurance. Assessment involves collecting and evaluating health data, policy development involves creating regulations supportive of health, and assurance supports access to services for everyone.

2.5 Levels of Prevention

The five levels of prevention in public health are primordial, primary, secondary, tertiary, and quaternary. Primordial prevention focuses on reducing risk factors for the public through social change and large-scale policy. Primary prevention aims to prevent adverse health outcomes, especially in high-risk populations or individuals. Tertiary prevention involves treatment to minimize the negative impact of a health condition and prevent complications. When professionals work to protect individuals from unnecessary interventions, they are engaging in quaternary prevention. Initiatives at each level contribute to promoting health and reducing the burden of disease.

Key Terms

colonialism the practice of powerful nations asserting control and exploiting other nations for political or economic purposes
community health a specialty area of nursing and

health practice focused on the health and risks of a specific locality or community of people
notifiable infectious diseases diseases that, when identified, require health care providers to report

<p>the occurrence to public health officials</p> <p>paternalism authority figures making decisions for others in a manner that suppresses their identity and autonomy</p> <p>primary prevention initiatives that aim to prevent an adverse health event from occurring, such as immunizations and health promotion education</p> <p>primordial prevention initiatives that aim to reduce risk for a disease or condition across an entire population, such as social change and national policy</p> <p>public health a specialty area of nursing and health practice focused on supporting the well-being of society through organized efforts to ensure health is attainable for all</p> <p>public health emergencies illnesses or health conditions that pose a significant risk to communities that are either occurring or may imminently occur; the risk may be a substantial</p>	<p>number of fatalities or disability</p> <p>public health system a network of institutions, agencies, organizations, and resources that collaborate to promote, protect, and improve the health of populations and communities</p> <p>quaternary prevention actions and decisions that protect overmedicalization of clients; protecting clients from interventions that might cause more harm than good</p> <p>secondary prevention initiatives implemented to detect diseases or health conditions early on in their course so they can be diagnosed early and promptly treated to stop or slow progression and minimize impact; screening is the primary activity in secondary prevention</p> <p>tertiary prevention initiatives that aim to lessen the negative impact of a health condition and prevent complications</p>
---	---

Review Questions

1. Which action must the nurse take after a patient has been diagnosed with hepatitis A?
 - a. Notify the Centers for Disease Control and Prevention
 - b. Report the case to the local public health department
 - c. Inform the National Institutes of Health
 - d. Report the case to the primary care provider

2. Which of the following is an upstream intervention that a nurse may employ to address the high rate of sedentary lifestyles in a community?
 - a. Counseling community members on the negative health effects of being sedentary
 - b. Conducting body mass index screenings during a community health fair
 - c. Obtaining funding for community walking trails
 - d. Sending mailings with exercise tips to community residents

3. Which action describes a role of the nurse in public health?
 - a. Improving individual outcomes
 - b. Addressing racism in a community
 - c. Performing a family assessment
 - d. Recommending policies to prevent health problems

4. A community health nurse is teaching nursing students about the development of the modern public health system. Which reform movement will the nurse note as foundational to the modern public health system?
 - a. Smoking tobacco indoors
 - b. Child labor and working conditions
 - c. Drinking water cleanliness
 - d. Opioid prescribing

5. Which example demonstrates a nurse using public health data collection in support of population health?
 - a. Surveying middle school children to identify which fruits and vegetables to include in school lunches
 - b. Tracking attendance at a weekly blood pressure clinic at the local senior center to measure utilization
 - c. Analyzing data from hospitals to identify the most common illnesses requiring emergency visits
 - d. Interviewing a family living in an urban area to describe the emotional impact of gun violence

6. Which data would the nurse monitor when engaged in the public health core function of assessment?
 - a. Blood pressure readings in an individual
 - b. Health trends of a community
 - c. Social supports of a family
 - d. Immunization records of elementary school children
7. Which activity by the nurse supports the core function of assurance in public health?
 - a. Surveying a population to determine health knowledge deficits
 - b. Developing policies in collaboration with an interprofessional team
 - c. Monitoring health data trends
 - d. Ensuring access to health services for all
8. Which goal by a public health nurse is an example of quaternary prevention?
 - a. Reducing the negative impact of a health condition and preventing complications
 - b. Focusing on the early detection and treatment of disease to minimize impact
 - c. Implementing policies to address the root cause of health issues and reduce disparities
 - d. Protecting individuals from unnecessary interventions that may cause more harm than good
9. Which action by the community health nurse best describes tertiary prevention?
 - a. Avoiding the overmedicalization of clients
 - b. Reducing risk factors across a population
 - c. Lessening the negative impact of health conditions
 - d. Preventing an adverse health outcome from occurring
10. Which action by the nurse is a primary prevention strategy?
 - a. Implementing a comprehensive education program for individuals with heart disease
 - b. Designing a program to support the transition of young families to parenthood
 - c. Recommending exercise programs to clients with degenerative joint disease
 - d. Educating adolescents about reducing the risk of sexually transmitted infections

CHAPTER 3

Public/Community Health in Practice

FIGURE 3.1 A school nurse in a rural setting examines a client in collaboration with a nurse practitioner via telehealth. Community health nurses serve many roles and can bridge the gap between distant specialists and clinicians by providing essential care directly to people in their homes and communities. (credit: modification of work by Preston Keres/USDA/Flickr, Public Domain)

CHAPTER OUTLINE

- 3.1 Defining Public/Community Health Nursing
- 3.2 Public/Community Health Nursing Scope of Practice, Core Competencies, and Function
- 3.3 Public/Community Health Nursing Practice

INTRODUCTION Public/community health nurses act as change agents in their communities, working to support health outcomes for clients and the broader population. They play a pivotal role in advancing the health of clients, communities, and families and in achieving population health objectives. The actions of public/community health nurses align with the principles and functions of public health: assessment, assurance, and policy development. This chapter will explore historical perspectives on public/community health nursing, the foundation and functions of professional practice, and how public/community health nurses lead and deliver care across levels of prevention to show how the connection between nursing practice and public health supports population health.

As [Foundations of Public/Community Health](#) notes, the term “public/community health” is fairly common as the goals and functions of these closely related disciplines are interconnected. In nursing, community health has long been viewed as indistinguishable from public health (American Nurses Association [ANA], 2022, p.3.)

This chapter will continue to refer to Alexandra Lee and her family, whom the text has been following since [What Is Population Health?](#) to explore how population, public, and community health impact their well-being. Remember that the Lee family members include parents Alexandra, a daycare teacher who is pregnant, and Christopher, who has hypertension and is currently without a job or health plan coverage, and their children Sunshine, a full-time school student with a life-threatening allergy, and Woody, a generally healthy toddler.

3.1 Defining Public/Community Health Nursing

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 3.1.1 Define community health nursing practice.
- 3.1.2 Describe major historical events and factors that have shaped public health nursing practice.
- 3.1.3 Identify nurse leaders who have influenced public health practice.

Community health refers to a community's physical, mental, and social well-being and involves health promotion, risk reduction, and disease prevention efforts to support health. Nurses in community health care for an entire community. They identify, assess, and respond to the health needs of populations (Kulig, 2000). A **community** is a group of people with at least one characteristic in common. The characteristic may be a place, a personal attribute, or a common goal. Every community has individuals with health problems and health risks. For example, members of communities that lack access to clean drinking water share health risks related to the harmful chemicals in their water, dehydration, and concern about a water crisis. A community situated near a busy highway may notice increased rates of hearing loss. Yet another community may see high rates of gun violence, leading to fewer children engaging in outdoor play. All communities, regardless of location or their members' personal characteristics, have health risks and health needs and can benefit from the involvement of nurses with expertise in providing population health care. Remember, population health is an approach to supporting the health of people through research, data analysis, and health programming that considers the impact of public policy, environmental, social, behavioral, and other factors that might facilitate or hinder health for all.

CASE REFLECTION

Addressing a Water Crisis

Read the scenario, and then respond to the questions that follow.

The Lee family lives in a two-bedroom apartment in a quiet residential neighborhood. They can walk to a playground and walk or take public transit to other community spaces, but their city has a major problem. For years, the city has lacked adequate safe drinking water. Alexandra or Christopher must go to a city building once per week to obtain drinking water for the family. The family is supposed to bathe in this water, but the city does not provide enough water to satisfy drinking, cooking, and bathing needs.

1. What are the consequences of not receiving enough water to support drinking, cooking, and bathing?
2. Given the health status of Alexandra, Christopher, Sunshine, and Woody described in [What Is Population Health?](#) and [Foundations of Public/Community Health](#), what risks do they face living in a city with a water crisis?
3. How can nurses contribute to addressing water crises?

Public/Community Health Nursing Historical Perspectives

In 1949, the National Organization of Public Health Nurses (the leading organization at the time) distinguished community health nursing from public health nursing (Kub et al., 2015). In a position statement, the organization stated that community health nursing involved caring for individuals and families with the latest available interventions of the post–World War II era, whereas public health nursing was primarily concerned with population-based strategies (Abrams, 2004). Some nursing experts consider that community health nursing fully emerged as a distinct specialty in the 1960s, describing the work of nurses who provided care not offered through government organizations (University of Maryland School of Nursing, 2023). Two decades later, the American Nurses Association (1980) convened an expert panel to develop a conceptual model of community health nursing. The panel defined community health nursing as a synthesis of general nursing practice and public health with a purpose of promoting and preserving the health of the population. Today, nurses who provide myriad services to communities across settings are recognized as community health nurses. Still, discourse continues within the nursing discipline regarding how public and community health nursing can be fully defined and distinguished as separate fields (Goodman et al., 2014; Kub et al., 2015; Schofield et al., 2011). As noted, the ANA (2022) views community and public health nursing as indistinguishable.

Many historical events have shaped public/community health nursing practice. Public/community health nurses have a role in responding to events that impact the population's health, whether the events center around war, struggle, progress, infectious diseases, or evolving social, cultural, and political influences. World War II, the emergence of HIV and AIDS, and the COVID-19 pandemic are three examples of events that presented opportunities for public/community health to change lives and for public/community health nurses to demonstrate their value.

World War II

In 1946, U.S. President Harry Truman described public/community health nurses as "one of the most important groups of health workers" following their contributions during the second World War (Associated Press, 1946). During that war nurses delivered care to the military and their families, the general public, and refugees. The independent nature and opportunities for leadership during combat care provision prompted many nurses to seek new professional roles with greater autonomy upon their return to the United States, and many found that public/community health nursing met this need (Barnum, 2011). Beyond the care nurses provided to manage acute and chronic health conditions, they educated the public to raise awareness of health and health issues, prevent the spread of diseases, and promote **vaccine uptake** (the proportion of the population receiving a vaccination).

The war era ushered in a baby boom, with 76 million births in the United States between 1946 and 1964 (Population Reference Bureau, 2023). This led to overcrowded labor and delivery units, and quick hospital discharges for birthing parents necessitated postpartum care as a part of public health. Public/community health nurses conducted home visits to provide postpartum care and led prenatal classes to support maternal/child health. Lawmakers and the public supported such nurse-led services due to a wartime rhetoric of maternal-child health as critical to military morale (Temkin, 1999).

Public/community health nurses were also critical in supporting veteran care and rehabilitation efforts following the war. As part of the national economic reconstruction, public/community health nurses became instrumental in addressing veterans' physical and emotional health needs (Buffum & Wolfe, 1995). As the oldest World War II veterans still need care, public/community health nurses continue to be involved in supporting community access, inclusion, and health for this population. From delivering care to promoting health through education and bringing care out of the hospital and to the public, public/community health nursing during this era highlighted the significant contributions of nurses in supporting a healthy population.

Legionnaires' Disease

Americans across the United States celebrated the nation's 200th birthday throughout 1976. The American Legion, a national nonprofit group supporting military veterans, held a convention of over 2,000 members in Philadelphia, Pennsylvania (Markel, 2018). Following the convention, several attendees sought care at the local Veteran's Administration hospital for a type of pneumonia that was unfamiliar to clinicians, was not diagnosed with typical testing, and failed to respond to antibiotics. Following four client deaths from this puzzling condition only 10 days after the convention ended, the hospital consulted the Centers for Disease Control and Prevention (CDC) for help in determining what was affecting the clients and why. In another two weeks, a total of 182 convention attendees (called *Legionnaires*) were ill, and 29 had died. In addition to the *Legionnaires*, a city bus driver, pedestrians who had been close to the convention hotel, and the hotel air-conditioning technician were ill. Ultimately, 182 people were infected and 29 died (Fraser et al., 1977). Investigations eventually identified a new deadly bacteria named *Legionella pneumophila* (McDade et al., 1977). The bacteria were able to cause a particularly concerning level of harm because they could be aerosolized and spread via the air-conditioning system. Today, the CDC continues to monitor rates of *Legionnaires'* disease in the United States, which have been on the rise since 2000 (CDC, 2021).

HIV and AIDS

In the 1980s, the first recognized cases of human immunodeficiency virus (HIV) emerged in the United States (Dorwick et al., 2023). This new disease, about which little was then known, significantly impacted public/community health nursing, as the speed and reach of infections reached pandemic levels. Similar to *Legionnaires'* disease, clients initially presented with an atypical pneumonia that puzzled clinicians. The lack of knowledge about the disease and how it spread contributed to a great deal of fear, stigma, and homophobia among members of the public and the health care community. Public/community health nurses needed to learn as much as possible about the virus quickly to help prevent its spread and manage the condition. They also needed to combat the fear and misconceptions that led to social isolation, medical neglect, or worse for people with HIV or autoimmune deficiency

syndrome (AIDS) or those thought to be at risk for having or spreading HIV. Some clinicians and members of the public even refused to shake hands with a person who they thought might have contracted HIV or might have developed AIDS for fear of contracting it. Compassion and setting an example were key aspects of the work of public/community health nursing in response to the HIV epidemic. Public/community health nurses provided direct care to individuals who were living with HIV or had developed AIDS. They were also involved in developing centers and units dedicated to providing care for those with HIV or AIDS in a safe, supportive, and comprehensive manner.

Cliff Morrison, a nurse who was instrumental in collaborating with the public health department and developing the first unit for people with HIV or AIDS in San Francisco, has said, "This is a disease that is more geared toward nursing than anything else that we've ever seen because there isn't that much that medical science can do, but there's a lot that nurses can do . . . the most important thing we can do is to touch our patients" (Vieites, 2020, para 9). Cliff and his nurse colleagues were subjects of the documentary *5B* about this first HIV and AIDS unit. Today, treatments for both HIV and AIDS have improved, and the stigma associated with the disease in the United States has abated, but there is still progress to be made. Modern nurses have been called the "backbone" of the successful delivery of services to people living with both HIV and AIDS, especially in the most affected areas of the globe (Guilamo-Ramos et al., 2021). Public/community health nurses provide education to prevent HIV transmission and to promote testing, treatment monitoring, and counseling as part of the ongoing efforts to combat HIV and AIDS globally. [Pandemics and Infectious Disease Outbreaks](#) covers the HIV and AIDS pandemic in more detail.

COVID-19 Pandemic and Beyond

Public/community health nurses were pivotal in the U.S. response, adaptation, and continued flexibility to the COVID-19 pandemic. Public/community health nurses have provided care and guidance to affected clients and families, shared information about evolving knowledge and best practices for disease mitigation and management, and worked exceptionally hard to prevent the spread and impact of the virus (Edmonds et al., 2020). One key role of public/community health nurses during the first 18 months of the pandemic was **contact tracing** and **disease surveillance**. Disease surveillance may consist of many data collection activities that aim to inform a disease response plan. Contact tracing involves identifying the people who may have been around a client with a particular disease and are therefore at risk of acquiring or spreading it. As part of their role in [contact tracing](#) (<https://openstax.org/r/whointnews>), nurses identified community contacts of clients with COVID-19. Once they had identified the close contacts, nurses would inform them of their exposure to a person with COVID-19, review their risk of infection, and share information on the importance of testing and isolating.

Public/community health nurses were also instrumental in ensuring that as many Americans as possible could be protected, and protect others, from infection through COVID-19 vaccination. These nurses were at the forefront of disseminating information to the public about the importance and availability of vaccinations, managing pop-up vaccine clinics, and administering vaccines to millions. Public/community health nurses also addressed vaccine hesitancy and misinformation through public presentations and via social media to ensure clients were accurately informed and ready to become vaccinated (Jones & James, 2021). Throughout the COVID-19 pandemic, public/community health nurses advocated for policies supportive of health for community members and fellow clinicians. Many nurses used their collective voices to lobby policymakers and collaborate with elected officials to ensure organizations had proper guidelines to support disease mitigation, sufficient personal protective equipment, and exclusion and return policies in line with rapidly evolving evidence.

Today, public/community health nursing practice must remain flexible in the face of the changes that major events may bring about. The passage of the Affordable Care Act (ACA) in March 2013 marked a pivotal moment in American history and health care, aiming to increase care accessibility for all. Now, over a decade later, a record number of Americans subscribe to health plans available per the ACA (Luhby, 2023). Efforts to address health disparities and promote health equity have been central to the practice of progressive leaders and health care clinicians alike. However, these objectives gained a renewed sense of urgency in the public and professional eye following a national reckoning with racism and equity in the wake of the murder of George Floyd (Ayanian & Buntin, 2020). Amid these major events, the concerning crisis in mental health care has persisted. An ongoing national epidemic of substance use disorders (National Institute of Mental Health, 2023), a shortage of mental health care clinicians (Counts, 2023), stigma about mental health (American Psychiatric Association, 2020), and the evolving influence of social media on well-being have exacerbated this crisis (Mass General Brigham McLean, 2023). Through public health events like the HIV and AIDS epidemic and the COVID-19 pandemic, history offers nurses valuable lessons to apply

to contemporary health problems. Despite progress in many areas of public/community health, research, innovation, expanded access to care, and a national commitment to health promotion and disease prevention are essential to meeting population health goals. [Leading the Way to Improving Population Health](#) provides more information on these and other contemporary health challenges.

PUBLIC HEALTH NURSES: THE FIRST LINE OF PREVENTION

[Access multimedia content \(<https://openstax.org/books/population-health/pages/3-1-defining-publiccommunity-health-nursing>\)](https://openstax.org/books/population-health/pages/3-1-defining-publiccommunity-health-nursing)

This video profiles public health nurses who discuss some of the challenges present before COVID-19 and some that were precipitated by the pandemic.

Watch the video, and then respond to the following questions.

1. Which activities discussed in the video were most easily adapted to remote implementation? Which activities were likely challenging to implement in a remote setting?
2. How did you interact with public/community health nurses during the pandemic?
3. How should public/community health nurses, other health care providers, and the public leverage the increased visibility of public/community health nursing in the wake of the pandemic to secure support for this specialty?

Public Health Nurse Leaders

From advocating for policy reform and addressing health equity, to developing innovative approaches to bringing health to all, public/community health nurses throughout decades of practice have built a foundation for modern public health practices. Harriet Tubman, Sojourner Truth, and Lillian Wald are select examples of historical nursing leaders who have advanced public/community health nursing, while Cori Bush and Bonnie Castillo are contemporary nursing trailblazers. While this section includes information about these five exemplary nurses, they represent a fraction of the larger collective of nurses who have advanced client care and population health through numerous professional activities.

THE ROOTS OF HEALTH INEQUITIES

Florence Nightingale

Although nurses around the globe recognize Florence Nightingale as a pivotal figure in shaping modern nursing, her views perpetuated prejudiced, colonial, and classist ideals. In her publications, she demonstrated a belief in the superiority of British people over Indigenous populations. She used these notions to justify the disproportionate rates of death for Indigenous individuals in schools and health-care settings as necessary for societal progress. An alternate version of her *Notes on Nursing* text titled *Notes on Nursing for the Labouring Classes* reinforced exclusionary practices that marginalized individuals based on socioeconomic status.

The legacy of Florence Nightingale is marked by exclusionary and biased ideals, which perpetuate systemic disparities that contribute to contemporary health inequities. Given this context, this chapter will abstain from discussing her professional contributions to public/community health.

(See Bell, 2021; National Commission to Address Racism in Nursing, 2022; Robinson-Lane & Patel, 2022, and Sake-Doucet, 2020.)

Harriet Tubman and Sojourner Truth are often associated with their accomplishments as abolitionists, but they were also enslaved nurses. Although they, along with other Black nurses during the Civil War era, made great contributions to nursing and public health, those contributions are largely disregarded. Sojourner Truth practiced nursing as the private, enslaved nurse for a family in New York ([Figure 3.2](#)) (Painter, 2007). Freed following the state's Emancipation Act of 1827 (Baptiste et al., 2021), she spent the rest of her life advocating for the abolition of slavery, women's rights, humanitarian causes, and funding for nurse training. The U.S. War Department appointed Truth to work as a nurse at Freedman's Hospital in Washington, DC (Davis, 1999). The philosophy underpinning

Truth's practice was the belief that hospitalized clients would not be able to get well in unclean environments (Baptiste et al., 2021). That belief aligns with current public health efforts to promote infection control, clean air, and the importance of environmental factors in maintaining health across the population.

FIGURE 3.2 In addition to advocating for the end of slavery, Sojourner Truth worked as nurse with the National Freedman's Relief Association. (credit: modification of work "Sojourner Truth" by National Portrait Gallery, Smithsonian Institution, Public Domain)

Harriet Tubman was an enslaved nurse who ultimately escaped slavery ([Figure 3.3](#)). Her direct nursing care involved treating injured Black soldiers during the Civil War (Baptiste et al., 2021) and opening a care home for older Black adults in Auburn, New York (Donnelly, 2016; Matthias, 2023). Tubman notably and heroically worked to lead other enslaved people to freedom. Her efforts to fight oppression and promote human rights align with contemporary social justice and equity in access public health priorities (Donnelly, 2016).

FIGURE 3.3 Harriet Tubman provided nursing care to soldiers during the Civil War. (credit: modification of work "Harriet Tubman" by Horatio Seymour Squyer/Wikimedia Commons, Public Domain)

Some consider nurse Lillian Wald ([Figure 3.4](#)) to be the founder of modern public health (Buhler-Wilkerson, 1993). In 1893, she founded the Henry Street Settlement in New York City, which helped members of the public obtain resources such as nursing care in their homes, medicine, food, cab fares, loans, childcare, cleaning, and job training (Pittman, 2019). Wald was also a pioneer in upstream interventions, as she recognized that social reform, more than medical treatments, could bring about great change in health. She was a nurse dedicated to policy reforms to improve workplace conditions, housing, education, and recreation for the public. Lillian Wald believed that people in need must be met where they were, that partnerships between public and private organizations must be forged to support health, and that community resilience must be supported as a means of promoting health (Waters, 2022). These principles may look familiar, as they align with the 10 Essential Public Health Services discussed in [Foundations of Public/Community Health](#) that guide modern public health. The Henry Street Settlement remains in operation in New York City today, addressing the effects of urban poverty and promoting health for many families (Harris, 2019). Wald's groundbreaking and enduring work addressing social determinants of health lives on through the Henry Street Settlement and contemporary public/community health nursing. [Caring Across Practice Settings](#) discusses Wald's work as a public health nurse in more detail.

FIGURE 3.4 Lillian Wald was a public health nurse, social activist, and humanitarian who believed in bringing care and resources to the community. (credit: "Wald, Lillian, Miss" by Harris & Ewing/Library of Congress, No Known Restrictions)

Cori Bush is a member of the U.S. House of Representatives and registered nurse, representing Missouri's first congressional district ([About Cori](#), 2022). Following the murder of Michael Brown in Missouri in 2014 (Associated Press, 2019), she became an influential figure in the local and national movements against police brutality and racial injustices, which inspired her entry into the political arena. Her lived experiences as a Black woman, a mother, being unhoused, surviving assault, working in low-wage jobs that did not support the cost of living, and background as a nurse influence her work and policy positions (Rothberg, 2022). In alignment with the central tenets of public/community health nursing and justice in health care, she supports legislation for a national \$15 minimum wage, tuition-free college, criminal justice reform, and Medicare for All (Adams, 2021; Chávez, 2022, Rothberg, 2022). In 2023, Representative Bush was joined by Lauren Underwood of Illinois as a nurse serving in the U.S. Congress (ANA, 2023). As legislators, nurses are expertly positioned to support legislation that supports the health of the public and advances health equity for the nation.

Bonnie Castillo is a registered nurse and executive director of the largest nurse's union and professional association for registered nurses in the United States, National Nurses United (2023). She has been a leader in promoting health care for all and safety for nurses. In public/community health and beyond, if nurses cannot safely care for clients and communities, population health will not advance. For example, in January 2020, two months before the WHO declared COVID-19 a pandemic, she was already working to determine how prepared the U.S. health system was to

protect nurses and other professionals from the virus (Sharma Rani, 2020). As it turned out, the nation's health system was ill-prepared to protect nurses, as there was a shortage of adequate personal protective equipment (Schlanger, 2020). In response to this shortage, Castillo was one of the first nurse leaders to draw public attention to the personal protective equipment emergency (Huerta, 2020). Beyond her work to support nurses, she was also the director of the [Registered Nurse Response Network \(<https://openstax.org/r/nationalnursesunited>\)](https://openstax.org/r/nationalnursesunited), a professional group that sends registered nurse volunteers to places affected by disasters.

THE ROOTS OF HEALTH INEQUITIES

Misrepresentation in Congress

Given their significant power and influence in the realm of laws and regulations, elected officials play a crucial role in shaping public health policies. Elected officials should represent their constituents—the people who live and vote in their districts. Representation occurs when elected congresspeople support their constituents' interests and needs and ensure that policies align with the health and preferences of those who elected them. One of the ways this representation can be compromised is when a mismatch occurs between the characteristics of constituents and the characteristics of a congressperson or congress at large.

Although diversity within the U.S. Congress has gradually increased over time, it falls short of adequately representing the U.S. population. In 2023, 13 percent of House members were Black, which approximates the percentage of the population that is also Black. However, the number of non-Hispanic White individuals in Congress is disproportionately high. Though non-Hispanic White people make up only 59 percent of the general population, 75 percent of congresspeople are non-Hispanic White (Schaeffer, 2023). Underrepresentation of groups and communities in Congress has implications for health policy decision-making.

At the local level, researchers recently studied the impact of Native American political representation during the COVID-19 pandemic. In places where Native American political representation and political power were more substantial, the number of COVID-19 cases on tribal lands was lower (Evans et al., 2022). Increased political representation can lead to effective and supportive public health policymaking.

Regardless of the national, state, local, or even institutional level, addressing misrepresentation and promoting diversity is a critical element of creating inclusive and equitable public health policies.

(See Evans et al., 2022; Schaeffer, 2023.)

3.2 Public/Community Health Nursing Scope of Practice, Core Competencies, and Function

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 3.2.1 Describe the scope and standards of practice of public/community health nursing.
- 3.2.2 Describe community/public health nursing core competencies.
- 3.2.3 Discuss the knowledge, skills, and attitudes associated with community/public health nursing practice.
- 3.2.4 Identify behaviors reflective of the Quad Council Coalition's community/public health competencies in caring for communities and populations.

Public/community health nursing is a specialty that focuses on improving the health of communities and populations through health promotion, disease prevention, risk reduction, community education, outbreak and epidemic management, and other initiatives. Nurses work in interprofessional teams with clinicians, community members, community partners, and policymakers to support ameliorating health disparities and injustices and ensure equitable access to a healthy life ([Figure 3.5](#)).

FIGURE 3.5 Public/community health nurses can impact health in many ways. Here, U.S. Representative Lauren Underwood speaks at an event celebrating the anniversary of the Family and Medical Leave Act. Underwood is a registered nurse elected to represent Illinois' 14th District in 2019. As such, she has been uniquely positioned to promote public health through national policy and legislation. She has created or supported bills on many health topics, such as mandating the removal of shackles to pregnant incarcerated individuals, ending preventable maternal mortality, climate change, and support for working families. (credit: Alyson Fligg/Department of Labor/Flickr, CC BY 2.0)

Scope of Practice and Practice Standards

The American Nurses Association (ANA) provides a scope of practice and practice standards that guide the current, evidence-based, ethical work of public/community health nurses. Across nursing specialties, such documents or guides are called “scope and standards.” **Scope of practice** refers to the professional activities involved in a particular role. Defining a scope of practice helps nurses work within and to their level of qualification, expertise, and competence. **Standards of practice** are the principles and guidelines to which professionals must adhere. Standards of practice support nurses’ decision-making and delivery of care. Standards can change with the dynamics of the nursing profession and depend on specific contextual factors like clinical situations and circumstances. Nurses across specialties and care settings are expected to be familiar with and adhere to the scope and standards relevant to their professional role.

The ANA identified the following nine core concepts of practice based on the dynamic and complex work of public health nursing:

1. Social determinants of health
2. Community collaboration
3. Population health
4. Ecological model of health: Micro- to macro-levels
5. Culturally congruent practice: Respectful, equitable, and inclusionary
6. Levels of prevention
7. Ethics
8. Social justice
9. Health equity (ANA, 2022)

These principles provide a framework to guide public/community health nurses in practice and support their work in addressing the population’s needs and collaborating with varied parties.

Additionally, the ANA (2022) developed 18 standards of practice and professional performance for public health nursing. The standards for public/community health nursing follow standards set for nurses of any discipline or specialty by the ANA, which describe the who, what, where, when, why, and how of professional nursing practice

(ANA, 2023). The standards of professional public health nursing practice are:

- Assessment: Collects comprehensive data pertinent to the health status of populations.
- Diagnosis: Analyzes the assessment data to determine actual or potential diagnoses, problems, and issues related to health and well-being.
- Outcomes identification: Identifies expected outcomes for a plan specific to the health status of the population or situation.
- Planning: Develops a plan that prescribes strategies to attain optimal health and well-being.
- Implementation: Implements identified plans.
 - Coordination of care: Coordinates care delivery.
 - Health teaching and health promotion: Employs multiple strategies to promote health and safety.
 - Consultation: Provides consultation to enhance the abilities of diverse people to create and effect change.
 - Policy and regulatory activities: Participates in policy and regulatory activities related to health.
- Evaluation: Evaluates progress toward the attainment of goals and outcomes.
- Ethics: Practices ethically.
- Respectful and equitable practice: Practices with cultural sensitivity, humility, and safety in a manner that is congruent with principles of cultural diversity, inclusion, and equity.
- Communication: Communicates effectively in a variety of formats in all areas of practice.
- Collaboration: Collaborates with the population and others in the conduct of nursing practice.
- Leadership: Leads within the professional practice setting and the profession.
- Education: Seeks knowledge and competence that reflect current nursing practice and promote futuristic thinking.
- Evidence-based practice and research: Integrates evidence and research findings into practice.
- Quality of practice: Contributes to quality nursing practice.
- Professional practice appraisal: Evaluates personal nursing practice in relation to professional practice standards, guidelines, and relevant law.
- Resource utilization: Uses appropriate resources to plan and provide nursing and public health services that are safe, effective, and financially responsible.
- Environmental health, planetary health, and environmental justice: Practices in an environmentally safe, fair, and just manner (ANA, 2022).

Using this scope and these standards, public health nurses can help create healthier environments, foster partnerships that promote and protect health, and advocate for justice and health equity in practice.

Core Competencies

Public/community health nurses must possess certain knowledge, skills, and attitudes to effectively fulfill their professional role and successfully meet the community's health needs. In general, nurses need knowledge of epidemiology, environmental health, social determinants of health, statistics, evidence-based practice, health promotion, and factors that impact health. Public/community health nurses need strong communication and relationship-building skills to effectively engage with the community. Attitudes in alignment with social justice, health equity, and advancing health, as well as cultural humility and respect for all community members, are needed to fulfil the roles and responsibilities. Concepts and content related to these professional attitudes are threaded throughout chapters in this text. However, please see [Structural Racism and Systemic Inequities](#), [Designing Culturally and Linguistically Appropriate Programs](#), [Managing the Dynamics of Difference](#), and [Advocating for Population Health](#) for in-depth information. The term **competencies** refers to the foundational knowledge, skills, and attitudes that nurses need to meet their clients' needs. Competencies represent technical skills, personal qualities, and professional behaviors that support successful work in a certain area. In public/community health nursing, four leading nursing organizations formed the Quad Council Coalition in 1988 and collaboratively developed the [Community/Public Health Nursing Competencies](https://openstax.org/r/cphnoorgwp) (<https://openstax.org/r/cphnoorgwp>) in 2018. The Quad Council member organizations include the Alliance of Nurses for Healthy Environments, the Association of Community Health Nurses, the Association of Public Health Nurses, and the American Public Health Association-Public Health Nursing Section (Quad Council Coalition Competency Review Task Force, 2018).

The competencies include major domains and leveled competencies for public/community health nurses to follow

based on their role. Tier 1 competencies apply to nurse generalists who are not in management positions, while tier 2 and 3 competencies are for public/community health nurses who are managers and supervisors or executives, respectively. Applying the domains and competencies of public/community health nursing in professional practice is critical. Public/community health nurses might be the only clinician or care provider some community members have reliable access to, see regularly, or are comfortable talking with. Nurses in community health have a duty to stay abreast of evidence and clinical guidelines that could impact the health and care of the community. [Table 3.1](#) displays the domains, select generalist competencies, and sample public/community health nursing applications to practice associated with each. Please note the table is not exhaustive; see the full Quad Council Coalition document linked above for a comprehensive listing.

Domain	Generalist Competencies	Examples of Nursing Actions
<p>Assessment and Analytic Skills</p> <p><i>Focus on identifying and understanding data, turning data into information for action, assessing needs and assets to address community health needs, developing community health assessments, and using evidence for decision-making</i></p>	<ul style="list-style-type: none"> • Use a data collection plan that incorporates valid and reliable methods and instruments for the collection of qualitative and quantitative data to inform the service for individuals, families, and a community. • Use information technology effectively to collect, analyze, store, and retrieve data related to public health nursing services for individuals, families, and groups. 	<p>Assess for postpartum depression during home visits for new parents using the validated Edinburgh Postnatal Depression Scale. Enter collected data into a secure computer file for analysis.</p>
<p>Policy Development/Program Planning Skills</p> <p><i>Focus on determining needed policies and programs; advocating for policies and programs; planning, implementing, and evaluating policies and programs; developing and implementing strategies for continuous quality improvement; and developing and implementing community health improvement plans and strategic plans</i></p>	<ul style="list-style-type: none"> • Demonstrate knowledge of laws and regulations relevant to public health nursing services. • Comply with organizational procedures and policies. 	<p>Review the local nurse practice act, public health nursing scope and standards of practice, job description, and relevant employer policies regularly.</p>

TABLE 3.1 Community Health Nursing Competencies

Domain	Generalist Competencies	Examples of Nursing Actions
<p>Communication Skills <i>Focus on assessing and addressing population literacy; soliciting and using community input; communicating data and information; facilitating communications; and communicating the roles of government, health care, and others</i></p>	<ul style="list-style-type: none"> Apply critical thinking and cultural awareness to all communication modes (i.e., verbal, nonverbal, written, and electronic) with individuals, the community, and other parties. Use various methods to disseminate public health information to individuals, families, and groups within a population. 	<ul style="list-style-type: none"> Listen attentively to community member reports of health and demonstrate empathy and compassion in conversation. Prepare health information for distribution via printed flyers, website posting, and email blasts.
<p>Cultural Competency Skills <i>Focus on understanding and responding to diverse needs, assessing organizational cultural diversity and competence, assessing effects of policies and programs on different populations, and taking action to support a diverse public health workforce</i></p>	<ul style="list-style-type: none"> Deliver culturally responsive public health nursing services for individuals, families, and groups. Explain the benefits of a diverse public health workforce that supports a just and civil culture. 	<ul style="list-style-type: none"> Ensure health recommendations and suggestions for community participation align with cultural needs; for example, avoid suggesting attending community events that occur during religious holidays. Support the hiring of colleagues that ensures the characteristics and demographics of the workforce approximate the community.
<p>Community Dimensions of Practice Skills <i>Focus on evaluating and developing linkages and relationships within the community, maintaining and advancing partnerships and community involvement, negotiating for the use of community assets, defending public health policies and programs, and evaluating & improving the effectiveness of community engagement</i></p>	<ul style="list-style-type: none"> Assist individuals, families, and groups in identifying and accessing necessary community resources or services through the referral and follow-up process. Build preferences into public health services. 	<ul style="list-style-type: none"> Remain aware of all community agencies, events, programs, and opportunities for social prescribing. Evaluate client, family, and community comfort level and agreement with participating in selected activities.

TABLE 3.1 Community Health Nursing Competencies

Domain	Generalist Competencies	Examples of Nursing Actions
<p>Public Health Sciences Skills <i>Focus on understanding the foundation and prominent events of public health, applying public sciences to practice, critiquing and developing research, using evidence when developing policies and programs, and establishing academic partnerships</i></p>	<ul style="list-style-type: none"> Assess hazards and threats to individuals, families, and populations and reduce their risk of exposure and injury in natural and built environments (i.e., chemicals and products). Model public health science skills when working with individuals, families, and groups. 	<ul style="list-style-type: none"> Observe for methods of cleaning products and other household chemical storage during a pediatric home visit. Guide practices with evidence-based resources obtained from the scholarly literature and guidelines of reputable organizations.
<p>Financial Planning, Evaluation, and Management Skills <i>Focus on engaging other government agencies that can address community health needs, leveraging public health and health care funding mechanisms, developing and defending budgets, motivating personnel, evaluating and improving program and organization performance, and establishing and using performance management systems to improve organization performance</i></p>	<ul style="list-style-type: none"> Interpret the impact of budget constraints on the delivery of public health nursing services to individuals, families, and groups. Organize public health nursing services and programs for individuals, families, and groups within budgetary guidelines. 	<ul style="list-style-type: none"> Periodically review the out-of-pocket cost and health plan coverage of interventions suggested to clients and families. Prioritize free or low-cost recommendations for health promotion and risk reduction activities.
<p>Leadership and Systems Thinking Skills <i>Focus on incorporating ethical standards into the organization; creating opportunities for collaboration among public health, health care, and other organizations; mentoring personnel; adjusting practice to address changing needs and environment; ensuring continuous quality improvement; managing organizational change; and advocating for the role of governmental public health</i></p>	<ul style="list-style-type: none"> Apply systems thinking to public health nursing practice with individuals, families, and groups. Model personal commitment to lifelong learning, professional development, and advocacy. 	<ul style="list-style-type: none"> Recognize the role and utility of health services across the care continuum. Engage in continuing education opportunities relevant to the needs of the community served.

TABLE 3.1 Community Health Nursing Competencies

Public/community health nurses have a vital role in meeting the health needs of a community. Their expertise in epidemiology, environmental health, social determinants, statistics, evidence-based practices, and health promotion impacts the communities they serve and the greater population. These nurses build relationships with community members and local agencies to make appropriate connections and referrals in support of health. Nurses in this area must guide their professional practices with a social justice lens, recognizing that health disparities and inequities in communities exist and influence health. The Community/Public Health Nursing Competencies provide a

framework for nurses in community health to follow to meet the needs of the community holistically.

3.3 Public/Community Health Nursing Practice

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 3.3.1 Identify how the public health system interfaces with nursing care.
- 3.3.2 Explain the nurse's role in public/community health.
- 3.3.3 Describe how public/community health nurses facilitate the core functions of public health.
- 3.3.4 Explain why public/community health nursing is essential to promoting and protecting the health of communities.

Using the Community/Public Health Nursing Competencies as a guide, nurses in this specialty significantly impact the health of populations. Public/community health nurses collaborate with clinicians across the care continuum to bridge the gap between care that is offered or available and care that is needed or accessed. Health promotion and education, social prescribing, community assessments, advocacy, and disease and disaster response are several examples of essential public/community health nursing interventions that promote and protect the health of community members.

Interface of Public Health with Nursing Care

Public health and clinical care can interact on a daily basis to support health across populations of clients. Some interactions are more visible than others, such as during times of a global pandemic. Despite increases in the visibility of and focus on public health during the COVID-19 pandemic, collaborations between public health and clinical care have been longstanding and ongoing. Such collaborations support both communicable and noncommunicable health concerns.

During the COVID-19 pandemic, public health efforts such as global, national, county, or city-specific disease surveillance and reporting played a crucial role in guiding clinical care decisions. Such efforts helped hospitals and other care facilities predict the need for services, directed policies on physical distancing and whether businesses and other community centers were open to the public, and helped clients and families evaluate the risk of socializing with those from other households. Public health efforts such as requiring masks when in public helped individuals, families, and essential workers avoid spreading or contracting COVID-19 (Cowger et al., 2022; Kocolek et al., 2022). Places that implemented public health policies to facilitate distancing, such as mandating quarantine and isolation when ill, school closures, household confinement, and limiting social gatherings, coincided with fewer COVID-19 cases and lower disease transmission rates than in places that did not implement such procedures early or stringently (Zweig et al., 2021). As public health efforts in prevention, screening, and later vaccination aimed to reduce the clinical care needed across the globe, clinical care efforts were supported by public health initiatives ([Figure 3.6](#)). Clinical care included treatment of active infection, but also testing and diagnosis in established care centers and drive-through operations. Public health efforts also supported the availability of needed medications, supplies, and equipment to treat active infections in hospitals and homes. Once a vaccine was developed, clinical care included vaccine administration. At the same time, public health initiatives determined priority groups for vaccination, established vaccine clinics across communities, and promoted vaccines as a method of health promotion and disease control.

FIGURE 3.6 A public health worker in Hawaii distributes at-home COVID-19 testing kits at a drive-through distribution event in March of 2022. Throughout the COVID-19 pandemic, public health organizations across the globe orchestrated accessible, convenient, and safe drive-through events for obtaining point-of-care COVID-19 testing, vaccines, and home test kits. (credit: Navy Medicine/Flickr, Public Domain)

Infectious disease response and control presents an opportunity for public/community health frameworks to guide clinical care and for nursing care to support public/community health goals. However, public/community health and nursing care also work in concert to address noncommunicable diseases and health concerns. Addressing the population's mental health is a key example. Mental health impacts people of all genders, races, ages, occupations, parenting status, and education levels. In fact, 25 percent of youth experience depressive symptoms, 35 percent of adults aged 45 years and older feel lonely, and the suicide rate among all nurses is 18 percent higher than the U.S. general population, with female nurses having twice the risk of dying by suicide than the general population (Blazer, 2020; Lee and Friese, 2021; Office of the Surgeon General [OSG], 2021). Public health agencies may develop promotional campaigns to reduce the stigma surrounding mental health disorders and educate the public on signs that indicate help is needed for a mental health concern. Clinicians provide comprehensive mental health care that can include similar education personalized for the client. Public health agencies may work with clinicians to implement standard mental health screening tools into every preventative health encounter and then provide referral sites where other clinicians can offer expert mental health care and counseling. Clinicians may also engage in public health data sharing, making relevant public health agencies and organizations aware of the rates of mental health concerns in a community or nationally. Such sharing supports proper funding of programs to support mental health for all and treat mental illness among affected clients.

WHY ARE EVERYDAY INJURIES A PUBLIC HEALTH ISSUE?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/3-3-publiccommunity-health-nursing-practice>\)](https://openstax.org/books/population-health/pages/3-3-publiccommunity-health-nursing-practice)

In this video, Dr. Deboki Chakravarti of the American Public Health Association (APHA) shares information about unintentional injuries as a public health issue. Unintentional injuries are another example of a non-communicable category that presents an opportunity for public health and clinical care to interact.

Watch the video, and then respond to the following questions.

1. Dr. Chakravarti shares information about public health initiatives aimed at addressing injuries across age groups. She discusses unsafe sleeping conditions for infants, drowning for young children, car accidents for teens, and workplace injuries for adults. What are some components of clinical care that work in concert

- with public health interventions to address these accidents?
2. Since the video has been published, new evidence has emerged that names gun violence as the leading cause of death in children (Goldstick et al., 2022). Can you think of the public health and clinical care interventions that can address this public health crisis?

Remember that efforts across clinical and health areas might address upstream or downstream factors. As discussed in [What Is Population Health?](#) upstream factors involve actions and initiatives that address the root causes of health issues, whereas downstream factors include responses to health issues without focusing on solving or preventing the health problem. Thinking about how to create meaningful change in upstream factors can be overwhelming and is much more labor-intensive than, say, teaching a client about the safe administration of medications. Importantly, it is not the responsibility of *one* nurse to change upstream factors or to move an entire health system to a focus on prevention over treatment. Working with individual clients who have diagnosed conditions is, of course, important to their health and quality of life and is a duty of nurses. However, nurses also have a duty to support meaningful upstream change for their clients and the community at large. Nurses can contribute to advancing this area through advocacy and activism, which are detailed in [Advocating for Population Health](#). Nurses are well positioned, and have a professional duty, to leverage their personal, social, and political capital (Florell, 2021) as members of a highly trusted profession to engage in nursing activism and advance health equity through upstream change.

The Role and Significance of the Community Health Nurse

As frontline clinicians on whom community members rely for health care and guidance, public/community health nurses play a crucial role in sharing health information, promoting health through education and counseling, and implementing preventative care activities. Public/community health nurses meet the needs of community members seeking health guidance and health care through several key roles and responsibilities.

Health Promotion and Education

Public/community health nurses educate clients, families, and communities on health topics and conditions, preventative measures, and approaches to wellness. For example, nurses in this specialty may teach caregivers of toddlers about nutrient-dense foods that picky eaters may enjoy or hold a weekly session to help seniors on a fixed income create recipes based on the local grocery store's weekly sale flyer. Nurses may employ many teaching methods, including conducting live and in-person class sessions, holding Zoom meetings, or distributing printed material. Nurses can create their own teaching material informed by current research, best practices, or clinical guidelines or may access freely available toolkits. Toolkits are often developed by health departments, colleges and universities, or national health organizations. For example, teaching toolkits are available for [HPV vaccination](#) (<https://openstax.org/r/jhforgadmin>), [substance-use prevention](#) (<https://openstax.org/r/preventionab>), [healthy sleep](#) (<https://openstax.org/r/sleepeducation>), [hypertension](#) (<https://openstax.org/r/heartorgenh>), [interpreting nutrition labels](#) (<https://openstax.org/r/fdanutritioneducati>), and many other health topics.

Health promotion efforts also involve screening for conditions and diseases so that the public/community health nurse can make appropriate and early referrals for care. A nurse may offer monthly vision and hearing screenings to alert community members to the need for sensory aids. Preventing diseases before they occur through education and other health promotion activities helps communities reduce disease prevalence, incidence, and impact. This is important for the health of the population but also decreases the burden and spending on the health care system and resources of the community. In fact, one study of a nurse-led community-based clinic in which clients could receive nonurgent health care and guidance demonstrated a \$34 savings to society for every \$1 invested (Bicki et al., 2013). While there is some rhetoric regarding the utility and cost of nurse-led clinics, a comprehensive review determined that these clinics do not increase health care costs and have improved client satisfaction with and access to health services (Connolly & Cotter, 2023). Ongoing rigorous research regarding the role of nurse-led initiatives is needed to reach additional conclusions regarding their impact on population health.

Social Prescribing

Social prescribing involves referrals to community resources other than those traditionally considered directly related to the health care setting. Social prescribing is a cost-effective way to support clients and families with chronic conditions with symptom management and health promotion (Husk et al., 2020). Public/community health

nurses may facilitate connections to community agencies that support health and social needs, such as financial planning, a walking group, or a community garden ([Figure 3.7](#)). Activities like ballroom dancing, volunteering, seeing plays, or visiting museums can benefit clients' emotional health, social connectedness, and feelings of empowerment (Chen, 2022). Social prescribing interventions can engage the diverse population in social and health-promoting experiences that also decrease utilization of formal health care services and prevent development of chronic conditions (Howarth et al., 2020). To learn more about this topic, watch the video [What is social prescribing? \(<https://openstax.org/r/socialpresc>\)](#).

FIGURE 3.7 Clarence Webb proudly displays a bunch of kale grown at the community garden *Grow Dat Youth Farm* in New Orleans. Community members who learn to grow food here have opportunities to explore and practice sustainable agriculture, engage in community leadership, and support food security and food justice. Referrals to community agencies like community gardens go beyond the conventional boundaries of nursing care and exemplify the concept of social prescribing. (credit: Kirsten Strough/USDA/Flickr, Public Domain)

HEALTHY PEOPLE 2030

Food Insecurity

[Food insecurity \(<https://openstax.org/r/healthypeoplep>\)](#) refers to limited or uncertain access to food. Income, employment, race/ethnicity, and disability may all be contributing factors. Neighborhood access to grocery stores impacts food security, given the limited options and higher prices at smaller convenience stores. Additionally, lack of personal transportation or access to public transportation to travel to a faraway grocery stores can precipitate food insecurity. The Healthy People 2030 program aims to reduce household food insecurity and hunger, eliminate very low food security in children, and increase the consumption of fruits and vegetables among people ages 2 and older.

Community Assessments

Nurses in community health can assess communities or groups within communities to determine health problems, health risks, and the need for teaching or other interventions. [Creating a Healthy Community](#) describes community assessments in depth. Community assessments can also reveal problems or areas of opportunity related to health equity. Nurses in community health address health disparities, promote equity, and facilitate justice.

Health Advocacy

Using results of community assessments and professional experiences with addressing the health needs of the community, the public/community health nurse can advocate for services and programming that the community needs to achieve health. Additionally, public/community health nurses can engage in proactive advocacy. Public/

community health nurses participate in safeguarding (e.g., tracking medical errors), empower clients and families with information about their health condition and possible alternatives to care plans, liaise between families and providers, and champion social justice (Abbasinia et al., 2020). [Advocating for Population Health](#) discusses the nurse's role as advocate in depth.

CASE REFLECTION

Health Education, Social Prescribing, and Health Advocacy

Read the scenario, and then respond to the questions that follow.

As you have gotten to know the Lee family, you have also improved your public/community health nursing skills. You are interested in employing health education, social prescribing, and health advocacy in your professional role to address some of the health concerns of the Lee Family.

1. What health advocacy could you conduct to address the Lee family's lack of access to clean water?
 2. What health education could you provide, and to whom, to support Sunshine's safety given her life-threatening allergy?
 3. What social prescriptions might you make to the entire family?
-

Disease and Disaster Response

Public/community health nurses prevent the spread of diseases across communities through the following by:

- Administering immunizations
- Screening for infectious and communicable diseases
- Providing education on infection control
- Educating community members on disease mitigation and self-assessments

Public/community health nurses are at the forefront of response efforts during natural disasters, mass casualty incidents, and other crises. These nurses provide immediate, on-site care to those affected physically and emotionally by disasters. They also coordinate resources, connect community members to needed resources, and support those affected in efforts to rebuild or return to predisaster levels of functioning. Importantly, public/community health nurses collaborate with public services (e.g., police and fire) to develop plans for responding to disasters in the community. Addressing disasters and engaging in disaster planning helps the public/community health nurse build community resilience. Through building confidence in the community's ability to respond to a disaster, creating networks of support, and expertly managing health needs in an evolving situation, these nurses minimize the negative health impact of actual or potential disasters.

The professional services public/community health nurses offer and roles they fill are essential to promote and protect the health of communities. Such nursing efforts largely focus on prevention and early intervention to address health issues before they develop or contribute to disability and decreases in quality of life. With a focus on prevention and health promotion rather than reacting to diagnoses, public/community health nurses can empower individuals, families, and communities to make informed decisions about health and be involved in their own care and needs. Through assessments and related advocacy, nurses facilitate additional community empowerment, as community members may be involved in local health decision-making processes and be invested in participating in health programming. Finally, emergencies, disasters, and disease outbreaks significantly compromise a community's health. Public/community health nurses establish response plans, coordinate and mobilize resources during a disaster, and ensure that resources needed to stay safe and healthy are available in times of crisis ([Figure 3.8](#)). [Principles of Disaster Management](#) discusses this topic in more detail.

FIGURE 3.8 A community health worker distributes water, diapers, personal care products, and other essential supplies to community members of St. John, USVI, following a natural disaster. Resource management and supply distribution following natural disasters such as floods, fires, and hurricanes pose significant challenges due to co-occurring infrastructure collapse and logistical constraints. Public/community health nurses can manage and organize the distribution of medical and essential supplies and ensure equitable distribution of resources following a disaster. (credit: Jocelyn Augustino/FEMA/Flickr, Public Domain)

Public/Community Health Foundations and Nursing Practice

Nurses provide services to clients, families, groups of people, and the larger community in a specific place. The place may be a school or school district, health center, prison, or memory care facility, as only a few examples. Public/community health nurses may set goals related to each of the essential services and core functions, implement interventions, and lead aspects of care in the community to meet the public's health needs and broad population health goals. They provide direct care, education, and assessments and fill other duties to promote health, prevent disease, reduce risk, and support the health of the determined community. Regardless of the activity or step of the nursing process addressed, providing care to communities, and not just in the community, is an important consideration when thinking about what role a nurse may be filling. To provide care to the community, public/community health nurses guide their practice with the core functions of public health, the 10 Essential Public Health Services, and the levels of prevention.

[Foundations of Public/Community Health](#) discussed the [10 Essential Public Health Services \(<https://openstax.org/r/publichealthgatewaya>\)](https://openstax.org/r/publichealthgatewaya) that all communities should use to protect and promote health in communities. The core functions of public health are carried out via these activities. [Table 3.2](#) connects the 10 Essential Public Health Services with an exemplar regarding public/community health nursing care supporting children's dental health.

Essential Public Health Service	Example Supporting Dental Health in Children
1. Assess and monitor population health status, factors that influence health, and community needs and assets	A public/community health nurse receives a report from a school nurse that many elementary-school children have obvious and painful dental caries. They collect data on the number of dental offices in the county, the cost of attending a dental appointment, and methods of accessing the dental offices. They also collaborate with the school nurse to identify any dental education efforts in the school setting.
2. Investigate, diagnose, and address health problems and hazards affecting the population	The public/community health nurse determines that there are only two dental offices in the county that provide care to children, a visit costs 30 percent of the average weekly salary for families, and public transportation options to access the dental offices are limited. The school has limited education on healthy teeth, brushing, and flossing for first-grade students. The nurse has identified issues in access to dental care for children and preventive teaching and will work to address these gaps in health care.
3. Communicate effectively to inform and educate people about health, factors that influence it, and how to improve it	The public/community health nurse discusses methods of increasing dental health education in the school with the school nurse, teachers, and principals. They use funds available to purchase a toothbrush, toothpaste, and flossers for every child in the county elementary schools. They collaborate with the school team to develop a short video and flyer for parents about dental health in children.
4. Strengthen, support, and mobilize communities and partnerships to improve health	The public/community health nurse builds a relationship with the dental offices in the county to determine the feasibility of offering dental services to the children while at school.
5. Create, champion, and implement policies, plans, and laws that impact health	The public/community health nurse communicates findings about unaddressed dental caries in children to the county and state lawmakers. They propose a funding initiative to subsidize the cost of dental visits for children to the two offices offering pediatric services and funding for a mobile dental unit that could visit each school once per month to carry out dental exams and fillings.
6. Utilize legal and regulatory actions designed to improve and protect the public's health	The public/community health nurse contacts the county water department to ensure that water is being adequately fluoridated per state law.
7. Assure an effective system that enables equitable access to the individual services and care needed to be healthy	The public/community health nurse files a formal request with the public transportation bus unit to develop additional routes that include stops proximal to the dental offices so families without reliable transportation may access the dental office.

TABLE 3.2 Ten Essential Public Health Services Related to Public/Community Health Nursing Care

Essential Public Health Service	Example Supporting Dental Health in Children
8. Build and support a diverse and skilled public health workforce	The public/community health nurse involves community members with diversity in experiences, gender, race, and dental health history by recruiting older students from the high school to serve as interns three hours per week to mentor the elementary-school students on dental care.
9. Improve and innovate public health functions through ongoing evaluation, research, and continuous quality improvement	The public/community health nurse collects data on the number of children evaluated and treated in the mobile dental van and increases in dental office visits with the newly added bus routes. They determine that the new bus routes are underutilized for dental office visits, so they request public funds be re-allocated from the new bus routes to funding additional dental van days at each elementary school.
10. Build and maintain a strong organizational infrastructure for public health	The public/community health nurse will maintain and develop new partnerships with dental and health-focused organizations in the county and beyond and will continue to collect data to support the ongoing need for supplies and funding to ensure dental caries are prevented, identified, and addressed in elementary-school children.

TABLE 3.2 Ten Essential Public Health Services Related to Public/Community Health Nursing Care

HEALTHY PEOPLE 2030

Increase the proportion of children and adolescents who have dental sealants on 1 or more molars

Healthy People 2030 has set a goal to [increase the proportion of children and adolescents \(https://openstax.org/r/healthypeopleoba\)](https://openstax.org/r/healthypeopleoba) who have received dental sealants on one or more primary or permanent molar teeth.

Dental sealants are coatings that are painted on teeth and can prevent tooth decay. This preventive intervention can help children avoid cavities for years. School-based dental programs are one way to ensure all children have access to dental sealant regardless of race/ethnicity or income, two determinants with noted disparities in access to this component of care.

Thinking back to [Foundations of Public/Community Health](#), recall that the essential services align with the [three core functions of public health \(https://openstax.org/r/malphorgsitea\)](#): assessment, policy development, and assurance. Please see [Table 3.3](#) for examples of how community/public health nurses implement the core functions of public health across a variety concerns and conditions affecting the health of the public.

Topic	Assessment Collecting and analyzing data to:	Policy Development Collaborating with local legislators, businesses, schools, and other organizations on policies supporting:	Assurance Providing:
Asthma	Identify the prevalence of asthma, common triggers, and temporal patterns in exacerbations	Asthma-friendly environments and improved air quality	Hands-on teaching regarding the use of asthma medications and devices

TABLE 3.3 Public/Community Health Nursing Implementation by Core Function

Sexually transmitted infections (STIs)	Determine STI rates, high-risk populations, and trends in transmission	Access to confidential and affordable testing and treatment	Education and counseling on prevention and treatment, confidential partner notification and contact tracing
Headache disorders	Describe the prevalence and impact of headache disorders	Headache-friendly workplaces and school/work attendance flexibility	Support groups for community members with chronic headache disorders
Diabetes	Identify community members at risk for diabetes	Affordable access to diabetes supplies, exercise, and nutrient-dense foods	Self-management education programs
Food safety	Evaluate food-handling practices of local restaurants and eateries	Food safety training and outbreak prevention	Guidance and case triage of community members impacted by an outbreak
Violence	Explore the availability and content of violence prevention programs and resources	Gun-safety legislation and trauma-informed care practices	Support and counseling for those affected by community violence
Immunization	Monitor immunization rates among community members	Vaccine requirements for school attendance	Immunization clinics and health promotion education regarding vaccine uptake

TABLE 3.3 Public/Community Health Nursing Implementation by Core Function

Public/community health nursing activities can be categorized by the five levels of prevention below. [Foundations of Public/Community Health](#) provides more details on each level.

- Primordial prevention
- Primary prevention
- Secondary prevention
- Tertiary prevention
- Quaternary prevention

[Table 3.4](#) provides examples of nursing activities across the levels of prevention and related activities that support the core functions of public health. Because quaternary prevention concerns what public/community health nurses and other professionals should avoid (Martins et al., 2018), this level is not included in the table.

Topic	Primordial	Primary	Secondary	Tertiary
Cardiac health in older adults	Implements community programming that promotes good general health, such as physical activity and stress reduction	Leads a fitness walking group for attendees of the senior center without cardiac health conditions	Conducts weekly blood pressure screenings for seniors	Leads a fitness walking group for attendees of the senior center with cardiac health conditions
Teen pregnancy	Provides mandated comprehensive sex education programs to all students in grades 9 to 12	Facilitates access to barrier methods of contraception in schools and additional contraceptive services at the local health clinic	Offers pregnancy testing and prenatal counseling to teens	Delivers quarterly parenting and child development seminars for pregnant teens and partners
Seasonal influenza	Implements public awareness campaigns regarding handwashing and respiratory hygiene	Administers influenza vaccines each fall to students enrolled in city schools	Provides accessible testing to facilitate early diagnosis	Counsels ill individuals on supportive care measures and facilitates access to antiviral medications as appropriate
Smoking cessation	Enforces comprehensive tobacco control policies	Educes community members on the health risks and implications of smoking	Provides individual and group counseling to smokers	Offers relapse prevention services for community members who have successfully quit
Road accidents	Supports legislation for clearly designated bike lanes and crosswalks	Teaches young children about walking and pedestrian safety	Coordinates efficient systems for rapid emergency services responses to scenes of accidents	Ensures community access to rehabilitative services following a road accident
Suicidality	Promotes mental health awareness and antistigma education	Trains caregivers, teachers, and other community members on suicide prevention and intervention techniques	Establishes community crisis hotlines	Coordinates support groups for individuals and families affected by suicide
Substance use disorder	Develops mandate for prescribers in community to engage in safe prescribing practices education	Educating community members on healthy coping skills	Provides screening and referral for middle and high school students	Facilitates access to prescribers of medication-assisted treatment as a recovery support

TABLE 3.4 Public/Community Health Activities

Health Across the Community Helps Clients and Families

Public/community health nurses may work in specialty roles as school nurses, street nurses, occupational health nurses, home care nurses, correctional nurses, or clinic nurses. [Caring Across Practice Settings](#) describes several of these nursing roles. Nurses in public/community health provide direct-care services, promote health, reduce risk, and prevent disease within communities. They apply the nursing process to identify the community's health needs,

create and disseminate interventions, engage in advocacy efforts, and collaborate with community members to support the overall health of the community. These nurses provide the care and services that support population health goals in the community.

Note that the term “community nurse” may have a different meaning globally. For example, outside of the United States “community nurse” or “district nurse” may refer to nurses who provide direct care in client homes.

Public/community health nurses apply a community-focused lens to their professional practice. This lens provides a broader view of health and captures more of the community members in their professional efforts. Their work will involve promoting public health practices and preventing disease among large groups, such as those in schools, prisons, or community care centers. [Table 3.5](#) provides examples of public/community health nurse care settings and nursing actions performed. Additionally, the [Johnson & Johnson Nursing website \(<https://openstax.org/r/nursingjnj>\)](https://openstax.org/r/nursingjnj) details 96 different nursing specialties, many of which are community-based.

Setting/Specialty	Example of Actions Performed
School	<ul style="list-style-type: none"> • Assess student episodic health concerns • Manage student chronic conditions • Conduct vaccine surveillance
Corrections	<ul style="list-style-type: none"> • Evaluate client response to treatment • Educate clients on chronic disease self-management • Promote infection control practices among clients and staff
Camp	<ul style="list-style-type: none"> • Provide camper and staff first aid • Educate campers and staff about sun safety • Securely store emergency medications and develop administration procedures
Occupational health	<ul style="list-style-type: none"> • Evaluate work environments for health risk • Develop accident or disaster response plans • Assess and treat employee injuries
Home health—continuous services	<ul style="list-style-type: none"> • Provide round-the-clock care to a client so they may live in their home instead of an inpatient setting • Facilitate client access to their community • Periodically evaluate the need for continued continuous services
Home health—skilled visits	<ul style="list-style-type: none"> • Administer injections or infusions in the home setting • Educate clients and families about home management of health conditions • Manage complex client wounds
Hospice	<ul style="list-style-type: none"> • Manage client pain and symptoms at end of life • Provide psychosocial support and coping counseling to the client and family • Educate client and family members of expected course of care
Parish/faith	<ul style="list-style-type: none"> • Initiate health and wellness programs for a faith community • Connect clients and families to local health resources • Visit faith community members’ homes or hospital rooms when ill
Ambulatory care	<ul style="list-style-type: none"> • Assess client and family general health • Collaborate with clients to determine plans for supporting wellness • Create client and family care plans

TABLE 3.5 Community Health Nursing Specialties and Actions

While the community is the client, individuals and families can be recipients of care. Public/community health nurses also provide direct care to individuals and families outside of acute-care centers, such as in personal homes

and clinics. Individuals and families may need direct nursing care and support to address their conditions and personalized health concerns. Public/community health nurses help individuals and families learn to manage conditions and can administer ordered care and treatments.

When a public/community health nurse cares for a client, family, or group, the benefits of such care extend to the community at large. The individual or family benefit from direct nursing care; and the community at large may experience reductions in communicable diseases, amelioration of health care disparities, lowered health care costs, and other benefits. To address health needs in the community, public/community health nurses may mobilize existing resources or develop new programs that will benefit clients and families across the community. They work with community members to determine their health priorities and align programs and initiatives with the community's needs. This requires analysis of community member input and community-level health data.

WHAT IS A COMMUNITY/PUBLIC HEALTH NURSE?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/3-3-publiccommunity-health-nursing-practice>\)](https://openstax.org/books/population-health/pages/3-3-publiccommunity-health-nursing-practice)

This video follows a nurse as she contemplates different ways to contribute to health and well-being via roles in community health. Community-based and hospital-based nurses can collaborate and serve equally important roles in bridging client transitions across the care continuum to ensure safe and supportive care.

Watch the video and visit the [Johnson & Johnson \(<https://openstax.org/r/nursingjna>\)](https://openstax.org/r/nursingjna) nursing specialty website, and then respond to the following questions.

1. Thinking about the Lee family, which community health nursing roles or specialties could help promote health and reduce risk for the family?
2. What kinds of community health nursing jobs or roles are of interest to you in the future?

Chapter Summary

3.1 Defining Public/Community Health Nursing

Community health focuses on the physical, mental, and social well-being of a community. Nurses promote health, prevent diseases, and address the needs of populations with shared characteristics, health conditions, and health risks. Public/community health nurses have a rich history of service. Events such as World War II, the HIV and AIDS epidemic, and the COVID-19 pandemic were greatly impacted by nursing and have shaped modern public/community health nursing practice. Nursing leaders have contributed to this field by addressing social determinants and inequities and by caring for vulnerable populations.

3.2 Public/Community Health Nursing Scope of Practice, Core Competencies, and Function

Nurses in public/community health work in

Key Terms

community a group of people with at least one characteristic in common

community health the physical, mental, and social well-being of a community; involves health promotion, risk reduction, and disease prevention

community/public health nursing specialty focused on improving the health of communities and populations through health promotion, disease prevention, risk reduction, community education, management of outbreaks and epidemics, and other initiatives

competencies foundational knowledge, skills, and attitudes that enable nurses to meet client needs

contact tracing identification of people who may

have been exposed to a specific disease and are at risk for disease acquisition or spread

disease surveillance data-collection activities that aim to inform a disease response plan

scope of practice professional activities involved in a particular role; supports nurses working to their level of qualification, expertise, and competence

social prescribing referrals to community resources outside of traditional health care settings

standards of practice rules of conduct to which professionals are expected to adhere; support nurses' decision making and delivery of care

vaccine uptake the proportion of the population receiving a vaccination

Review Questions

- Which action by the nurse demonstrates the application of community health principles to a program aimed at preventing cardiovascular disease through risk-factor modification?
 - Providing individual counseling sessions for adults at risk for heart disease
 - Promoting a weekly farmer's market for locally grown fruits and vegetables
 - Assisting an adult with heart disease to develop a medication schedule that fits their lifestyle
 - Developing a cardiac rehabilitation program for community members with heart failure
- Which nursing action following World War II represents an autonomous public-health nursing function?
 - Providing direct care to wounded soldiers in military hospitals
 - Conducting vaccination campaigns to promote immunizations
 - Collaborating with physicians to perform medical procedures
 - Assisting in surgical operations in field hospitals
- Which statement describes the purpose of defining a scope of practice for nurses?

- a. Establishing principles and guidelines for professional behaviors and ethics
 - b. Outlining specific clinical skills and procedures nurses may perform
 - c. Ensuring nurses work within their level of qualification, expertise, and competence
 - d. Promoting collaboration in teamwork within a health care setting
- 4.** Which of the following accurately describes public health nursing practice?
- a. The scope of practice for public health nurses is broader than that of a registered nurse.
 - b. The ANA has identified nine core concepts for public health nursing.
 - c. Public health nurses practice using standards developed for medicine.
 - d. The ANA has not identified a scope of practice for public health nursing.
- 5.** Which action by the public health nurse is an example of the “public health sciences” domain of the Quad Council Coalition’s Community/Public Health Nursing Competencies?
- a. Recommending a walking trail to encourage wellness
 - b. Providing educational materials that meet the community’s cultural needs
 - c. Applying research findings to the development of new community programs
 - d. Assisting families in finding affordable health insurance
- 6.** Which Quad Council Coalition’s Community/Public Health Nursing Competency domain is the nurse engaged in when hiring a workforce representative of the community?
- a. Communication
 - b. Cultural competency
 - c. Community dimensions of practice
 - d. Leadership and systems thinking
- 7.** Which action by the community health nurse is an example of a downstream intervention?
- a. Focusing on health promotion and disease-prevention activities
 - b. Managing the care of clients diagnosed with health conditions
 - c. Engaging in advocacy and activism to advance health equity
 - d. Addressing the root causes of health problems in a population
- 8.** Which action will the community health nurse take when engaged in the activity of social prescribing?
- a. Referring a client with heart failure to a cardiac rehabilitation program
 - b. Teaching a client with a new diagnosis of diabetes how to inject insulin
 - c. Suggesting volunteer work to a client who is feeling depressed after retiring
 - d. Assessing the social resources of a community
- 9.** The community health nurse is interviewed for a podcast to discuss bike safety tips for children. Which level of prevention is the community health nurse providing during the interview?
- a. Primordial
 - b. Primary
 - c. Secondary
 - d. Tertiary
- 10.** Which activity will the community health nurse perform when engaged in secondary prevention activities at a community senior center?
- a. Educating about signs and symptoms of influenza
 - b. Administering pneumococcal pneumonia vaccines
 - c. Providing information about supportive care for COVID-19
 - d. Teaching how to properly wash hands

CHAPTER 4

The Health of the Population

FIGURE 4.1 The concept of what it means to be healthy is different for everyone. The role of the population health nurse is to support clients as they strive to attain positive health outcomes. (credit: modification of work “Start of Tullamore Half Marathon 2014” by Peter Mooney/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 4.1 Defining Health
- 4.2 Performance Metrics
- 4.3 Health in America
- 4.4 World Health Statistics
- 4.5 Global Public Health Security

INTRODUCTION Sara, an 18-year-old mother, brings her infant, Jasper, to the rural health clinic for his 2-month checkup. Nurse Mateo notes that Jasper is due to receive several vaccinations. He begins explaining their purpose to Sara and gives her an immunization schedule for a child’s first year. Sara frowns and seems reluctant to take the schedule; she says, “Jasper has already had lots of shots,” and she wonders about how well vaccinations even work since her father “still got COVID-19 even though he was boosted.” Mateo, understanding this is an opportunity to educate the new parent on illness prevention, begins describing the different childhood diseases that are now preventable by immunizations. Using parent-friendly handouts from the Centers for Disease Control and Prevention (CDC), he discusses issues that may occur when an unimmunized child attends day care or school or socializes with other children, along with the possible consequences of not receiving the recommended vaccinations. No longer frowning, Sara nods and follows along as Mateo points out the different vaccinations on the handout.

Clinic visits like this one are opportunities for clients to obtain information on keeping themselves and their families healthy and free from illness. Providing education on preventive care is one example of how nurses work in the community. Nurses like Mateo must understand the health needs of their communities to enhance health. This

chapter explores the health needs of a population by defining health, describing the current health status of the U.S. population, and discussing methods used to measure it. The chapter also explores the nurse's role in creating a culture of health by promoting actions through which good health and well-being can be achieved across geographic, demographic, and social sectors.

4.1 Defining Health

LEARNING OUTCOMES

By the end of this section, you should will be able to:

- 4.1.1 Discuss the different meanings of health.
- 4.1.2 Formulate a definition of health.
- 4.1.3 Explain the purpose of measuring health outcomes in a population.

What first comes to mind when you think about *health*? Many people would describe a healthy person as someone who eats nutritious food, exercises regularly, manages stress, spends time outdoors, and receives adequate rest.

The World Health Organization (WHO) defines **health** as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity” (n.d.-a). This holistic perspective considers how many factors are key components of an individual’s well-being. These factors, or *determinants of health*, include genetics, behavior, environment, physical influences, medical care, and social factors. Modifying one of these factors can have a positive or negative effect on a person’s health. For example, reducing sodium intake may have a positive effect, such as lowering high blood pressure. Conversely, smoking cigarettes may result in a negative consequence, such as increasing the risk of emphysema or lung cancer.

As [Social Determinants Affecting Health Outcomes](#) discusses in more depth, additional factors called **social determinants of health** (SDOH) affect an individual’s health and well-being. SDOH are “the conditions in the environments where people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks” (ODPHP, n.d.-j). They include economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context. For example, someone without a social support network or close family connections may feel disconnected from their community, leading to poor mental health.

SOCIAL DETERMINANTS OF HEALTH

[Access multimedia content \(<https://openstax.org/books/population-health/pages/4-1-defining-health>\)](https://openstax.org/books/population-health/pages/4-1-defining-health)

This brief video explores some of the practical effects of the social determinants of health. The scenario in the video depicts the ramifications of social differences from a child’s perspective.

Watch the video, and then respond to the following questions.

1. What characteristics of his community did A. J. identify that could affect his family’s health?
2. Consider your own community. What social factors are present that you think support the health of your community?
3. Again, considering your own community, what social determinants exist that negatively affect the community’s health?
4. What is something you can do to positively influence social conditions in your community?

What Does It Mean to Be Healthy?

How individuals view what it means to be healthy varies depending on how they define health. For example, those who perceive health as complete physical well-being may consider themselves unhealthy if they are diagnosed with a chronic illness like asthma. In contrast, someone with a holistic view of health may consider themselves healthy despite having a chronic condition if the illness does not significantly affect other aspects of their life. **Well-being**, or the subjective perception that life is going well, is important from a public health perspective, as it is an outcome that can be measured to determine the benefits of disease prevention and health promotion initiatives within a population. Well-being relates to overall life satisfaction and encompasses a range of factors, including physical, social, economic, emotional, and psychological, to name a few (CDC, 2018).

The term **health-related quality of life** (HRQL), sometimes abbreviated HRQOL, refers to the perceived physical and mental well-being of an individual or population. HRQL, although subjective, can be measured using a variety of surveys and scales (CDC, 2018). A healthy population can satisfy its needs and cope with a range of environments. The health of a population also often depends on the extent to which there is inequality in health outcomes within that population. Populations with the greatest lifespan variation also have the highest mean mortality rates (CDC, 2018; McCartney et al., 2019).

The attainment of health requires access to various resources and is also affected by the SDOH. The WHO and organizations such as the American Heart Association (AHA) and American Diabetes Association (ADA) provide health education designed to address the critical components of health, including access to health care, safe environment and transportation, healthy food and healthy habits, and mental health and social supports (ADA, n.d.; AHA, n.d.; WHO, 2019).

Factors necessary to attain health include the following:

- Access to health care: Factors such as health insurance and the availability and geographical location of health care facilities affect the health of individuals and communities (Office of Disease Prevention and Health Promotion [ODPHP], n.d.-a). Other factors include health literacy, or the ability to comprehend health information, and trust in the health care system, particularly if there are barriers such as socioeconomic or cultural disparities (CDC, 2023f; WHO, n.d.-c).
- Safe environment and transportation: The environment has a significant role in the health of individuals and communities. Physical safety; environmental safety, such as safe water; and the accessibility of employment, schools, and recreation all affect the health of community members (WHO, n.d.-c).
- Healthy food and healthy habits: The availability of healthy food, the ability to properly store food, and the development of healthy food habits all promote health. Other healthy habits, such as refraining from smoking or the harmful use of alcohol and engaging in physical activity, provide additional health benefits. Failure to engage in these healthy habits is a risk factor for many chronic diseases, such as cardiovascular disease and diabetes (ADA, n.d.; AHA, n.d.; WHO, 2019).
- Mental health and social supports: Mental health issues, such as depression, anxiety, and stress, have a negative effect on health. Individuals with chronic illnesses, such as diabetes, face additional stressors. The presence of social supports, such as family and friends, has positive health benefits. Individuals with chronic diseases, such as diabetes or cardiovascular disease, often benefit from support groups, which promote mental health (ADA, n.d.; AHA, n.d.; WHO, 2019).

WHAT DOES HEALTH MEAN TO YOU?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/4-1-defining-health>\)](https://openstax.org/books/population-health/pages/4-1-defining-health)

In this video from the World Health Organization (WHO), individuals from diverse cultures describe their personal definitions of health.

Watch the video, and then respond to the following questions.

1. What is your definition of health?
2. Which characteristics of health do the individuals interviewed mention consistently, if any?
3. How do their definitions compare to yours?

Health Outcomes

As discussed in [What Is Population Health?](#), population health looks beyond the individual client to consider the health of a group or larger community, as well as environmental, economic, social, behavioral, and other factors that influence health. One way to assess the health of a population is by measuring health outcomes. A **health outcome** is “a change in the health status of an individual, group or population that is attributable to a planned intervention or series of interventions, regardless of whether such an intervention was intended to change health status” (WHO, 2021a, p. 20). A health outcome related to an individual client would focus on the effectiveness of an intervention for that client. **Population health outcomes** consider broad topics related to a larger group or target population, such as **mortality rates**, life expectancy rates, quality of life, the prevalence of chronic conditions, or measures of

the frequency of death in a defined population during a specific time interval. Positive health outcomes include being alive with a sense of well-being and an ability to function well mentally, physically, and socially. Negative health outcomes include death, an inability to function, and a lack of well-being. Recall that numerous factors can affect both an individual's and a population's health.

THEORY IN ACTION

A Grassroots Population Health Initiative

[Access multimedia content \(<https://openstax.org/books/population-health/pages/4-1-defining-health>\)](https://openstax.org/books/population-health/pages/4-1-defining-health)

Efforts to improve a community's health can take all forms and can be driven by everyday citizens, not just by the community's leaders. Watch the video "Palm Beach County: Co-powering Solutions" to learn more about how a county in Florida "co-powered" its citizens to improve the county's "culture of health."

Watch the video, and then respond to the following questions.

1. How is the West Palm Beach community health initiative addressing mental health issues from a holistic perspective?
2. What factors did the initiative identify that negatively impact the community's health?
3. How did community members participate in identifying desired outcomes?

4.2 Performance Metrics

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 4.2.1 Explain the purpose of health indicators.
- 4.2.2 Identify approaches to measuring population health outcomes.
- 4.2.3 Differentiate between various types of health status indicators.
- 4.2.4 Discuss the nurse's role in managing population health.

Health indicators are health-related measures of data that are used to quantify and track an individual's health status. Measuring health indicators allows health care providers to assess improvement or decline in an individual's health over time. Just as health care providers follow individual health indicators, it is possible to measure health-related indicators for a population. Population health metrics are quantifiable group-level measures associated with health (Mathers et al., 2003; Pan American Health Organization, 2018; Roser et al., 2021). Health care professionals, researchers, and policymakers use these metrics to make decisions and plan population health initiatives. Positive indicators, such as life expectancy, correlate with better health. Negative indicators, such as infant mortality rate, are inversely correlated with health. See [Table 4.1](#) for examples of population health metrics.

Years of life lost (YLL)	A measure of premature mortality that considers both the frequency of death and the age at which it occurs, calculated by multiplying number of deaths by a standard life expectancy at the age at which death occurs; used to determine public health priorities (WHO, n.d.-f)
Years of healthy life lost due to disability (YLD)	The number of healthy years one might lose from their life due to disability or sickness (WHO, n.d.-e)
Disability-adjusted life years (DALYs)	The sum of the YLLs and YLDs attributable to a disease or health condition, with each DALY representing the loss of one year of full health (WHO, n.d.-b)
Quality-adjusted life years (QALYs)	The months or years of reasonable quality that an individual may gain following treatment; measures both length and quality of life of an individual (Health Analytics, 2022)

TABLE 4.1 Population Health Metrics

Measures of Population Health Outcomes

A population health measure is an indicator that reflects the quality of a group's overall health and well-being. Examples of measured topics include access to care, clinical outcomes, health behaviors, preventive care and screening, and utilization of health services. Life expectancy at birth, morbidity, mortality, and premature death are examples of population health outcome measures (Hernandez & Kim, 2022).

Life Expectancy at Birth

Life expectancy at birth refers to a population's overall mortality level, or the average age of death. It is an important measure for assessing population health, as it reflects mortality patterns across all age groups. Life expectancy at birth is calculated by identifying the number of deaths that occur in a population during an identified time frame and dividing it by the size of the population. This calculation is referred to as the population's mortality number. Disease- or cause-specific mortality rates are used to describe the contributions of specific diseases to a population's mortality, such as deaths related to heart disease or cancer (WHO, n.d.-d).

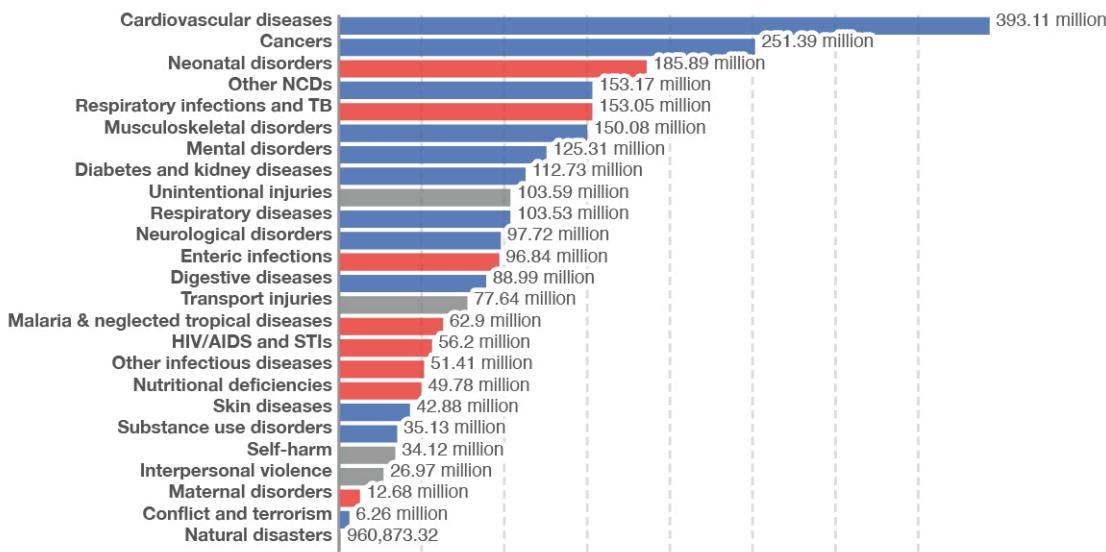

Morbidity and Mortality

Morbidity and mortality are two measures commonly used for epidemiological surveillance that describe the progression and severity of a given health event. They are useful tools for learning about risk factors for diseases and comparing health events between different populations. **Morbidity** is the state of being symptomatic or unhealthy due to a disease or condition and is usually represented or estimated using prevalence or **incidence**. **Prevalence** refers to the proportion of a population that has a disease or condition over a given time frame, whereas **incidence** refers to the number of new cases over a given time frame. **Mortality**, in contrast, refers to the number of deaths in each time frame. Years of life lost (YLL) measures premature deaths and has implications for public health, as risk factors can be addressed through health promotion initiatives (Hernandez & Kim, 2022; National Institute of Mental Health, n.d.; National Research Council & Institute of Medicine, 2015). See [Epidemiology for Informing Population/Community Health Decisions](#) for more information.

Combining mortality and morbidity rates gives a more comprehensive view of a population's health. While mortality rates are an accurate, straightforward indicator, they do not consider the effects of diseases people are living with. The measure of both indicators together is referred to as the **burden of disease** (Roser et al., 2021). The burden of disease is measured by disability-adjusted life years (DALYs). For example, cardiovascular disease is the disease with the greatest burden on the population. People with cardiovascular disease die prematurely from myocardial infarctions, congestive heart failure, and other cardiovascular conditions. Additionally, many people live for years with cardiovascular disease before they die, which is reflected in morbidity rates and the burden of disease. [Figure 4.2](#) shows the global burden of the most prevalent diseases in 2019, categorized by disease or injury.

Burden of disease by cause, World, 2019

Total disease burden, measured in Disability-Adjusted Life Years (DALYs) by sub-category of disease or injury. DALYs measure the total burden of disease – both from years of life lost due to premature death and years lived with a disability. One DALY equals one lost year of healthy life.

Data source: IHME, Global Burden of Disease (2019)

Note: Non-communicable diseases are shown in blue; communicable, maternal, neonatal and nutritional diseases in red; injuries in grey.

FIGURE 4.2 Before the COVID-19 pandemic in 2019, cardiovascular diseases were the number-one health burden in the world in terms of lost years of healthy life. (data source: Institute for Health Metrics and Evaluation, "Global Burden of Disease, 2019"; credit: "Burden of disease by cause, World, 2019" by Our World in Data, CC BY 4.0 International)

Summary Measures of Population Health

Summary measures of population health combine data from the basic metrics, such as mortality and nonfatal disease outcomes, to represent health in a single number (New Mexico Department of Health, 2021). Quality-adjusted life years (QALYs) is an example of a summary measure. An advantage of summary measures is that a single statistic is easier to communicate to the public and track over time than data from multiple basic metrics. Summary measures also provide information on the distribution and inequalities of health, which have implications for health programming.

Key Health Indicators Based on Subjective Data

In addition to the health indicators previously mentioned that rely on objective data, a population's health is also measured with key health indicators based on subjective data. Objective data, such as the ability to perform a physical task, are measurable. Subjective data require a person to self-rate their perception of their health.

Population health surveys, such as the Behavioral Risk Factor Surveillance System, the National Health and Nutrition Examination Survey, and the National Health Interview Survey, are examples of tools used to obtain key health indicators based on the population's perception.

Behavioral Risk Factor Surveillance System

The Behavioral Risk Factor Surveillance System (BRFSS) is a health-related telephone survey used throughout the United States to collect data on health risk behaviors, chronic health conditions, the use of preventive services, and other factors, such as health care access and use of health care services. The data are then used to identify groups at risk for developing chronic diseases, monitor changes in health risk factors and chronic disease rates, and develop local, state, and national health promotion strategies. This system has served as a valuable resource for health promotion at the state and local levels. Some of the topics covered in the 2022 telephone survey include exercise, adequacy of sleep, colorectal cancer screening, and alcohol consumption (National Center for Chronic Disease Prevention and Health Promotion [NCCDPHP], 2022b). A state-by-state listing of how the data were used to improve health outcomes is available on the website: [State-By-State Listing of How Data Are Used \(https://openstax.org/r/cdcbrfss\)](https://openstax.org/r/cdcbrfss).

The National Health and Nutrition Examination Survey

Ideally, an indicator would reflect both subjective and objective data. The National Health and Nutrition Examination Survey (NHANES) combines interviews and physical examinations to assess the nutritional health of U.S. adults and children. All participants are evaluated by a physician, are interviewed about their diet, and have body measurements taken. Most participants have lab work done and a dental screening performed. As participants age, more tests are incorporated. The survey identifies the prevalence of major diseases and the presence of risk factors for diseases. The data are then used in epidemiological studies and research that assist in developing public health policies, programs, and services. Past outcomes of this survey have included the pediatric growth charts that are used nationwide at well-child visits and the policy to eliminate lead from gasoline, food, and soft drink cans (National Center for Health Statistics, 2023c).

National Health Interview Survey

The National Health Interview Survey (NHIS) is the oldest ongoing health survey in the United States. Census workers conduct personal interviews in participants' homes to collect health data on a broad range of topics from a sample of noninstitutionalized, civilian Americans. They survey categorizes data by demographic and socioeconomic features. The data are used to track disease and disability status of Americans and to track progress toward the achievement of national health objectives (National Center for Health Statistics, 2023d).

Health-Related Quality of Life

As mentioned earlier in this chapter, HRQL refers to an individual's perceived physical and mental well-being. To track HRQL, the CDC uses a subset of questions called "Healthy Days measures" in both the BFSS and NHANES surveys. These questions ask the respondent to rate their overall health from excellent to poor, report how frequently in the past 30 days their physical or mental health was not good, and report how frequently during that same time frame poor physical or mental health kept them from doing their usual activities. The data are utilized for research, program planning, and tracking progress toward achieving Healthy People 2030 goals (CDC, 2021a).

The Nurse's Role in Managing Population Health

Nurses have traditionally practiced in a variety of community settings and are well positioned to identify patterns across populations, connect clients to community resources, and develop community interventions (Robert Wood Johnson Foundation, 2017). The role of the population health nurse is to support clients as they strive to attain positive health outcomes. The nurse must understand that although lifestyle choices play an essential role in health outcomes, those outcomes are also influenced, and often limited, by environmental and social factors. Nurses in all health care settings play an important role in helping clients understand what influences and drives health.

The passage of the Patient Protection and Affordable Care Act of 2010, or the Affordable Care Act (ACA) for short, shifted the emphasis of health care from episodic care of individuals to primary and preventive care of groups or populations. Population health management requires nurses to develop skills in understanding basic health metrics, measures of population health outcomes, and key health indicators. Understanding these concepts allows the nurse to comprehend the health status and risk levels of populations and the influence of the SDOH. Nurses must also evaluate the outcome of community-based interventions, which are based on data, and revise the interventions as indicated. The use of health metrics by nurses plays a key role in identifying health risk and developing interventions to improve the health of a population (Ariosto et al. 2018).

The Robert Wood Johnson Foundation released the *Catalyst for Change report* in 2017, urging nurses to expand their practice in communities, schools, businesses, homes, and hospitals to promote population health. Population health nurses take a holistic approach to managing a group's health, recognizing that health is influenced by many factors in a variety of settings. Nurses providing client care should monitor relevant metrics to identify needs and evaluate outcomes of interventions. Additionally, informatics nurse specialists can serve as resources to manage data to track health indicators and evaluate population outcomes.

Many nurses work with individual clients. However, community health nurses who work in public health or other community settings work to improve health outcomes of the population at large rather than those of individual clients. For example, when working with an individual client to manage their hypertension, the nurse will use that client's blood pressure measurements as data to monitor and evaluate the care provided to them. In contrast, population health measures the health of the entire group, not its individual members, using performance

measurements, or metrics. Examples of basic metrics used in population health include mortality and life expectancy rates. Population health nurses then use the data to provide evidence-based care to populations in need (NCCDPHP, 2023). Population health nurses working with the community will analyze data to identify modifiable risk factors—for hypertension, for example—and develop broad strategies to prevent or manage the disease. Examples of these interventions include educational offerings and blood pressure screenings.

Nurses can use health-related outcome measures to assess and monitor the health of the population. They can track metrics to identify and prioritize population health issues. For example, a public health nurse may utilize data from the BRFSS to track chronic diseases in an urban community. Based on this information, nurses can develop appropriate health promotion and disease prevention activities for the population that target desired health outcomes. The nurse may note an increase in diabetes prevalence in the community and use these data to formulate a plan to address this increase. Interventions could include assessing the availability of affordable and nutritious foods, access to primary care clinics, and availability of parks and green spaces conducive to exercise. Finally, nurses can monitor metrics to evaluate the effectiveness of policies and interventions.

4.3 Health in America

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 4.3.1 Identify public health priorities in the United States.
- 4.3.2 Discuss the leading causes of death in the United States.
- 4.3.3 Describe trends in mortality due to the most common infectious and chronic diseases across populations.
- 4.3.4 Discuss health trends in the United States.
- 4.3.5 Compare health outcomes in the United States with those of high-income or “peer” countries.
- 4.3.6 Describe the nurse’s role in addressing health inequities.

The United States has the highest health care spending compared to peer countries, such as Germany and France, but with worse health outcomes (Gunga et al., 2023; Hoyert, 2023). Infant and maternal mortality rates are higher than those of peer countries, and the life expectancy of Americans is lower. As first introduced in [What Is Population Health?](#), Healthy People is an initiative of the U.S. Department of Health and Human Services (HHS) to improve the health and well-being of all people in the United States. The Healthy People initiative began in 1980 with the launch of Healthy People 1990 (ODPHP, 2021b). Every 10 years, HHS releases updated national health objectives to shape health promotion and disease prevention efforts in the United States for the next decade. Healthy People 2030 is the most current version.

Healthy People 2030

The vision of **Healthy People 2030** is a society in which everyone can reach their full potential for health and well-being across their lifespan. Healthy People 2030’s mission is to support the nation’s efforts to improve the population’s health and well-being. Several foundational principles support Healthy People’s mission (ODPHP, 2021a). These principles use a holistic perspective of health and recognize the importance of equitable access to health care and health promotion. Working to achieve this vision is a shared responsibility among all individuals, groups, and organizations and is essential to creating a thriving, equitable society. Creating healthy physical, social, and economic environments and effective policy is essential for achieving the vision of Healthy People 2030. [Health Disparities](#) discusses the impact of health disparities and SDOH on care outcomes in more detail.

FIVE THINGS TO KNOW ABOUT HEALTHY PEOPLE 2030'S FRAMEWORK

[Access multimedia content \(<https://openstax.org/books/population-health/pages/4-3-health-in-america>\)](https://openstax.org/books/population-health/pages/4-3-health-in-america)

This video describes the Healthy People 2030 framework.

Watch the video, and then respond to the following questions.

1. Which of the focus areas is new to the Healthy People initiatives?
2. How did the definition of health literacy change?
3. Do you think this video is effective in explaining the fundamental concepts of Healthy People 2030 to the

lay public? Why or why not?

While the vision, mission, and foundational principles provide a framework essential for the utility of Healthy People 2030, the goals and objectives shape how the country's health experts work to identify priorities and implement targeted interventions. The overall goals of Healthy People include promoting health and well-being throughout the lifespan by creating supportive environments and public policy.

To measure the nation's progress toward the Healthy People 2030 vision, HHS has identified Overall Health and Well-Being Measures (OHMs). The OHMs are used to assess the Healthy People 2030 vision over its 10-year span to determine the overall health and well-being of the U.S. population and see where improvements have occurred. Because they are broad goals, OHMs do not have targets and are not classified as objectives (ODPHP, n.d.-e). The OHMs are subdivided into three tiers, as shown in [Table 4.2](#).

Tiers	OHMs
Well-being	OHM-01: Overall well-being (expressed as overall life satisfaction, reflecting the cumulative contributions of health and non-health factors)
Healthy life expectancy	OHM-02: Life expectancy at birth—free of activity limitation OHM-03: Life expectancy at birth—free of disability OHM-04: Life expectancy at birth— in good or better health
Summary mortality and health	OHM-05: Life expectancy at birth OHM-06: Free of activity limitation OHM-07: Free of disability OHM-08: Respondent-assessed health status—in good or better health

TABLE 4.2 Healthy People 2030 Overall Health and Well-Being Measures (See ODPHP, n.d.-e.)

The next layer of the Healthy People framework includes the core, developmental, and research objectives. Within the core objectives, Healthy People 2030 identifies high-priority health issues and challenges, which are referred to as **leading health indicators** (LHIs). LHIs are objectives that cover the lifespan and allow for the assessment and promotion of health at the community, state, and national levels (ODPHP, n.d.-d). LHIs address high-priority issues that have a significant effect on health outcomes. The indicators must address the SDOH; **health disparities**, which are preventable differences of health among populations; and **health equity**, or the expectation that everyone has a fair opportunity to attain their highest level of health. LHIs are modifiable, meaning they can be improved by implementing evidence-based interventions and strategies. The LHIs were developed to focus resources on the major causes of death and disease, aiming to improve health (ODPHP, n.d.-c).

An example of an intervention for the LHI of children and adolescents with obesity was a study conducted by a school nurse to promote healthy choices. The relevant Healthy People 2030 objective is to “reduce the proportion of children and adolescents with obesity” (ODPHP, n.d.-h), and students in this study earned points toward a special healthy class snack for each healthy choice they made. The study resulted in a 25 percent decrease in the consumption of chocolate milk, demonstrating the positive effect that a health promotion intervention can have on an LHI (Lovell, 2018). Each LHI represents an opportunity to develop health promotion activities that address the modifiable risk factors leading to death and disease. [Figure 4.3](#) illustrates the relationship between the OHMs, objectives, and LHIs.

Healthy People 2030 Objectives and Measures

FIGURE 4.3 Healthy People 2030 includes overall outcome measures as well as more specific objectives to direct health promotion efforts. (credit: "Healthy People 2030 Objectives and Measures" by the Office of Disease Prevention and Health Promotion/U.S. Department of Health and Human Services, Public Domain)

Leading Causes of Death in the United States

According to the National Center for Health Statistics (2023b), the following were the 10 leading causes of death in the United States in 2021:

1. Heart disease
2. Cancer
3. COVID-19
4. Accidents (unintentional injuries)
5. Stroke (cerebrovascular diseases)
6. Chronic lower respiratory diseases
7. Alzheimer's disease
8. Diabetes
9. Chronic liver disease and cirrhosis
10. Nephritis, nephrotic syndrome, and nephrosis

Tracking shifts in mortality trends serves as a guide for developing public health policies and interventions. In 2020, for example, the prevalence of COVID-19 and COVID-19-related deaths led the United States to declare a national state of emergency. State governments implemented policies such as travel restrictions, school closures, physical distancing, and mask wearing based on COVID-19 case rates. Although initially delayed, testing for COVID-19 infection was implemented to obtain surveillance data that was then used to prevent transmission, ultimately leading to decreased mortality rates (Unruh et al., 2022; CDC, 2023a).

Population health nurses must be familiar with disease trends. The following section briefly reviews the leading causes of death in the United States.

Heart Disease

Heart disease has been the leading cause of death globally for more than 20 years and is the most common cause of death in the United States for both men and women overall, as well as for most racial and ethnic groups (CDC,

2023d; World Heart Federation, 2023). The key risk factors for developing this condition include high blood pressure and high blood cholesterol. Several modifiable risk factors, such as smoking, obesity, and physical inactivity, contribute to the development of heart disease, and public health efforts are in place to create awareness (CDC, 2023d). For example, the American Heart Association (AHA) sponsors the [Go Red for Women Health Movement](https://openstax.org/r/goredforwomen) (<https://openstax.org/r/goredforwomen>) to create awareness about heart disease in women.

Cancer

Although deaths from cancer have decreased over the past 30 years, it remains the second leading cause of death in the United States. Lung cancer is the most prevalent cause of cancer death, followed by colorectal, pancreatic, breast, and prostate cancer. Public health campaigns to increase awareness of cancer risk factors, such as smoking, as well as advances in screening and treatment, have contributed to the decrease in cancer deaths (American Cancer Society, 2022; CDC, 2022b). The CDC supports initiatives such as the National Breast and Cervical Cancer Early Detection Program ([NBCCEDP](https://openstax.org/r/cdccancer) (<https://openstax.org/r/cdccancer>)) to reduce cancer deaths (CDC, 2022b).

Accidents

Accidents or unintentional injuries were the third leading cause of death in the United States in 2022 (Ahmad et al., 2023). The CDC (2022a) identifies unintentional injuries such as unintentional poisoning (including opioid and other drug overdoses), drowning, motor vehicle accidents, and falls as the leading cause of death for Americans aged 1 to 44 years old. Interventions to prevent death from these types of injuries are included in the Healthy People 2030 objectives. For example, as drug overdoses are the leading cause of unintentional deaths, Healthy People 2030 supports interventions such as the distribution of naloxone and providing medication for addiction treatment, and HHS has a prevention strategy for preventing overdoses (ODPHP, n.d.-c;).

COVID-19

As indicated previously, after the start of the pandemic, COVID-19 quickly became a leading cause of death, with the weekly death toll peaking in the week of January 9, 2021, at more than 25,000 deaths per week (CDC, 2023a). However, COVID-19-related deaths have since dropped, and according to the CDC's provisional mortality data for 2022, it was the fourth leading cause of death that year (Ahmad et al., 2023). It is unclear at this time if COVID-19 will remain a leading cause of death.

The COVID-19 pandemic has strained global health systems and the health care workforce. Even before the pandemic, there was a long-standing health care worker shortage, and the WHO currently predicts a global shortfall of 18 million health care workers by the year 2030, although more recent data indicate these numbers may be improving (WHO, 2022d). The WHO groups its member states into six regions for purposes of data analysis and reporting (GreenFacts, 2023). The health care workforce shortage is of high concern in the African region, which consists of 46 countries, because it bears almost one-quarter (24 percent) of the world's disease burden but has only 3 percent of the world's health care workers (WHO, 2022d).

Stroke

Stroke is the fifth leading cause of death in the United States. Deaths from stroke have increased from 2018 and are more likely to occur among low-income populations, certain racial and ethnic groups, and populations in certain parts of the country. The risk of stroke can be decreased by controlling high blood pressure and treating high cholesterol levels. Teaching people to recognize symptoms is key to helping more people get the treatment they need in a stroke emergency (ODPHP, n.d.-g).

Chronic Lower Respiratory Disease

Emphysema, chronic bronchitis, and nonreversible asthma belong to a group of illnesses known as chronic obstructive pulmonary disease, or COPD. The symptoms of COPD make it hard to breathe and can cause death. COPD is a major cause of disability and one of the leading causes of death in the United States. Unfortunately, many people who have COPD may not know it. Healthy People 2030 has a goal to reduce emergency department visits for COPD by reducing smoking and exposure to air pollution, teaching people with COPD how to manage it, and promoting early detection (ODPHP, n.d.-f).

Alzheimer's Disease

Alzheimer's disease is a type of dementia characterized by cognitive decline. Growing research suggests ways to help prevent or delay dementia instead of merely treating it and reducing its impact. Although no cure is presently

available to eliminate Alzheimer's disease, early recognition and early intervention may slow its deteriorating progress (ODPHP, n.d.-d).

Diabetes

Adults who are diagnosed with diabetes are at an increased risk of early death. Complications such as heart disease and kidney disease are among the leading causes of death in people with diabetes. Improving diabetes treatments may reduce the risk for these complications and lower the death rate for people with diabetes (ODPHP, n.d.-b).

Chronic Liver Disease, Cirrhosis, and Nonalcoholic Fatty Liver Disease

In the United States, chronic liver disease and cirrhosis are among the leading causes of death. Notably, death rates have been consistently higher for Black Americans. Most cirrhosis deaths are due to alcohol use. Other risk factors include type 2 diabetes, injecting drugs using shared needles, and exposure to others' blood and body fluids (American Liver Foundation, 2022). Effective policies to reduce cirrhosis deaths include taxing and regulating alcohol sales and restricting alcohol advertising. According to the WHO (2023g), alcohol taxation and price regulation are among the most effective strategies to decrease alcohol-related harm.

Nonalcoholic fatty liver disease (NAFLD) develops when excess fat builds up in the liver for reasons unrelated to alcohol use. This is one of the most common causes of liver disease and is associated with obesity and type 2 diabetes. NAFLD increases a person's risk of cardiovascular disease, type 2 diabetes, and metabolic syndrome (National Institute of Diabetes and Digestive and Kidney Diseases [NIDDK], n.d.).

Nephritis, Nephrotic Syndrome, and Nephrosis

Nephritis and nephrotic syndrome/nephrosis are forms of kidney disease and a leading cause of death in the United States. Nephritis is an inflammatory condition, frequently resulting from infection, that can lead to renal failure if untreated. Nephrosis or nephrotic syndrome is a group of symptoms that reflect poor renal function caused by renal diseases or other causes, such as diabetes or hepatitis. The symptoms include proteinuria, hypoalbuminemia, peripheral edema, and hyperlipidemia (NIDDK, n.d.). Chronic kidney disease affects more than one in seven adults, and many do not realize they have it (NIDDK, 2023). Additionally, these conditions disproportionately affect low-income and racial and ethnic minority groups (ODPHP, n.d.-a; Norris, 2021).

Trends in Mortality

Over the past 100 years in the United States, life expectancy has increased and rates of death have decreased.

[Figure 4.4](#) depicts the death and life expectancy rates for the United States from 1900 to 2018 (National Center for Health Statistics, 2022).

Age-adjusted Death Rates and Life Expectancy at Birth, United States, 1900 to 2018

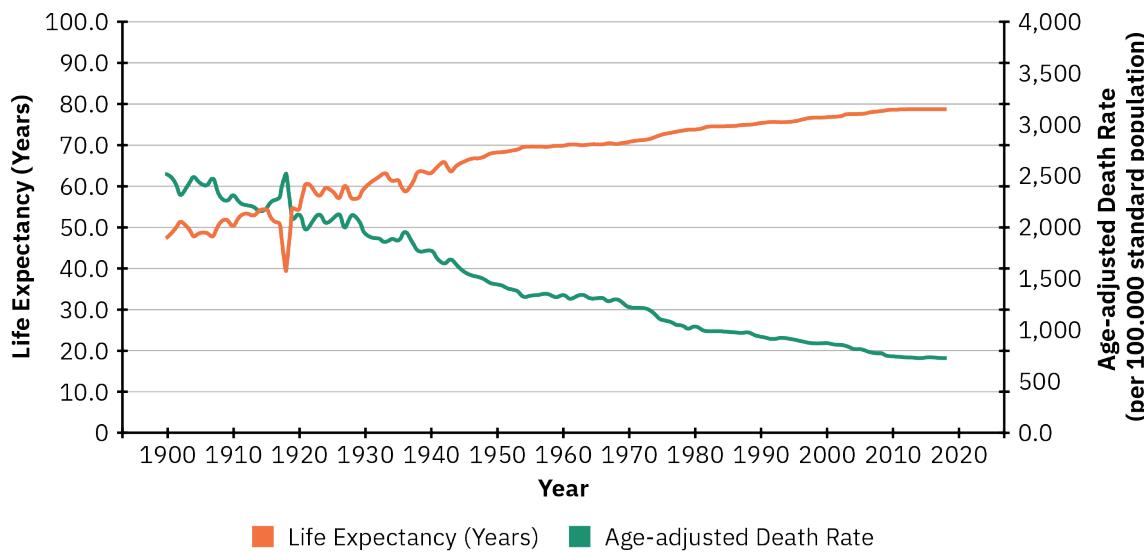

FIGURE 4.4 After decades of increases, life expectancy in the United States has slowly begun to decline. (data source: "Age-adjusted Death Rates and Life Expectancy at Birth (Both Sexes, All Races): United States, 1900 to 2018" by Centers for Disease Control and Prevention, Public Domain; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

An unprecedented decline in mortality occurred during the 20th century in the United States, and life expectancy rose by more than 30 years during this time frame. Infectious diseases were the leading cause of mortality in the early 1900s. Urbanization and the resulting increased population density provided a prime opportunity for diseases such as tuberculosis and influenza to spread. Improvements in sanitation and nutrition, coupled with the development of antibiotics, led to a sharp decline in deaths from infectious diseases. As the death rate from infectious diseases decreased, chronic illnesses emerged as the primary cause of mortality. Smoking, for example, was identified as a leading cause of cardiovascular disease and cancer. Public health campaigns successfully developed awareness of smoking risks, resulting in decreased chronic diseases attributed to tobacco use (The Wharton School, 2016).

Following decades of increases, life expectancy in the United States is now falling (National Center for Health Statistics, 2022). One factor alone is not responsible for this drop, and there are also disparities in mortality rates among population groups within the United States. The next section will explore trends in mortality as a starting point to develop an understanding of this concerning change (Shmerling, 2022).

Mortality Trends in Infectious Disease

Infectious disease remains a public health threat in the United States despite its decline as a leading cause of mortality. COVID-19, as previously discussed, is still a leading cause of death in the United States. Americans of all ages are at risk for mortality from other infectious diseases, such as bacterial sepsis in newborns or influenza and pneumonia for people from 1 year of age through late adulthood. Vaccines, such as those for COVID-19 and influenza, significantly reduce the risk of these infectious diseases and their complications (CDC, 2021b).

Mortality Trends in Chronic Disease

Chronic disease is a condition that is present for more than 1 year and requires ongoing medical intervention and/or limits activities of daily living. According to the National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP, 2022c), 6 out of 10 Americans have one chronic disease, and 4 in 10 have two or more. The major chronic diseases in the United States include heart disease and stroke, diabetes, and cancer. These diseases are the leading causes of death and disability in the United States and share the same risk factors, which include:

- tobacco use,
- exposure to secondhand smoke,
- poor nutrition,
- physical inactivity, and
- excessive alcohol use.

Chronic diseases account for most health care costs in the United States, and interventions to prevent them have significant economic and health benefits for Americans (NCCDPHP, 2022a). Because it is estimated that by 2050, most Americans aged 50 years and above across all races will have one or more chronic conditions, it is imperative that health promotion efforts address this concerning trend (Ansah & Chiu, 2022).

Mortality Trends in Suicide and Drug Overdose

Suicide is a major public health concern in the United States. As defined by the National Institutes of Health, suicide is death caused by self-directed injurious behavior with intent to die as a result of the behavior. Suicide rates increased by 37 percent between the years 2000 and 2018 and then decreased by 5 percent between 2018 and 2020. Unfortunately, rates nearly returned to their peak in 2021 (National Institute of Mental Health, 2023). Suicide is a leading cause of death for Americans aged 10 to 34. High suicide rates correlate to certain demographic factors, such as Native American ethnicity, and certain occupations, such as military service. Research suggests that increased suicide rates correlate to increases in mood and affective disorders and are associated with alcohol and drug use (Martinez-Ales et al., 2020).

Drug overdoses can be intentional or unintentional. The United States is currently experiencing an opioid overdose epidemic. There were more than six times the number of fatal drug overdoses in 2021 compared to 1999. The epidemic involves three waves or types of deaths. The initial wave started with prescription opioids in the 1990s, followed by increases in heroin-related deaths in 2010, and the third wave began in 2013 with synthetic opioids such as illegally manufactured fentanyl (CDC, 2023g). For more information on drug overdoses, refer to [Caring for Populations and Communities in Crisis](#).

Trends in Maternal-Newborn Mortality

In the United States, maternal mortality is measured in three different ways. *Pregnancy-associated* deaths are those that occur during pregnancy or within a year after the end of pregnancy, regardless of the cause of death.

Pregnancy-related deaths occur either during pregnancy or within one year after the end of pregnancy from a pregnancy-related complication; days 43 to 365 postpartum are considered “late” maternal deaths. Finally, *maternal mortality* refers to deaths that occur while pregnant or within 42 days after the end of pregnancy from any cause related to or aggravated by the pregnancy or its management, not including accidental or incidental causes. Nurses should understand these distinctions because many pregnancy-related deaths in the United States occur during the postpartum period (Tikkanen et al., 2020).

The maternal mortality rate in the United States exceeds that of other high-income countries and is increasing (Douthard et al., 2021). This trend is concerning, as the mortality rate of peer countries is decreasing, and more than 8 out of 10 maternal deaths are preventable. The maternal mortality rate is exceptionally high for Black Americans (Trost et al., 2022). Adverse maternal outcomes are often related to a combination of factors, such as an increased prevalence of chronic conditions, barriers to health care, or pregnant clients’ distrust of the health care system. Pregnant clients also experience variations in the quality of care they receive throughout the pregnancy, which is related to geographical location and socioeconomic status (Collier & Molina, 2019).

Infant mortality refers to an infant’s death before their first birthday, and the rate in the United States also exceeds that of peer countries (Petrullo, 2023). Infants born to Black people in the United States are at higher risk for mortality than those born to White people (Office of Minority Health, 2022). A primary cause of infant mortality is maternal pregnancy complications. Social and economic inequities drive maternal and infant mortality disparities in the United States. Initiatives at the federal, state, and community levels are striving to address the maternal and infant health crisis in America. Preventing pregnancy complications and maternal death is also a Healthy People 2030 goal (Hill et al., 2022).

Health Care Disparities

Various factors are responsible for the health disparities, or preventable differences in attaining health, among population groups in the United States. Disparities exist along many dimensions, including race or ethnicity, sexual orientation, age, socioeconomic status, and geographic location. Health care disparities can originate from health inequities, which are avoidable differences in the health of groups and communities (National Academies of Sciences, Engineering, and Medicine, 2017; Ndugga & Artiga, 2023). Barriers such as a lack of insurance or transportation and cultural differences between clients and providers affect health care quality. All Americans deserve an opportunity to attain their highest health level, which will only occur if disparities are addressed and health equity is achieved (CDC, 2022e). [Health Disparities](#) covers this topic in greater detail.

THE ROOTS OF HEALTH INEQUITIES

Disparities in Cause-Specific Mortality

In a recent review of U.S. deaths from 2000 to 2019, National Center for Health Statistics researchers determined that non-Hispanic American Indians or Alaska Natives (AIAN) and non-Hispanic Black Americans experienced higher mortality rates than White, Asian, and Latina/Latino Americans. These findings highlight the pervasive nature of health disparities that urgently need to be addressed.

(See GBD U.S. Health Disparities Collaborators, 2023.)

Health Trends in the United States

There are several notable positive health trends in the United States. Deaths attributed to heart disease, despite it being the leading cause of death, are on the decline. The age-adjusted heart disease death rate decreased from 182.8 per 100,000 in 2009 to 161.5 per 100,000 in 2019 (CDC, 2023d). Other trends include the following (National Center for Health Statistics, 2023a):

- The percentage of children with asthma declined from 9.6 percent in 2009 to 7.0 percent in 2019.
- Cigarette smoking among adults declined from 20.6 percent in 2009 to 14.2 percent in 2019.

- In 2019, 12.0 percent of Americans under age 65 were uninsured, which is down from 17.5 percent in 2009.
- In 2019, 8.5 percent of people delayed or did not receive medical care due to cost in the past 12 months, compared with 11.4 percent in 2009.

Healthy People 2030 data suggest that several goals and objectives for specific leading health indicators have improved or are improving. For example, more adults use information technology to track health care data or communicate with providers. The number of toxic pollutants released into the environment has improved, and the overall cancer death rate is improving (ODPHP, n.d.-d).

Not all trends are positive. For example, rural Americans are at greater risk for poor health outcomes and face more disparities than their urban counterparts. In 2019, the death rate for people living in rural areas was 20 percent higher than for those living in urban areas (Curtin & Spencer, 2021). A higher incidence of poverty, less access to health care, and longer distances to health care services negatively affect this demographic's health status. Modifiable risk factors, such as smoking, limited leisure-time physical activity, and lack of seat belt use, also contribute to poor health outcomes for rural Americans. The rates of the 10 leading causes of death in the United States were also higher in 2019 in rural areas than in urban areas (Curtin & Spencer, 2021). Rural health promotion initiatives are indicated to improve the health of those living in rural areas (CDC, 2023c; Curtin & Spencer, 2021). In addition, suicide rates have increased in almost every state over the last two decades (ODPHP, n.d.-i).

U.S. HEALTH MAP

Visit the Institute for Health Metrics and Evaluation's [U.S. Health Map](https://openstax.org/r/healthdataorg) (<https://openstax.org/r/healthdataorg>), an interactive map showing life expectancy and cause-specific mortality by race and ethnicity. Select a community of interest to view life expectancy or mortality rates at the county level, and then respond to the following questions.

1. How does the county you selected compare to surrounding counties?
2. Are the statistics consistent with what you expected? Why or why not?
3. How might a public health or community health nurse use this tool?

Comparison Between United States and Other High-Income Countries

The United States spends more on health care and medical technologies than other high-income countries and outperforms them on preventive measures, such as flu vaccines and cancer screenings. However, the United States has poor health outcomes and the lowest life expectancy compared to peer countries. Contributing factors include a low supply of physicians, a high incidence of chronic diseases, and obesity rates that are twice the average of peer countries (Tikkanen & Abrams, 2020). The data obtained from comparing the performance of the U.S. health care system against peer countries can be used to address areas in need of improvement. Improving access to health care, including availability and affordability, is a key factor in improving health outcomes (Tikkanen & Abrams, 2020). To find out more about how the United States compares to other countries, visit this [Health System Tracker](https://openstax.org/r/healthsystemtracker) (<https://openstax.org/r/healthsystemtracker>) from the Peterson Center on Healthcare and KFF.

THE REAL REASON AMERICAN HEALTH CARE IS SO EXPENSIVE

[Access multimedia content](https://openstax.org/books/population-health/pages/4-3-health-in-america) (<https://openstax.org/books/population-health/pages/4-3-health-in-america>)

This video examines why the United States spends so much money on health care but ranks lower in overall efficiency than other, similar countries.

Watch the video, and then respond to the following questions.

1. Name three factors that drive health care costs in the United States.
2. Why is health care less expensive in other countries?
3. Why does the patient-as-a-consumer model not work in health care, according to the video? Do you agree or disagree?

The Nurse's Role in Addressing Health Inequities

Nurses have a professional and moral responsibility to address the inequities that are embedded in the U.S. health care system. Access to health care is a key component of equitable care, and nurses are uniquely qualified to assist Americans in navigating the health care system. Nurses in all health care settings play an essential role in identifying and addressing barriers to care by providing person-centered care. This model addresses the physical, mental, and social needs of clients, families, and caregivers. Nurses in population health can work as case managers and connect their clients with appropriate resources to meet their health-related needs. Nurses can match community resources with learning opportunities, reduce health disparities, and assist in processing the outcomes of community-based interventions (Arisoto et al., 2018).

In addition to working directly with groups of clients, nurses must advocate for policies that improve access to care for all Americans (Oruche & Zapolski, 2020). There are several ways nurses can become more involved in the policymaking process, including:

- joining a professional nurses association or other politically active health care organization which can provide an opportunity to learn more about and participate in the policymaking process;
- building relationships with elected officials to raise their awareness of health-related issues; and
- educating clients on how they can become politically active and affect positive health-related policy changes.

The nurse's role in population health extends to many areas of health. The leading health indicators identified by Healthy People 2030 serve as a good starting point for addressing priority issues. For example, a nurse can work with Head Start programs, school systems, and day care centers to bring mobile dental hygiene care to students. A school nurse can advocate for and implement changes regarding the content of school vending machines and healthier menus for school breakfast and lunch options. The nurse may address drug overdose deaths by educating the community on the use of Narcan or expanding access to methadone clinics. The nurse can work with state and local governments on plans to address pollution issues by planting more trees or address traffic issues to minimize exhaust fumes associated with car idling. See [Advocating for Population Health](#) for more information on how nurses may participate in advocacy efforts.

4.4 World Health Statistics

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 4.4.1 Discuss the role of sustainable development goals (SDGs) in ensuring health equity.
- 4.4.2 Recognize the Global Burden of Disease (GBD) study as a tool to quantify global health priorities.
- 4.4.3 Examine global disease estimates to develop an understanding of global health challenges.
- 4.4.4 Recognize how health in the United States intersects with global health.
- 4.4.5 Describe the nurse's role in global health.

World health statistics are important to health care on a global basis. People continue to live longer and live more years in good health. The global life expectancy at birth increased from 66.8 years in 2000 to 73.3 years in 2019, and healthy life expectancy (HALE) increased from 58.3 years to 63.7 years (WHO, 2022b).

Despite these increases in life expectancy, health inequalities continue to take a toll on the lives and health of populations in areas that lack adequate resources. Both life expectancy and HALE were at least 10 years lower in lower-income countries than in higher-income countries. However, the total gains in life expectancy and HALE greatly impact mortality and morbidity. In the past 30 years, improvements have been made in global maternal and child health, with the global maternal mortality ratio and the under-5 mortality rate falling by nearly 40 percent and 60 percent, respectively, since 2000 (WHO, 2022b). From 2000 to 2020, the global maternal mortality ratio (MMR), or the number of maternal deaths per 100,000 live births, fell by about 34 percent worldwide. Almost 95 percent of all maternal deaths occurred in low- and lower-middle-income countries in 2020 (WHO, 2023a).

Sustainable Development Goals

United Nations (UN) member countries developed **sustainable development goals** (SDGs) in 2015 to create a world that is more fair, just, and equitable. SDGs are a 15-year plan with 17 interlinking goals that are a call to action to address global challenges such as poverty, inequality, climate change, peace, and justice ([Table 4.3](#)). The goals are

aimed at all countries, including those that are developed and those that are developing. SDGs are organized into five categories: people, planet, prosperity, peace, and partnerships. SDGs related to people include ending poverty and hunger and ensuring everyone can fulfill their potential in a healthy environment. Goals related to the planet address climate change and managing natural resources. Prosperity goals, such as those related to education, economic growth, and gender equality, are to ensure that all human beings can enjoy fulfilling lives. Peace SDGs foster both peace and inclusive societies. Successful implementation of the 17 SDGs requires partnerships and global solidarity. The goals are transformational and, if implemented, will lead to an equitable world that supports the human rights of all people (United Nations, n.d.).

Sustainable Development Goals		Examples of Targets
1	End poverty in all its forms everywhere.	<ul style="list-style-type: none"> By 2030, eradicate extreme poverty for all people everywhere, currently measured as people living on less than \$1.25 a day. By 2030, reduce at least by half the proportion of people of all ages living in poverty in all its dimensions according to national definitions.
2	End hunger, achieve food security and improved nutrition, and promote sustainable agriculture.	<ul style="list-style-type: none"> By 2030, end hunger and ensure access by all people, in particular the poor and people in vulnerable situations, including infants, to safe, nutritious, and sufficient food all year round. By 2030, double the agricultural productivity and incomes of small-scale food producers, in particular women, Indigenous peoples, family farmers, pastoralists, and fishers, including through secure and equal access to land, other productive resources and inputs, knowledge, financial services, markets, and opportunities for value addition and non-farm employment.
3	Ensure healthy lives and promote well-being for all at all ages.	<ul style="list-style-type: none"> By 2030, reduce the global maternal mortality ratio to less than 70 per 100,000 live births. By 2030, end preventable deaths of newborns and children under 5 years of age, with all countries aiming to reduce neonatal mortality to at least as low as 12 per 1,000 live births and under-5 mortality to at least as low as 25 per 1,000 live births.
4	Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all.	<ul style="list-style-type: none"> By 2030, ensure that all youth complete free, equitable, and quality primary and secondary education, leading to relevant and effective learning outcomes. By 2030, ensure that all youth and a substantial proportion of adults of all genders achieve literacy and numeracy.
5	Achieve gender equality and empower all women and girls.	<ul style="list-style-type: none"> End all forms of discrimination against all women and girls everywhere. Eliminate all forms of violence against all women and girls in the public and private spheres, including trafficking and sexual and other types of exploitation.
6	Ensure availability and sustainable management of water and sanitation for all.	<ul style="list-style-type: none"> By 2030, achieve universal and equitable access to safe and affordable drinking water for all. By 2030, achieve access to adequate and equitable sanitation and hygiene for all and end open defecation, paying special attention to the needs of women and girls and those in vulnerable situations.

TABLE 4.3 The 17 UN Sustainable Development Goals (See United Nations, n.d.)

Sustainable Development Goals		Examples of Targets
7	Ensure access to affordable, reliable, sustainable, and modern energy for all.	<ul style="list-style-type: none"> • By 2030, ensure universal access to affordable, reliable, and modern energy services. • By 2030, double the global rate of improvement in energy efficiency.
8	Promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all.	<ul style="list-style-type: none"> • Sustain per capita economic growth in accordance with national circumstances and, in particular, at least 7% gross domestic product growth per annum in the least developed countries. • Achieve higher levels of economic productivity through diversification, technological upgrading, and innovation, including through a focus on high-value-added and labor-intensive sectors.
9	Build resilient infrastructure, promote inclusive and sustainable industrialization, and foster innovation.	<ul style="list-style-type: none"> • Develop quality, reliable, sustainable, and resilient infrastructure, including regional and transborder infrastructure, to support economic development and human well-being, with a focus on affordable and equitable access for all. • Promote inclusive and sustainable industrialization and, by 2030, significantly raise industry's share of employment and gross domestic product, in line with national circumstances, and double its share in least developed countries.
10	Reduce inequality within and among countries.	<ul style="list-style-type: none"> • By 2030, progressively achieve and sustain income growth of the bottom 40% of the population at a rate higher than the national average. • By 2030, empower and promote the social, economic, and political inclusion of all, irrespective of age, sex, disability, race, ethnicity, origin, religion, or economic or other status.
11	Make cities and human settlements inclusive, safe, resilient, and sustainable.	<ul style="list-style-type: none"> • By 2030, ensure access for all to adequate, safe, and affordable housing and basic services and upgrade slums. • By 2030, provide access to safe, affordable, accessible, and sustainable transport systems for all, improving road safety, notably by expanding public transport, with special attention to the needs of those in vulnerable situations, women, children, persons with disabilities, and older persons.
12	Ensure sustainable consumption and production patterns.	<ul style="list-style-type: none"> • Implement the 10-Year Framework of Programmes on Sustainable Consumption and Production Patterns, all countries taking action, with developed countries taking the lead, taking into account the development and capabilities of developing countries. • By 2030, substantially reduce waste generation through prevention, reduction, recycling, and reuse.
13	Take urgent action to combat climate change and its impacts.	<ul style="list-style-type: none"> • Strengthen resilience and adaptive capacity to climate-related hazards and natural disasters in all countries. • Integrate climate change measures into national policies, strategies, and planning.

TABLE 4.3 The 17 UN Sustainable Development Goals (See United Nations, n.d.)

Sustainable Development Goals	Examples of Targets
14 Conserve and sustainably use the oceans, seas, and marine resources for sustainable development.	<ul style="list-style-type: none"> By 2025, prevent and significantly reduce marine pollution of all kinds, in particular from land-based activities, including marine debris and nutrient pollution. Minimize and address the impacts of ocean acidification, including through enhanced scientific cooperation at all levels.
15 Protect, restore, and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss.	<ul style="list-style-type: none"> By 2030, combat desertification, restore degraded land and soil, including land affected by desertification, drought, and floods, and strive to achieve a land-degradation-neutral world. Take urgent and significant action to reduce the degradation of natural habitats, halt the loss of biodiversity, and, by 2020, protect and prevent the extinction of threatened species.
16 Promote peaceful and inclusive societies for sustainable development, provide access to justice for all, and build effective, accountable, and inclusive institutions at all levels.	<ul style="list-style-type: none"> Significantly reduce all forms of violence and related death rates everywhere. End abuse, exploitation, trafficking, and all forms of violence against and torture of children. By 2030, significantly reduce illicit financial and arms flows, strengthen the recovery and return of stolen assets, and combat all forms of organized crime.
17 Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development.	<ul style="list-style-type: none"> Strengthen domestic resource mobilization, including through international support to developing countries, to improve domestic capacity for tax and other revenue collection. Mobilize additional financial resources for developing countries from multiple sources.

TABLE 4.3 The 17 UN Sustainable Development Goals (See United Nations, n.d.)

The UN reports on progress toward realizing the SDGs annually. The 2022 report reveals that the goals are in jeopardy due to factors such as the COVID-19 pandemic, the war in Ukraine, and the climate crisis. The pandemic disrupted essential health services and pushed more people into extreme poverty, largely eradicating progress that had been made in this area. The war in Ukraine has heightened the risk of a global food crisis. Supply chains and global trade have been disrupted, and food, fuel, and fertilizer prices have increased dramatically. Effects of climate change, including floods, fires, and droughts, are affecting ecosystems worldwide. Based on the 2022 report, the UN has identified addressing inflation, ending armed conflict, addressing the root causes of increasing inequality, and mitigating climate change as priorities if the SDGs are to be realized (United Nations, n.d.).

Global Health Priorities

In today's interconnected society, a threat in one area of the globe is a threat everywhere. The **Global Burden of Disease** (GBD) study is a resource that studies the changing health care needs and challenges worldwide in the 21st century. This study is conducted by the Institute for Health Metrics and Evaluation (IHME) and is used worldwide to help improve the lives of people. Among the key findings of the 2019 report are that the health of the world's population is steadily improving, and global life expectancy has increased. Urgent action is needed, however, to address concerns such as the global crisis related to chronic diseases and risk factors, trends in maternal and child health, assessing the impact of the COVID-19 pandemic, and the relationship between climate change and health (IHME, 2020). This section reviews the top global health priorities.

GLOBAL BURDEN OF DISEASE

Visit the Institute for Health Metrics and Evaluation [Global Burden of Disease](https://openstax.org/r/healthdataresearch) (<https://openstax.org/r/healthdataresearch>) (GBD) website to view global health indicator data. Select a health condition/risk factor or

location of interest, find relevant data to learn more about the health status of a particular population, and then respond to the following questions.

1. Are the data consistent with what you expected to find on your topic?
2. How can the data be used to measure a population's health decline?

Cardiovascular Diseases

Cardiovascular diseases (CVDs) are a leading cause of death globally, representing 32 percent of all deaths (Coronado et al., 2022). Most CVDs are associated with risk factors such as tobacco use, unhealthy diet and obesity, physical inactivity, and harmful alcohol use. The burden of CVDs can be reduced by addressing these modifiable risk factors and through CVD management interventions, such as controlling hypertension and managing acute events such as heart attacks promptly (WHO, 2021b). Three-quarters of deaths from CVDs occur in low- and middle-income countries in which access to primary care is limited, resulting in late diagnosis of CVD. Improvements in CVD statistics will only occur when health care systems are strengthened globally (WHO, 2021b).

Diabetes

Diabetes is among the top 10 causes of death worldwide, and its prevalence is increasing more rapidly in low-income countries (LICs) and middle-income countries (MICs) than in high-income countries (HICs). Diabetes mortality rates also rose by 3 percent globally between 2000 and 2019 (WHO, 2023c). The WHO launched the [Global Diabetes Compact \(<https://openstax.org/r/whointa>\)](https://openstax.org/r/whointa) in 2021, an initiative to reduce diabetes rates and improve diabetes prevention and care. The focus of the compact is on LICs and MICs. Additionally, the World Health Assembly endorsed global health diabetes targets that are to be achieved by 2030. The targets are intended to reduce the risk of diabetes and provide people worldwide with equitable care (WHO, 2022c).

Cancer

Cancer is the leading cause of death globally. Its most prevalent forms are breast, lung, colon and rectal, and prostate cancer. As noted, approximately one-third of deaths from cancer are related to modifiable risk factors, such as tobacco use, obesity, harmful alcohol consumption, physical inactivity, and a diet low in fruit and vegetable intake. Approximately 30 percent of cancers in LICs and MICs are caused by infections such as the human papillomavirus (HPV) and hepatitis. The WHO urges governments to develop standards and tools to guide the planning and implementation of interventions for prevention, early diagnosis, screening, preventive vaccines, and treatment for adult and child cancers. Improved access to care is a critical component of this initiative. Comprehensive cancer treatment is available in 90 percent of HICs but only 15 percent of LICs (WHO, 2022a).

Malaria

Malaria is a life-threatening illness mostly found in tropical countries and spread by certain types of mosquitoes ([Figure 4.5](#)). Although it is preventable and curable, the incidence of malaria and its associated deaths are increasing. From 2020 to 2021, at the height of the COVID-19 pandemic, the incidence of malaria increased by 13 million cases, and there were 63,000 more deaths. Nigeria, the Democratic Republic of the Congo, the United Republic of Tanzania, and Niger account for over half of malaria deaths worldwide. Vector control is an essential aspect of preventing malaria; however, it is being threatened by resistance to insecticides. The WHO recommends the RTS,S/AS01 malaria vaccine for children, which significantly reduces malaria and its deadly sequelae. The WHO's *Global Technical Strategy for Malaria, 2016–2030* is a guide for malaria control and elimination that can countries can use as they strive to reduce or eliminate this public health threat (WHO, 2023b).

FIGURE 4.5 Research to discover new interventions to prevent or limit the spread of malaria is ongoing. (credit: “U.S. Army medical researchers take part in World Malaria Day 2010, Kisumu, Kenya April 25, 2010” by Rick Scavetta/U.S. Army Africa Public Affairs/Flickr, CC BY 2.0)

How Global Disease Estimates Support Challenges

The GBD is an important component in identifying health priorities worldwide, as well as trending the data to determine if health-related issues improve over time. The data provide a comprehensive overview of mortality and disability throughout the world and quantify losses related to hundreds of diseases, injuries, and risk factors. The GBD looks at both prevalence, or the number of people with a condition, and the relative harm that the condition causes. The data can then be used at global, national, and local levels to improve health care systems and address health care disparities (IHME, 2020).

Intersection of Health in America with Global Health

The United States has engaged with global health activities for over a century and contributes more funds to international health programs than any other country. The investment of the United States in global health is important not only from a humanitarian standpoint for other countries but also because it protects the health and well-being of Americans. The health and safety of countries worldwide are more closely linked than ever before. Travel provides opportunities for people around the globe; however, it also increases exposure to health risks. Global health issues like climate change and communicable diseases know no boundaries. The COVID-19 pandemic demonstrated the impact of an infectious disease on not only the health but also the economy of the world. Improvements in global health mandate a shift from independence to interdependence. Countries that identify and exchange best practices and strategies strengthen global health and human services systems (HHS, 2019).

The Nurse's Role in Global Health

All nurses, not only those who work as part of an international health care team, have a professional obligation to understand global health issues and health care priorities. It is important for nurses to develop an understanding of SDGs and global health priorities, as they are connected to local and national concerns. Infectious diseases, for example, do not recognize borders, as was evident during the rapid global spread of COVID-19 during the pandemic. Chronic diseases such as cancer have common risk factors regardless of geographic location, and all nurses must support health promotion initiatives to improve health outcomes. Nurses are also well positioned to lead efforts in global health due to their knowledge of population-based care (Salvage & White, 2020).

4.5 Global Public Health Security

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 4.5.1 Define global health security.
- 4.5.2 Describe interventions used to promote public health security.
- 4.5.3 Discuss the interconnectedness of population health across borders.
- 4.5.4 Describe the nurse's role in public health security.

Infectious diseases are a threat everywhere in the world. Global health security refers to public health systems that work to prevent, detect, and respond to these threats. In the United States, the CDC works to protect the American people's health, safety, and security and fight global health threats worldwide. The prevalent global health security risks include the following (CDC, 2022c):

- Emergence and spread of new infectious diseases
- Ability of diseases to spread related to the increased globalization of travel and trade
- Increasing drug-resistant, disease-causing pathogens
- Risk of accidental release, theft, or unlawful use of dangerous pathogens

The Global Health Security Agenda (GHSA) is an effort of more than 70 countries to protect the world from infectious disease threats (CDC, 2022f). The CDC works to strengthen the public health programs of other countries to reduce the risk of infectious disease outbreaks. It has invested in 19 partner countries to strengthen their public health readiness to contain infectious disease outbreaks at their source. The CDC is invested in the GHSA to promote the safety of the United States and the world, as there are more opportunities for disease to spread due to global travel. Closing gaps in preparedness is a role of the CDC that protects the world's health and economic and political stability (CDC, 2021d, 2022d).

Global Public Health Security Interventions

The CDC's efforts to promote public health security are focused on four interventions: surveillance systems, laboratory systems, emergency management, and workforce development. The CDC also works with other government agencies within the United States, such as the Office of Global Affairs (OGA), as well as ministries of health and international organizations to meet global health security goals (CDC, 2021d).

Surveillance Systems

Surveillance systems allow countries to identify risks and quickly detect and stop outbreaks of infectious diseases. In the United States, the National Notifiable Diseases Surveillance System (NNDSS) enables all levels of public health to report notifiable infectious, and some noninfectious, diseases. The data obtained by the NNDSS are used within the United States and can also be shared internationally. Limitations of surveillance systems include variations in reporting practices, both nationally and globally, and missing data from individuals who do not seek medical care. Resources, such as the availability of diagnostic testing facilities or the ability to test for new disease entities, also affect the validity and usefulness of case reports (CDC, 2022g). [Pandemics and Infectious Disease Outbreaks](#) discusses disease surveillance in more detail.

Laboratory Systems

Laboratory systems are an important component of public health security, as they allow for the detection of pathogens that cause disease, outbreaks, and death. Reducing the spread of disease and death is possible when a pathogen is identified quickly, as confirmation allows health care workers to respond with the appropriate treatment and prevention methods efficiently. As with surveillance systems, limitations of laboratory systems include factors such as the availability of diagnostic testing facilities and the ability to test for new disease entities. At the beginning of the COVID-19 pandemic in 2020, for example, the capacity for SARS-CoV-2 testing was limited, and the CDC advised a priority-based approach based on factors such as age, occupation, and morbidity. Another concern with COVID-19 testing was that limited data were available on the accuracy of the rapidly developed tests. These limitations, in turn, affected the validity of data obtained through surveillance systems (Goldstein & Burstyn, 2020). The WHO is reviewing the health emergency preparedness, response, and resilience (HEPR) process in light of the knowledge gained during the COVID-19 pandemic (WHO, 2022f).

Emergency Management and Response

Emergency management and efficient response to infectious disease threats are important public health security interventions. Countries must have knowledge and resources, such as emergency operations centers, to mount rapid, coordinated responses to infectious disease outbreaks. The United States and 19 partner countries have a Public Health Emergency Operations Center (PHEOC) that coordinates the response to an emergency or public health threat. Additionally, most of those 19 countries have personnel trained by the CDC's Public Health Emergency Management (PHEM) Fellowship course. Coordinated efforts within and between countries are important in reducing the potential for a local outbreak to become a pandemic (CDC, 2021c, 2021d; WHO, 2022e). [Principles of Disaster Management](#) discusses the nurse's role in emergency response in more detail.

Workforce Development

Global health security requires each country to have well-trained, highly skilled teams to investigate potential outbreaks and intervene quickly. The CDC has established the Field Epidemiology Training Program (FETP) to train what it refers to as "disease detectives" in more than 80 countries around the globe (CDC, 2023b). Many of these countries have expanded their programs since partnering with the CDC. The CDC also has between 350 and 400 experts who can be deployed in response to a public health emergency within 72 hours of the crisis, anywhere in the world (Knight, 2020).

THE DISEASE DETECTIVES STOP OUTBREAKS AT THEIR SOURCE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/4-5-global-public-health-security>\)](https://openstax.org/books/population-health/pages/4-5-global-public-health-security)

This video features the CDC's disease detectives as they investigate an outbreak of leptospirosis.

Watch the video, and then respond to the following questions.

1. How do the disease detectives conduct an investigation?
2. How does the CDC work with HHS during an investigation?

Interconnectedness of Population Health across Boundaries

Everyone is vulnerable to threats from infectious disease, which can spread nearly everywhere on Earth in as few as 36 hours (CDC, 2022d). The most significant risk from infectious disease occurs when novel diseases appear or when familiar diseases appear in novel geographic locations. COVID-19, for example, is a novel coronavirus. Illnesses that were eventually determined to be COVID-19 were first identified in Wuhan, China, in December 2019. COVID-19 spread rapidly, and the WHO declared it a global pandemic on March 11, 2020 (WHO, 2022f). From a public health standpoint, it is essential to understand the impact of emerging disease threats and outbreaks of familiar diseases on world health (CDC, 2022d).

Ebola

Ebola virus disease (EVD), or Ebola, is a rare form of hemorrhagic fever with a fatality rate that varies from 25 to 90 percent (Patel & Su, 2023). Ebola is transmitted by infected animals, the body fluids of infected persons, or items from infected persons that are contaminated with body fluids, such as clothing. It enters the body through human-to-human transmission via contact through the eyes, nose, or mouth or an opening in the skin. There are five identified strains of the Ebola virus species; four of them may cause the virus in humans (Patel & Su, 2023). Health care workers can become infected with Ebola if infection control precautions are not strictly followed. An effective vaccine is available only for the Zaire type of Ebola, and the treatment is supportive care and the use of antibodies (CDC, 2022c, 2023e; WHO, 2023e).

The first outbreak of Ebola occurred in 1976 in the Democratic Republic of the Congo (DRC, formerly Zaire) in a village near the Ebola River. There have now been more than 20 outbreaks of Ebola in 18 different countries, including the United States. In 2019–2020, the DRC experienced the second-largest recorded outbreak of Ebola (Patel & Su, 2023). Global health security interventions are imperative with a disease such as Ebola to contain the virus since transmission can occur even after the death of an individual, during burial practices (WHO, 2023e).

Tuberculosis

Tuberculosis (TB) is an infectious disease caused by the *Mycobacterium tuberculosis* bacteria. TB affects all age groups and occurs in every country in the world. In 2021, 10.6 million new cases of TB were diagnosed, resulting in more than 1.6 million deaths. TB is the second leading infectious cause of death worldwide, and although more than two-thirds of the new cases of TB in 2022 were in Bangladesh, China, the DRC, India, Indonesia, Nigeria, Pakistan, and the Philippines, it affects every country throughout the world. Multidrug-resistant TB (MDR-TB) is a public health threat because it is resistant to many drugs and is easily transmitted from person to person. Ending the TB epidemic by 2030 is among the health targets of the UN SDGs. The WHO is providing global leadership to end TB and setting strategic priorities, including monitoring and reporting on the current global, regional, and country-level epidemic progress (WHO, 2023f).

Human Immunodeficiency Virus

Human immunodeficiency virus (HIV) is an infection that affects the body's immune response. Acquired immunodeficiency syndrome (AIDS) is an advanced form of the disease. The first published report of what would be identified as HIV and AIDS was in 1981 (CDC, 2001), and more than 40 years later it remains a major global public health issue. There is ongoing transmission of HIV globally, compounded by the concerning trend of increasing transmission reported by some countries. In 2021, 1.5 million people were diagnosed with HIV, and 650,000 people died from HIV-related causes. Approximately 40 million people were living with HIV at the end of 2022, with two-thirds residing in the WHO African region. In 2022, 630,000 people died from HIV-related causes, and 1.3 million people acquired HIV. WHO global HIV strategies align with the SDG target of ending the HIV epidemic by 2030. Contracting both HIV and TB is significant, as nearly all HIV-positive people with TB will die (WHO, 2023d).

The Nurse's Role in Public Health Security

The role of the nurse in public health security is significant, and active participation is critical. Writing, updating, reviewing, and exercising emergency response plans are key, along with collaborating with other community entities in the event of an actual emergency.

The nurse must be knowledgeable about their agency's security plan and chain of command. For example, when a biological agent has manifested, the nurse can provide the public with fact sheets to disseminate valid health information. This also includes responding to health consequences of biological agents.

A suspected bioterrorist event may require the nurse to dispense vaccines, antimicrobials, and antitoxins or obtain other resources from HHS's Strategic National Stockpile (Administration for Strategic Preparedness and Response, n.d.). Nurses may also assist in shelters, schools, or places with vulnerable populations. Additionally, psychological support by the nurse may be required to care for the victims, the public, and the workers who are responding to and working with the bioterrorism event (Rowley & Barton, 2005). Both [Pandemics and Infectious Disease Outbreaks](#) and [Principles of Disaster Management](#) discuss bioterrorism in more detail.

Chapter Summary

4.1 Defining Health

Health is a state of complete physical, mental, and social well-being and wholeness. Social determinants that affect health outcomes include access to health care, a safe environment, healthy food and habits, and having social support for one's mental health. Public health nursing aims to improve health outcomes of the population by focusing on health promotion and disease prevention.

4.2 Performance Metrics

A population health measure or metric is an indicator that reflects the quality of a group's overall health and well-being. Life expectancy at birth, morbidity, mortality, and premature death are examples of population health outcome measures. Summary measures of population health combine data from the basic metrics, such as mortality and nonfatal disease outcomes, to obtain a single numerical statistic.

4.3 Health in America

The United States has the highest health care spending compared to peer countries but has worse health outcomes. Healthy People 2030 identifies high-priority health issues and challenges, which are referred to as leading health indicators (LHIs). LHIs are objectives that cover the lifespan and allow for the assessment and promotion of health at the community, state, and national levels. Mortality trends guide the development

Key Terms

burden of disease the impact of a health problem based on population health metrics, or indicators, that refer to valid, reliable, and comparable measures of health status

disability-adjusted life years (DALYs) the sum of years lost to a disease or health condition (the YLLs and YLDs), with each DALY representing the loss of one year of full health

Global Burden of Disease a study conducted by the Institute for Health Metrics and Evaluation (IHME) that reflects the current health care needs and challenges worldwide

health a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity

health disparities preventable differences in experiencing diseases, injuries, or opportunities

health equity the expectation that everyone has a fair opportunity to attain their highest level of health

health indicators health-related measures of data

of public health policies.

4.4 World Health Statistics

World health statistics are important to health care on a global basis. The results of statistical measurements indicate that people continue to live longer and live more years in good health. Health inequalities that take a toll on life and health are present in areas that do not have adequate resources. United Nations (UN) member countries developed sustainable development goals (SDGs) to create a more fair, just, and equitable world. SDGs are a call to action to address global challenges such as poverty, inequality, and climate change and promote peace and justice.

4.5 Global Public Health Security

Global public health security functions to prevent, detect, and respond to security threats. In the United States, the CDC works to protect the American people's health, safety, and security and fight global health threats worldwide.

The CDC's efforts to promote public health security focus on four interventions: surveillance systems, laboratory systems, emergency management, and workforce development. The CDC also works with other U.S. government agencies, such as the Office of Global Affairs (OGA), and with ministries of health and international organizations to meet global health security goals.

that are used to quantify and track an individual's health status

health outcome a change in the health status of an individual, group, or population that is attributable to a planned intervention or series of interventions, regardless of whether such an intervention was intended to change health status

health-related quality of life (HRQL) the perceived physical and mental well-being of an individual or group

Healthy People 2030 an initiative of the U.S. Department of Health and Human Services to improve the health and well-being of all people in the United States that has produced a list of high-priority health issues and challenges focused on the year 2030

incidence the number of new cases of a disease over a given time frame

leading health indicators (LHIs) high-priority, modifiable issues addressing social determinants of

health, health disparities, and health equity that have a significant effect on health outcomes

morbidity the state of being symptomatic or unhealthy due to a disease or condition; usually represented or estimated using prevalence or incidence

mortality rate the number of deaths in a specified time frame

population health outcomes broad topics related to a larger group or target population, such as mortality rates, life expectancy rates, prevalence of chronic conditions, or quality of life

prevalence the proportion of a population with a disease or condition over a given timeframe

quality-adjusted life years (QALYs) the months or years of reasonable quality that an individual may gain following medical treatment for a condition

social determinants of health (SDOH) non-health

factors such as socioeconomic status, education, or environment that affect health

sustainable development goals (SDGs) a call to action to address global challenges such as poverty, inequality, climate change, peace, and justice; aimed at all countries, including those that are developed and those that are developing

well-being the subjective perception that life is going well; is important from a public health perspective, as it is an outcome

years of healthy life lost due to disability (YLD) the number of healthy years one might lose from their life due to disability or sickness

years of life lost (YLL) a measure of premature mortality that considers both the frequency of death and the age at which it occurs, calculated by multiplying number of deaths by a standard life expectancy

Review Questions

- The public health nurse is examining the number of maternal deaths in a certain year. Which rate is the nurse studying?
 - Crude deaths
 - Morbidity
 - Mortality
 - Proportional population
- Which factor should the community health nurse take into account when assessing an individual's social determinants of health?
 - Genetic influences
 - Exercise habits
 - Nutritional intake
 - Level of education
- Which source of data would a community health nurse utilize during a community assessment to determine the births, deaths, marriages, health, and diseases in a certain county?
 - Morbidity report
 - Service utilization
 - Population survey
 - Vital statistics
- Which outcome would the community health nurse measure to evaluate the health of a population?
 - Blood pressure readings of individuals in the community
 - Home blood glucose levels monitored by clients with diabetes
 - Mortality rates in the community
 - Percent of high school students who attend college
- Which definition of health would the nurse attribute to a client who perceives themselves as healthy despite taking medication for hypertension?
 - Health is the absence of disease.
 - Health is the full return to wellness.
 - Health is a state of improving well-being.
 - Health is an internal state of balance and well-being.

6. The nurse is explaining to a client that smoking cessation will add years of quality to their life. Which population health metric is the nurse describing?
 - a. Years of healthy life lost due to disability
 - b. Disability-adjusted life years
 - c. Quality-adjusted life years
 - d. Years of life lost
7. Which indicator is the nurse utilizing when considering the effects of diseases that people in a population are living with?
 - a. Morbidity
 - b. Mortality
 - c. Burden of disease
 - d. Prevalence
8. Which current health trend data will the population health nurse utilize to develop health education programming?
 - a. Heart disease is the leading cause of death in most ethnic and racial groups.
 - b. Deaths from cancer have increased in the last two decades.
 - c. Deaths from stroke are decreasing in all ethnic and racial groups.
 - d. Unintentional accidents are the fourth leading cause of death in individuals aged 1 to 44 years.
9. A nurse is volunteering for a global nongovernmental organization whose work addresses the United Nation's sustainable development goals (SDGs). Which statement about the SDGs is accurate?
 - a. SDGs have been impacted by the climate crisis.
 - b. The focus of SDGs is on developing nations.
 - c. Progress on SDGs is reported every 5 years.
 - d. Each country has its own individualized SDGs.
10. Which trend in mortality in the United States over the past century would the nurse utilize to develop public health campaigns?
 - a. Life expectancy has increased, and rate of death has decreased.
 - b. Life expectancy and rate of death have remained unchanged.
 - c. Life expectancy has increased, and rate of death has also increased
 - d. Life expectancy has decreased, and rate of death has also decreased.

CHAPTER 5

Demographic Trends and Societal Changes

FIGURE 5.1 Immigration and naturalization partly drive changing demographics. Other factors include the aging population, regional and national employment trends, and changes in healthcare. (credit: modification of work "Naturalization Ceremony" by Utah Reps/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 5.1 Demographic Factors
 - 5.2 Health Care Consumer Behavior
 - 5.3 Virtual Care and Technology
 - 5.4 Health Care Workforce
-

INTRODUCTION Michael is a public health nurse who works at a free clinic in the community where he grew up and still lives. The community Michael's clinic serves includes a large immigrant population as well as a high percentage of older adults. A consortium of local clinics in Michael's area recently received a grant from the Health Services and Resources Administration (HRSA)—which operates under the U.S. Department of Health and Human Services (HHS)—to work toward increasing the number of minorities who receive care at these local clinics. As a participant in the consortium, Michael prepared a flyer about the free clinic. The clinic has been recruiting nurses that represent minority ethnic groups in the community, so Michael included photos of the diverse staff to help increase trust in the clinic's health care. As a public health nurse, Michael has the opportunity to improve access to health care and nutrition resources for his community.

This chapter will discuss demographic shifts in the United States and the unique opportunities they present to advance technology and to improve policy, consumer behavior, and the health care workforce.

5.1 Demographic Factors

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 5.1.1 Define demographics.
- 5.1.2 Describe the fastest-growing demographics in the United States.
- 5.1.3 Discuss characteristics of underrepresented populations.
- 5.1.4 Examine how projected population changes challenge public health policies and the implications for health care services.

Demographics are statistical data regarding the characteristics of the people living in a particular place, describing them based on categories such as age, race, ethnicity, sexual orientation, gender identity, ability, education level, income level, and marital status. Individuals belong to many demographic groups. For example, a person may belong to one group based on age, another based on race, and a third based on geographic location. This section examines demographics, focusing on rapidly growing underrepresented populations and on how the growth of these populations affects both public health policies and the provision of health care services.

Fastest-Growing Demographics

U.S. Census Bureau forecasts indicate that the United States will continue to experience significant demographic shifts in the next 40 years. By 2060, the U.S. population is expected to increase by 79 million people (U.S. Census Bureau, 2020), and changing demographics will have major implications for the national health care system. Community health and public health nurses must prepare to serve these changed populations. A more diverse nursing workforce will lead to better health outcomes for populations (American Association of Colleges of Nursing, 2023). This section reviews the most rapidly expanding population groups within the United States.

Baby Boomers

One way to categorize populations is by generation, a period spanning about 20 to 30 years that includes everyone who is born and lives their lives at approximately the same time, experiencing similar social and cultural events. Until recently, baby boomers, or the generation born from 1946 to 1964, made up the largest generation in the United States—76 million births—and 71.6 million living adults in 2019 (Fry, 2020). As this large demographic group ages, the number of individuals over the age of 65 continues to increase. For example, although older adults represented 8 percent of the total population in 1950, they made up 16 percent of the population in 2020 and are projected to represent nearly 25 percent of the total population in 2060 (see [Figure 5.2](#)) (Centers for Disease Control and Prevention [CDC], 2022d).

The U.S. Census Bureau estimates that by 2030 all individuals in the United States categorized as baby boomers will be over 65 years old, marking a significant shift toward an older average age in the U.S. population (America Counts Staff, 2019). The growth of the baby boomer population is significant for nurses and other health care professionals because older adults tend to have a higher prevalence of health issues and chronic diseases, such as Alzheimer's disease, diabetes, hypertension, and arthritis, that are related to aging (CDC, 2022d). As the proportion of older adults in the population increases, the incidence of age-related health conditions and deaths will also increase. Consequently, the need for health care services in nursing homes, long-term care, and home health care facilities in the United States will grow.

The Aging of the U.S. Population

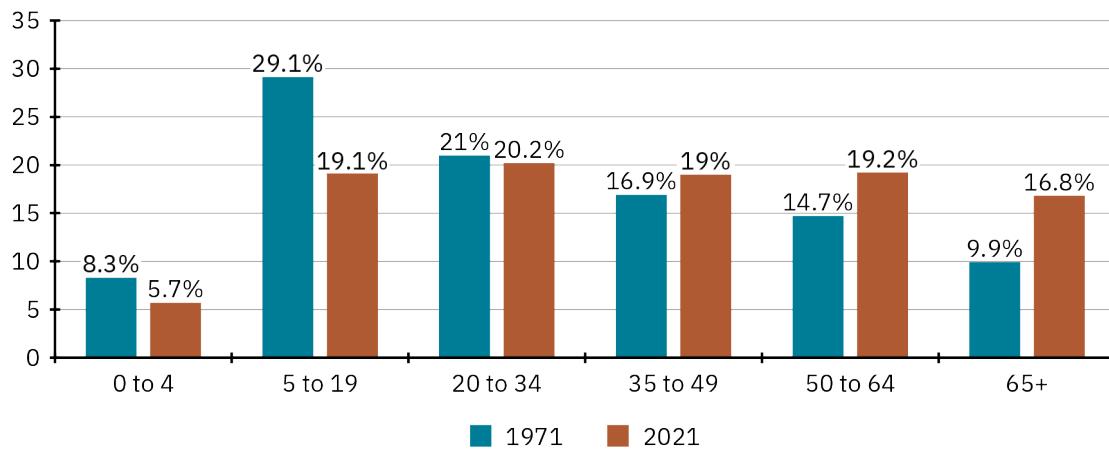

FIGURE 5.2 The number of individuals over the age of 65 in the U.S. population is growing. (data source: U.S. Census Bureau; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Racial and Ethnic Minorities

Another projected demographic change in the U.S. population is a shift in the numbers of racial and ethnic minorities in relation to the population as a whole. **Ethnic minorities** are population groups with a shared culture, tradition, religion, language, history, or other factors living in communities or areas where most people are from a different

ethnic group. Between 2020 and 2060, the U.S. Census Bureau predicts major changes in the racial and ethnic diversity of the U.S. population. For example, the number of non-Hispanic White individuals is expected to decrease dramatically. In 2020, there were approximately 199 million non-Hispanic White individuals in the United States; that number is expected to fall to approximately 179 million by 2060, a 10 percent decrease. The decline in the non-Hispanic White demographic is related to a decrease in overall births and an increase in deaths over time.

During the same 40-year period, individuals who identify as two or more races are projected to be the fastest-growing racial or ethnic group in the United States. The U.S. Census Bureau estimates that Asian people will make up the second fastest-growing ethnic group, and Hispanic people will be the third fastest. The projected increase in the number of individuals who identify as Hispanic is attributed to an increase in the number of children born to parents who identify as Hispanic in the past decade, while the projected increase in net international migration is the primary driver for an increase in the number of individuals who identify as Asian. The U.S. Census Bureau also estimates that the population of individuals who are considered foreign-born will increase from 44 million in 2016 to approximately 69 million in 2060, making up 17 percent of the U.S. population (2020).

For nurses and other health care professionals, these rapidly changing demographics are significant because they have implications for the prevalence of disease and **health disparities**. The CDC defines health disparities as “preventable differences in the burden of disease, injury, violence, or opportunities to achieve optimal health that are experienced by socially disadvantaged populations” (CDC, 2020a, para. 1).

Heart disease, cancer, diabetes, and stroke are the most common causes of illness, disability, and death in the United States (CDC, 2022a). **Underrepresented populations**, such as ethnic minorities, tend to be impacted the most by **chronic diseases**—conditions like hypertension, diabetes, kidney disease, heart disease, and cancer—that individuals live with for a year or more that require ongoing medical attention, limit the activities of daily living, or both. Underrepresented populations are defined as subgroups within a population, often identified by race, ethnicity, age, sex, gender, sexual orientation, or socioeconomic status, whose representation in society is disproportionately low relative to their numbers (National Institutes of Health [NIH], 2023b). Chronic diseases affect certain racial and ethnic groups more than others:

- Between 2017 and 2018, diagnosed diabetes prevalence was higher among American Indians/Alaska Natives, people of Hispanic origin, and non-Hispanic Black people than among White people (CDC, 2020c).
- In 2018, Asian people comprised 6 percent of the U.S. population but accounted for approximately 2 percent of new HIV cases (CDC, 2020b).
- Asian/Pacific Islanders have tended to experience the highest rate of hepatitis B when compared with other ethnic groups. As such, rates of hepatitis B-related mortality remain higher among Asian/Pacific Islanders than among their ethnic counterparts (CDC, 2020b).
- In 2018, the rate of tuberculosis among Asian people was 31 times higher than all people reported as having been diagnosed with tuberculosis nationwide (CDC, 2020b).

Black and Hispanic people and Alaska Natives experience worse health outcomes on several measures when compared with their White counterparts (NIH, 2023b):

- Alaska Natives, Hispanic people, and American Indians are at higher risk of being uninsured (Tolbert et al., 2022).
- Black, Hispanic, and Asian adults were less likely to receive care for mental health conditions as of 2021 (Hill et al., 2023).
- Approximately six in 10 Hispanic, Black, and Alaska Native adults did not receive a flu vaccine in the 2021–2022 flu season compared with less than one-half of White adults (Hill et al., 2023).
- Life expectancy at birth was shorter for Alaska Native people and Black people between 2019 and 2021 (Hill et al., 2023).
- In 2021, infant mortality rates were twice as high among Black people and Alaska Native people (Hill et al., 2023).
- In 2021, Black and Alaska Native women experienced the highest rates of death related to pregnancy (Hill et al., 2023).
- In 2021, Black and Hispanic children were more than twice as likely to experience food insecurity (Hill et al., 2023).

HEALTHY PEOPLE 2030

Reduce the Proportion of Adults Who Don't Know They Have Prediabetes

According to Healthy People 2030, approximately 38 percent of individuals living in the United States, age 18 and older, have undiagnosed prediabetes. The goal of this Healthy People 2030 objective is to [decrease the proportion](https://openstax.org/r/healthreduce) (<https://openstax.org/r/healthreduce>) of American adults who have prediabetes from the baseline of 38 percent in 2013 to 33.2 percent by 2030. Healthy People 2030 discusses resources for individuals such as weight loss, healthy eating, and increased physical activity to reduce the risk of prediabetes.

According to the CDC (2022b; 2020c), African Americans, Hispanic/Latino Americans, and American Indians, Pacific Islanders, and some Asian Americans are at elevated risk of developing prediabetes.

(See Office of Disease Prevention and Health Promotion [ODPHP], 2023c.)

UNFOLDING CASE STUDY

Part A: Demographic Factors

Read the scenario, and then answer the questions that follow.

Jose is a 53-year-old Hispanic male who has presented to the clinic with anxiety and with chest pain radiating to the right arm. Jose was recently let go from his job and has not been able to find employment. He is accompanied to the clinic by his wife and his mother. Jose indicates that he does not like coming to the doctor's office, and he becomes more anxious as the nurse completes his health assessment. His vital signs are as follows:

- Blood Pressure: 126/82 mm Hg
- Respirations: 18 breaths/minute
- Heart Rate: 130 beats/minute
- Oxygen Saturation: 98 percent on room air

Other findings from the nurse's health assessment of the client are as follows:

- Neurological: Within normal limits.
 - Respiratory: Lungs clear to auscultation.
 - Cardiovascular: Increased heart rate, but normal heart sounds. No peripheral edema noted.
 - GI: Within normal limits.
 - GU: Within normal limits.
 - Pain: Radiating to the right arm 5 on a scale of 1–10.
1. When assessing Jose, what factors about his ethnic background should the nurse consider?
 - a. The client is at a higher risk for certain health conditions because of his ethnic background.
 - b. The client has the same risk for certain health conditions as anyone else his age.
 - c. The client is a member of a minority group that is decreasing in numbers over time.
 - d. The client is a member of a minority group that is eligible for additional health-related resources.
 2. How can Jose's employment status potentially affect his health?
 - a. He will be covered by Medicaid, so there should be no long-term effects.
 - b. He can continue to receive health care in the local emergency department.
 - c. He is more likely to be affected by a health disparity.
 - d. His temporary unemployment status should not permanently affect his health.

Vulnerable Populations

According to the National Collaborating Centre for Determinants of Health (NCCDH), “vulnerability occurs when people are exposed to multiple layers of marginalization, including barriers to social, economic, political, and environmental resources that overlap to increase the risk of poor health. Individuals and communities are

vulnerable to, live in vulnerable conditions or are forced into vulnerability rather than being labeled as vulnerable people/populations/groups” (NCCDH, 2023, para. 1). Ethnic and racial minorities are examples of **vulnerable populations** as many individuals within these groups are at risk of experiencing health disparities. Individuals experiencing poverty—many of whom identify as members of ethnic or racial minorities—are another demographic at risk of poor health outcomes related to lack of access to health care. For example, a 2020 report on income and poverty in the United States revealed the following (Shrider et al., 2021):

- Between 2019 and 2020, real median household income decreased 2.9 percent to \$67,521.
- The total number of people with earnings decreased by 3.0 million, and the number of individuals who worked full-time year-round decreased by 13.7 million between 2019 and 2020.
- There was a 1.2 percent decrease in real median earnings for all workers.
- The official poverty rate increased from 10.5 percent in 2019 to 11.4 percent in 2020.
- In 2020, 37.2 million people were living in poverty, up from 33.9 million in 2019.

Sexual and gender underrepresented populations, which “include, but are not limited to, individuals who identify as lesbian, gay, bisexual, asexual, transgender, Two-Spirit, queer, and/or intersex” (NIH, 2023a, para. 2), are another vulnerable population that is growing. The number of individuals identifying as lesbian, gay, bisexual, or transgender rose significantly between 2010 and 2020. As of 2017, there were approximately 11.4 to 12.2 million adults living in the United States who identified as lesbian, gay, bisexual, or transgender (National Library of Medicine, 2020).

The population of individuals with disabilities is another growing vulnerable population. Between 2008 and 2019, rates of disability among children under age 18 increased by 0.4 percent (Young & Crankshaw, 2021). Children who identified as American Indian and Alaskan Natives and those living in poverty had the highest rates of disability (Young & Crankshaw, 2021). In its [Annual Report on People with Disabilities in America](https://openstax.org/r/disabilitycompendium) (<https://openstax.org/r/disabilitycompendium>), the University of New Hampshire Institute on Disability (2023) states that the percentage of Americans with disabilities increased from 13.2 percent in 2019 to 13.5 percent in 2021.

For nurses and other health care professionals, these changing demographics are significant because they present challenges in areas across society, including in the workforce, education systems, and health care systems.

Vulnerable populations tend to have more health issues such as preventable diseases (e.g., diabetes, hypertension, and obesity) and poor access to care, which leads to increased mortality (deaths) and morbidity rates (diseases). An increase in mortality and morbidity reflects increased health disparities (American Association of Colleges of Nursing, 2023). Members of the lesbian, gay, bisexual, transgender, queer/questioning, intersex, and asexual/aromantic/agender plus other unknowns (LGBTQIA+) community—particularly youth—are at increased risk for negative health and life outcomes related to discrimination and stigma. The risk of suicide and substance misuse is high within this age group (CDC, 2023b). Individuals with disabilities are more likely to smoke and have obesity, heart disease, and diabetes. One in four adults in this population is also less likely to have a dedicated health care provider or receive an annual check-up (CDC, 2019a).

THE ROOTS OF HEALTH INEQUITIES

What Causes Health Inequities?

[Access multimedia content](https://openstax.org/books/population-health/pages/5-1-demographic-factors) (<https://openstax.org/books/population-health/pages/5-1-demographic-factors>)

The World Health Organization (WHO) defines health inequities as “systematic differences in the health status of different population groups” (2023, para. 2). Health inequities are the result of human-made systems that favor one group over another. As a result, an unequal distribution of power occurs. The following have been identified as the structural root causes of health inequities: racism, sexism, classism, xenophobia, heterosexism, and ableism. These inequities can occur at the institutional level (how organizations treat others), interpersonal level (individuals’ behaviors toward each other), and the internal level (how individuals view themselves). Watch the video for more information about the causes of health inequities.

In addition to experiencing more health issues, members of underrepresented communities tend to distrust the health care system because of racism, bias, and perceived mistreatment. For example, in a Kaiser Family Foundation survey, 78 percent of individuals who identified as White said they trusted their doctors, although only 59 percent of those who identified as Black said they trusted theirs (Hamel et al., 2020).

As discussed in [Structural Racism and Systemic Inequities](#), much of this distrust is due to systemic racism—the institutional unfair treatment of individuals based on race—and discrimination against racial minority populations in the United States. The perception by members of underrepresented communities that racism will be present often leads this population to choose not to seek health care. The resulting poor health outcomes further exacerbate health disparities between groups within a population. Such disparities are especially present in cancer screening, neonatal care, pain management, end-of-life care, and the treatment of cardiovascular disease (Huzar, 2021).

Individuals tend to have better health outcomes when they receive care from providers who are familiar with their culture (Nair & Adetayo, 2019). Health care providers should work toward developing greater cultural competence—the ability to understand and work with people of cultures other than one's own—which in turn increases trust within communities. The box below provides some suggestions for strategies nurses can use to increase client trust. Also see [Culturally and Linguistic Responsive Nursing Care](#) and [Managing the Dynamics of Difference](#) for more information on this topic.

GUIDELINES FOR INCREASING TRUST WITH CLIENTS

- Learn about the client's culture and ensure it is central in every aspect of the client's care.
- Include the client and their family in the care process.
- Work to build trust with your client before and during the client care process.
- Be open and transparent with the client when communicating.
- Assess whether the client understands what you have taught them (health literacy).
- Be mindful of the degree to which the client has access to health care resources, and ensure you have mechanisms in place to address barriers, such as transportation, housing, and health insurance.
- Involve the interdisciplinary team in the client's care to ensure all aspects of the client's life and health issues are addressed. This would include professionals such as the physician, social workers, nutritionist, and health educators.

(See The Institute for Functional Medicine, 2023.)

Needed Policy Changes

To provide appropriate care to a changing population, policies and programs devoted to achieving health equity must be developed. **Health equity** refers to “the state in which everyone has a fair and just opportunity to attain their highest level of health” (CDC, 2022g, para. 1).

The CDC's [Office of Health Equity](https://openstax.org/r/cdchequity) (<https://openstax.org/r/cdchequity>) is on the front lines of achieving health equity through its CORE Strategy, which is an integration of health equity into every element of the work of the organization. CORE is an acronym for the following goals (CDC, 2023a):

- **C**ultivate Comprehensive Health Equity Science—The CDC Office of Health Equity will facilitate and accelerate the principles of health equity across all CDC programs, policies, and funding structures.
- **O**ptimize Interventions—The CDC Office of Health Equity will engage partners to address gender discrimination and gendered racism in the workplace.
- **R**einforce and Expand Robust Partnerships—The CDC Office of Health Equity will engage partners to mobilize around developing and implementing strategies to address health disparities and long-term health inequities, which includes the social determinants of health.
- **E**nance Capacity and Workforce Engagement—The CDC Office of Health Equity will work to diversify the public health workforce.

One health policy with which most people are at least somewhat familiar is the Patient Protection and Affordable Care Act of 2010, also known as the Affordable Care Act (ACA). The primary goals of the ACA are to (U.S. Department of Health and Human Services [HHS], 2023a):

- Improve the affordability of health insurance to more individuals ([Figure 5.3](#)).
- Expand the Medicaid program, a state-operated health insurance program for those who are living in poverty or are disabled.

- Provide support for medical care delivery methods that are designed to yield lower health care costs.

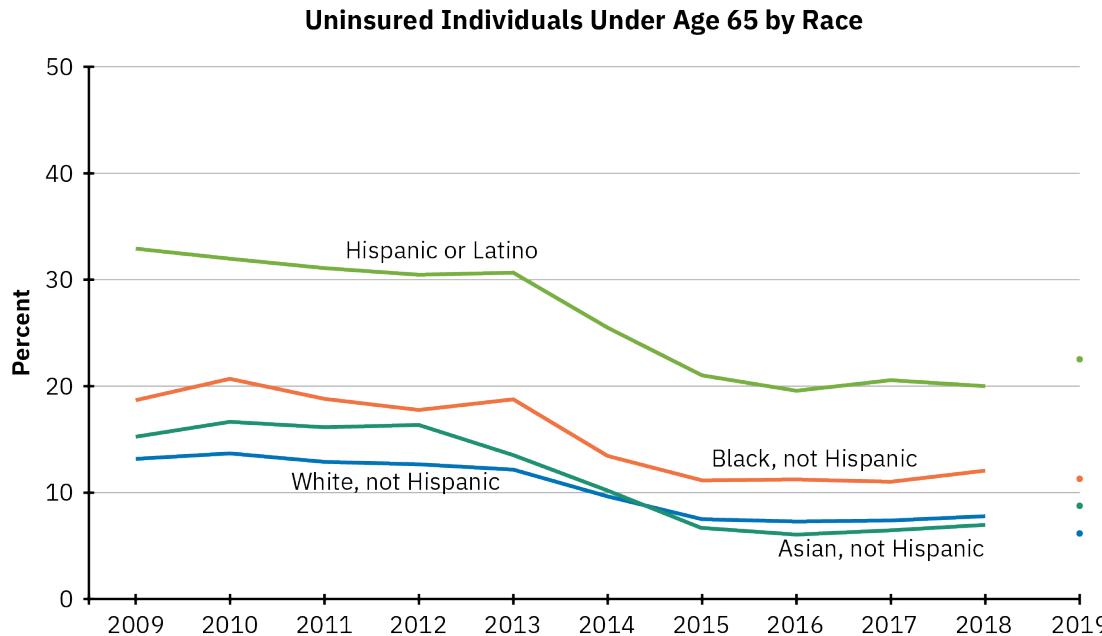

FIGURE 5.3 This graph shows the lack of health insurance among people in the United States under age 65 by race and Hispanic origin. (Those over age 65 are covered by Medicare and Medicaid.) (data source: National Center for Health Statistics, National Health Interview Survey [NHIS] and *Health, United States, 2020–2021*, <https://www.cdc.gov/nchs/hus/topics/health-insurance-coverage.htm>; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

5 THINGS ABOUT THE AFFORDABLE CARE ACT

[Access multimedia content \(<https://openstax.org/books/population-health/pages/5-1-demographic-factors>\)](https://openstax.org/books/population-health/pages/5-1-demographic-factors)

This video provides a brief overview of the ACA, the 2010 law that increases health insurance options and provides additional health care rights and protections to all citizens, improving access and reducing disparities.

Watch the video, and then respond to the following questions.

- How does the ACA protect clients with preexisting medical conditions?
- What are some preventive services covered by the ACA? How do such services improve clients' health?

Medicaid is a national program, jointly funded by each state and the Centers for Medicare and Medicaid Services (CMS, 2022), a federal agency. The program provides health coverage to the following populations: eligible low-income adults, children, pregnant clients, older adults, and people with disabilities. Medicaid is administered by individual states according to federal requirements. Each state independently determines its population's Medicaid coverage and eligibility; to be eligible, an individual must fall within a certain financial category. One outcome of the ACA was to lower Medicaid eligibility requirements, thus increasing opportunities for those needing it; each state determined whether to expand Medicaid.

As of 2023, 38 out of 50 states and the District of Columbia had adopted and implemented expanded Medicaid; Wyoming, Kansas, Wisconsin, Texas, Mississippi, Tennessee, Alabama, Georgia, South Carolina, and Florida chose not to adopt Medicaid expansion, and South Dakota and North Carolina had adopted expansion but had not implemented it (Rudowitz et al., 2023). States that chose to expand Medicaid experienced an average reduction in poverty of 0.917 percent, or approximately 690,000 individuals lifted above the federal poverty line (Chee, 2019; Zewde & Wimer, 2019). These expansion states experienced increased state revenue as well as cost savings in other government programs that provide services that overlap with Medicaid (Guth & Ammula, 2021). Hospitals and other health care providers in expansion states have seen their profits and revenues increase (Guth & Ammula, 2021). In the states that have not adopted the Medicaid expansion, individuals fall into the coverage gap where their income is too high to qualify for Medicaid but too low to qualify for subsidies offered by health insurance plans through the ACA Health Insurance Marketplace (Kagan, 2022). The uninsured rate in these states is almost double

the rate of uninsured in states that have expanded Medicaid (15.4 percent compared with 8.1 percent) (Rudowitz et al., 2023). If all states adopted the Medicaid expansion, approximately 3.5 million uninsured adults would become eligible for coverage (Rudowitz et al., 2023).

Medicare, a federal health insurance program, provides health insurance coverage to individuals over age 65 and to those with specific disabilities who are younger than 65. Different parts of Medicare cover different services. Medicare Part A pays for inpatient hospital visits, skilled nursing facilities, hospice care, and some home health care; Part B pays for some outpatient care, doctor's visits, and preventive services, and Part D covers the cost of prescription drugs (Medicare.gov, n.d.; Medicare Resources, 2023). Sixty-five million Americans receive insurance coverage through Medicare. This includes 57 million older adults and almost 8 million younger adults who have disabilities (Kaiser Family Foundation, 2023). Unlike Medicaid, Medicare is both funded and controlled by the federal government. To address the increasingly aging population—as well as increases in the number of individuals with disabilities—additional Medicare funding is necessary. By 2030, the percentage of American citizens who do not work and rely on those who are employed will exceed 70 percent. Medicare is expected to deplete its reserve by 2035 if the trend of the aging of America continues its current trajectory. In order for Medicare to continue providing for the growing number of recipients, policy change will be needed to fund the program.

5.2 Health Care Consumer Behavior

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 5.2.1 Examine how the availability of health care services influences consumer behavior.
- 5.2.2 Discuss how consumer confidence influences consumer behavior.
- 5.2.3 Explain how the cost of health care services affects consumer behavior.

A **health care consumer** is someone who makes use of health care services regardless of whether they pay for those services directly or those services are provided to them at no cost. Internal and external factors affecting health care consumers' behavior include:

- Availability of health care services and providers
- Consumer confidence
- Consumer loyalty
- Cost of health care services

Availability of Health Care Services

The availability of health care services and health care providers may be limited or absent, depending on where an individual lives. This is especially true for people who live in rural areas where the distance to the nearest clinic, hospital, or provider may be great and transportation to reach health care services may be a barrier related to cost or availability. Many rural regions of the United States have been experiencing severe shortages of primary care providers for decades (Rural Health Information Hub [RHIH], 2023), exacerbating health disparities as individuals without reasonable access to health care providers and services cannot adequately address health conditions or receive preventive care, such as screenings (CDC, 2022g).

Mental health care is essential to a population's health, yet there are additional barriers to accessing these services—particularly for disadvantaged groups. “**Mental health** includes a person's emotional, psychological, and social well-being. It affects how we think, feel, act, handle stress, relate to others, and make choices” (CDC, 2022c). The cost of mental health services has continued to rise in the United States over the last decade. According to Harvard Pilgrim Health Care (2023), “even prior to the pandemic in 2019, the cost of mental health treatment and services reached \$225 billion, up 52 percent from 10 years earlier.”

Ethnic minorities experience greater mental health disparities than the rest of the population (CDC, 2023c). This is often related to limited access to health care services as well as stigma and discrimination, which may prevent individuals from seeking care. **Stigma** is shame or disgrace attached to an individual's circumstance, background, personal traits, or associations. Often the result of ignorance or fear, stigmatization involves negative attitudes and beliefs toward people, which can also lead to discrimination (American Psychiatric Association (APA), 2023; Mayo Clinic, 2017). This stigma is especially acute in minority communities. For some populations, such as ethnic minorities and those struggling with chronic diseases, accessing mental health services is especially difficult. For

example, ethnic minorities tend to live in areas that lack treatment facilities or health care providers qualified to offer mental health services (CDC, 2022g). In addition, stigma related to mental illness tends to prevent individuals from seeking care (Mayo Clinic, 2017). The combination of stigma and limited access to health care services means that individuals living with mental illness may not seek care until their disease has advanced to the point that more expensive treatments or even institutionalization are required, which drives up the cost of caring for an individual living with a mental illness. [Caring for Populations and Communities in Crisis](#) provides more information on mental health.

Consumer Confidence

Consumer confidence refers to how individuals feel about health care services and providers. Confidence in the health care system can be compromised. For example, a history of structural racism and discrimination in the United States may lead members of some communities, such as communities of color, to distrust the health care system. People who distrust the system tend to avoid seeking the care they need to address health conditions, such as chronic diseases (CDC, 2022f; 2022g). Individuals who are concerned that they will not be able to communicate effectively with health care providers or navigate the complexities of the health care system due to language barriers, low health literacy, or both may be reluctant to seek care (RHIH, 2022). Consumer loyalty refers to an ongoing emotional relationship between an organization and its customers. Customers loyal to an organization tend to support its mission and utilize its services (Oracle, 2023). Based on this definition of customer loyalty and consumer confidence, it is possible to conclude that mistrust in the health care system may prevent individuals from seeking care, potentially further exacerbating health disparities (CDC, 2022g).

The COVID-19 pandemic highlighted the longstanding issue of a lack of trust in the health care system among ethnic minorities and other underrepresented populations, resulting in vaccine hesitancy despite higher rates of COVID-19 infections, deaths, and hospitalizations among this demographic (Shearn & Krockow, 2023). The rapid development of the COVID-19 vaccine caused many communities—such as Black, Hispanic, and immigrant communities—to grow increasingly distrustful of the health care system because of a history of unethical research practices in which minorities were mistreated. This significantly increased the level of anxiety among these groups and made many less likely to get vaccinated (Baker, 2020). A systematic review of the literature by Shearn and Krockow (2023) attributed three main themes related to COVID-19 vaccine hesitancy among ethnic and racial minority populations: institutional mistrust, lack of confidence in the vaccine development process, and lack of reliable information or messengers. In addition to the general history of racism and discrimination encountered by this population, many are aware of a history of previous mistreatment and unethical research practices by medical researchers, such as bias in assigning minorities to study groups in clinical trials. For this reason, some equated the rapid development of the COVID-19 vaccine with fears about medical experimentation, sterilization, or eradication. Individuals who reside in the United States without legal documentation expressed concerns that data related to their vaccination would be shared with immigration enforcement (Shearn & Krockow, 2023; Rusoja & Thomas, 2021).

Health Care Costs and Consumer Behavior

Cost determines if an individual can afford to pay for health care services. Those with limited income often must choose between health care and basic needs such as food and shelter. In this situation, they may choose not to seek health care services altogether, which further exacerbates health disparities related to chronic diseases such as diabetes, heart disease, and obesity (CDC, 2022g).

Cost of Health Insurance

Health care costs impact the behavior of individuals who lack the means to pay for health care services. For example, ethnic minorities, such as Hispanic and Black clients, tend to have higher rates of uninsured than their White counterparts. This is especially true of individuals living in rural and urban areas and of the “working poor,” individuals who do not make enough money to purchase health insurance but who make too much money to qualify for Medicaid (Commonwealth Fund, 2021). When individuals lack the means to pay for health care services, their use of health care services tends to decrease, which leads to more negative health outcomes for the client.

Cost of Prescription Drugs

The cost of prescription medications also affects consumer behavior. Prescription drug prices have risen steadily in the last two decades in the United States. According to a report by the American Association of Retired Persons

(AARP, 2021), every year since 2006, the cost of specialty prescription drugs has increased at a rate that far exceeds the general inflation rate. Such specialty medications are used to treat cancer, rheumatoid arthritis, multiple sclerosis, and other conditions and are used widely by older adults. Approximately three in 10 adults report not taking their medications as prescribed due to cost (Kirzinger et al., 2023). Among this group, 21 percent did not fill the prescription, 21 percent took an over-the-counter medication instead of getting the prescription filled, and 12 percent reported cutting the pills in half or skipping doses to save costs. Other common strategies clients use to decrease drug costs include using generic drugs, asking the health care provider to prescribe a different medication (a less expensive alternative, a higher dose that can be split in half, or a different form of the drug—a cream instead of a gel, for example), or trying alternative therapies (CDC, 2019b).

Cost of Delaying Care

According to the CDC (2022g), racial and ethnic minorities tend to be impacted by disease at greater levels than their White counterparts. The same can be said of older adults, who tend to have more health issues than their younger counterparts. In many cases—because of the cost of, mistrust in, or lack of easy access to health care services and providers in their communities—individuals may wait until their disease is more advanced before they seek health care. For example, a person who does not receive care during prediabetes may be impacted by kidney failure secondary to diabetes, which is far more expensive than preventing or even managing diabetes before it has damaged the kidneys.

The COVID-19 pandemic also ushered in a time of economic challenges. Job losses peaked during the pandemic, especially for minority populations who worked in low-paying industries impacted by pandemic-caused closures (Center on Budget and Policy Priorities, 2022). These job losses coincided with a rise in health care costs, which exacerbated the tendency of many ethnic minorities to not seek health care, contributing to negative health outcomes among groups who were already struggling before the arrival of the pandemic.

Cost of Disease Care

Ethnic minorities and older adults may also be more likely to be the recipients of public health insurance programs such as Medicaid and Medicare. The types and severity of health conditions experienced by these demographics make health care costs covered by government insurance programs even greater. For example, as the percentage of older adults in the United States grows, the dollars Medicare pays will continue to rise. This is especially true as the large numbers of aging baby boomers become eligible for Medicare at age 65.

When individuals lack adequate health insurance, they tend to use hospital emergency departments more frequently ([Figure 5.4](#)) (Udalova et al., 2022). Laws prevent health care organizations from turning clients away when they present to the emergency department. When individuals lack health insurance, health care organizations may have to provide uncompensated care, which leads to increased costs for the facility (American Hospital Association, 2023c). Individuals from underrepresented communities and those with lower incomes tend to use an emergency department for preventable care more than their counterparts in other communities (Udalova et al., 2022). Thus, the cost of paying for health insurance for underrepresented populations leads these populations to use the emergency department for services best addressed in another setting (Udalova et al., 2022).

FIGURE 5.4 Individuals who lack access to other health care providers or health insurance may seek treatment at a hospital emergency department. (credit: "Saratoga Hospital emergency entrance, Saratoga Springs NY" by Peter/Flickr, CC BY 2.0)

HEALTHY PEOPLE 2030

Reduce Emergency Department Visits for Nonfatal Injuries

According to Healthy People 2030, there were approximately 9,325 emergency department visits for nonfatal injuries per 100,000 people in 2017. To address this issue, Healthy People 2030 established a goal to [reduce the number of visits for nonfatal injuries \(<https://openstax.org/r/healthinjuries>\)](https://openstax.org/r/healthinjuries) to approximately 7,711 per 100,000 people by 2030. The most recent data from 2020 show this goal has been exceeded.

(See ODPHP, 2023b.)

5.3 Virtual Care and Technology

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 5.3.1 Examine key technology trends impacting delivery of care.
- 5.3.2 Describe how technology can advance cost-effective health solutions.
- 5.3.3 Assess the implications of technology for quality and safety of care.

According to the Health Care Information and Management Systems Society (2023, para. 4), “the use of technology increases provider capabilities and patient access while improving the quality of life for some patients and saving the lives of others.” The use of technology in health care in the United States has increased exponentially over the past 20 years. The most common and most impactful recent technological developments in health care are telehealth, home monitoring, and the electronic health record (EHR).

This section will discuss each of these technologies and how they impact health care costs, the **quality of health care**, and the safety of health care. The Institutes of Medicine define quality as “the degree to which health care services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge” (Agency for Healthcare Research and Quality, 2020). Additionally, health care quality seeks to put into place standard procedures and systems with the intention of having the best possible health outcomes. For example, for a person with diabetes, quality activities would include checking the hemoglobin A1C on a regular basis as well as teaching the person with diabetes about disease self-management. The goal is to control the disease in clients living with diabetes, which also decreases the cost of care. A resulting reduction of the

health care cost is especially advantageous for individuals who are beneficiaries of public health insurance programs such as Medicare and Medicaid.

Telehealth

Telehealth is the use of digital information and communication, including mobile devices such as smartphones, laptop computers, and tablets, to enable remote access to health care services and to facilitate health care management (Mayo Clinic, 2023). With telehealth, a health care provider such as a physician, nurse, or nurse practitioner can provide care to a client in one area while the client is in another. Telehealth has been especially beneficial to individuals living in rural areas, including ethnic minorities who are more likely to live in rural areas and may have limited access to health care services. During the COVID-19 pandemic, when federal and state governments mandated social distancing, telehealth linked health care providers to clients ([Figure 5.5](#)). Some key benefits of telehealth are that it:

- Allows for the remote monitoring of chronic diseases such as diabetes, hypertension, and heart disease
- Allows for remote monitoring of mental health and behavioral health conditions
- Allows for the coordination of care services between two or more health care providers (i.e., primary care provider and specialty care provider)
- Allows for improved communication between the client and the health care provider
- Increases access to health care services for individuals living in rural areas
- Allows for social distancing during pandemics such as COVID-19
- Allows clients to receive care in their home by way of mobile devices such as smartphones and tablets

FIGURE 5.5 Telehealth enables nurses and other health care professionals to communicate with each other and to provide care to clients who may not be able to access a health care facility in person. (credit: Jacob Sippel/U.S. Navy/Flickr, Public Domain)

As of 2020, 76 percent of hospitals in the United States used telehealth to remotely connect with clients, up approximately 35 percent from 2010 (Watson, 2020). Telehealth has gained in popularity in the United States. The need for telehealth became more apparent during the COVID-19 pandemic. A research study found that approximately three-quarters of individuals living in the United States were more eager to participate in virtual health care experiences due to a fear of being infected with the disease secondary to face-to-face interactions between clients and health care providers (Watson, 2020). Although the use of telemedicine has its positive benefits, there are downsides: it cannot be used for every type of visit; its use involves the risk of personal health data being breached; and health insurance companies may not cover each virtual visit type (Watson, 2020). Certain regions of the country—like remote and/or rural areas—may also lack access to the broadband high-speed internet access necessary for telehealth services (RHIH, 2022). According to Call (2022), in 2020 organizations invested

over \$14.1 billion in telehealth and other digital health technologies.

CASE REFLECTION

Addressing Barriers to Access

Read the scenario, and then respond to the questions that follow.

A 40-year-old client presents to the local community health center for treatment of his ongoing type 2 diabetes. Upon assessment, the nurse learns the client is having difficulty affording his medication and must pay his neighbor to drive him 30 miles to his doctor's appointments. The client reports that he was laid off from his job over a year ago and has had an extremely hard time adjusting. The client's blood glucose is 300 fasting. His hemoglobin A1C is 8, and he appears to be extremely anxious.

1. What might the nurse do to address the client's anxiety related to losing his job previously?
 2. Given the client's difficulty in presenting to his doctor's appointments due to transportation, what might be an option for the client?
-

The use of telehealth has ushered in cost savings for clients and health insurance providers, both public and private. A 2017 study found that telehealth appointments cost clients \$79 out of pocket, as opposed to \$146 for an in-person office visit (Ashwood et al., 2017). Telehealth also provides an estimated savings of \$89 billion each year in lost time associated with travel to and from doctor's visits. Additionally, telehealth has lowered costs associated with unnecessary emergency department visits. It is estimated that more than \$1,500 per visit is saved by using telehealth instead of an emergency department (Call, 2022). This is especially significant for ethnic minorities, who are less likely than White individuals to have adequate insurance coverage and are therefore more likely to use the emergency department to receive care (CDC, 2020a). Research has indicated that as many as 90 percent of telehealth clients say they would not have sought care if telehealth was not available to them (Call, 2022); however, access to telehealth may be limited if the individual does not have adequate health insurance.

Although the use of telehealth has shown many benefits, it also presents challenges, including potential fraud and waste, which increase costs (Call, 2022). Examples of fraud and waste include providers coding check-in phone visits as full telehealth visits between the client and the health care provider and billing for services that were not provided. Additionally, the time and effort it takes for health care organizations to deploy the technology of telehealth in their facility increases costs. Organizations are exploring the use of artificial intelligence to combat the increase in costs related to telehealth set-up and deployment (Call, 2022). The use of artificial intelligence has the potential to, in some instances, remove the need to have a human on the opposite side of telehealth as is currently required for the system to work properly (Kuzimesky et al., 2019).

Electronic Health Records

The HHS (2020, para. 1) defines the **electronic health record** (EHR) as "an electronic version of a client's medical history, that is maintained by the provider over time and may include all the key administrative clinical data relevant to that person's care under a particular provider, including demographics, progress notes, problems, medications, vital signs, past medical history, immunizations, laboratory data and radiology reports" (HHS, 2020). Sometimes, an older term, **electronic medical record** (EMR), is used. An EMR is generally associated with software that contains very specific clinical functions—such as checking for drug interactions and allergies—as well as with the documentation of the interaction between the client and the health care provider.

The EHR enables the recording, tracking, and maintenance of the client's information:

- health care record
- problem list
- demographics
- medications
- medical history
- care plans

EHRs are essential to maintaining client safety and quality of care. They provide a means by which the provider can track certain clinical measures associated with the client's health care. EHRs also facilitate communication, providing a mechanism by which providers may convey instructions, guidelines, and protocols to clients after discharge and a means by which health care providers and organizations may communicate with each other (HHS, 2020). Improved communication improves client safety. For example, the EHR helps reduce medication errors, preventing the client from being prescribed the same medication twice or being prescribed a harmful combination of medications (HHS, 2020).

UNFOLDING CASE STUDY

Part B: Demographic Factors

Read the scenario, and then answer the questions that follow based on all the case information provided in the chapter thus far. This case study is a follow-up to Case Study Part A.

The client, Jose, presented with chest pain. Upon further assessment and evaluation, the physician has ruled out a heart attack. Instead, the physician believes Jose is experiencing anxiety. The nurse educates Jose on the diagnosis and works with him to develop a treatment plan. The client appears to be reluctant to share information with the nurse but does reveal that he has been treated for hypertension since the age of 23. Because he recently lost his job, he has been unable to afford health insurance. For this reason, he could not afford his blood pressure medications and has not taken them for the past 6 months. Jose appears tearful and anxious. He answers the nurse's questions with brief responses. Jose and his family have also started utilizing a local food bank and have applied to the Supplemental Nutrition Assistance Program (SNAP). The nurse suspects that Jose is experiencing more financial hardship than he is sharing. The physician has prescribed medication for Jose, but the nurse is concerned he cannot afford to get the prescription filled.

3. What is the best approach the nurse can adopt to increase Jose's trust and facilitate further discussion about his circumstances?
 - a. The nurse should provide the client with a list of financial resources.
 - b. The nurse should acknowledge Jose's concerns and explain what financial resources and other sources of support are available to him.
 - c. The nurse should let the client's family know what he needs.
 - d. The nurse should tell the client that if he can control his anxiety then everything will seem better.
 4. Based on the nurse's experience working with vulnerable populations, which of the following is the best approach for ensuring that Jose takes the new medication as prescribed?
 - a. Explain to Jose and his family the benefits of the new medication.
 - b. Explain to Jose and his family the risks of not taking the new medication.
 - c. Develop a plan for Jose to manage any adverse drug effects.
 - d. Connect Jose with resources so that he can get the medication at minimal to no cost.
-

Home Monitoring

With **home monitoring**, clients use devices such as digitized scales, blood pressure monitoring devices, and glucometers (blood glucose monitor) that are linked to the EMR in the physician's office. Mobile applications through the client's smartphone, smartwatch, and other tracking devices, such as step trackers, are used to collect client data like heart rate and connect it directly to the client's health care provider. According to the Health Resources and Services Administration (HRSA, 2023), home monitoring is often paired with telehealth to allow for the long-term and continuous monitoring of chronic diseases such as high blood pressure, diabetes, obesity, heart disease, chronic obstructive pulmonary disease, sleep apnea, and asthma. The use of home monitoring has led to improved health outcomes associated with these chronic diseases as well as cost savings for the client and the health care facility (HRSA, 2023). Home monitoring impacts both client safety and quality. As it relates to quality, health care providers can monitor health indicators such as blood pressure and hemoglobin A1C while the client is home. When health care providers notice an abnormal lab value, as an example, they can more readily address the issue in many instances without the client having to come to the clinic or hospital. Health outcomes are further improved by

preventing hospital readmissions and emergency department visits, decreasing the cost of care. Client safety is also achieved in this example (HRSA, 2023).

HEALTHY PEOPLE 2030

Health IT

Healthy People 2030 includes the goal of helping health care providers and clients use [health information technology](https://openstax.org/r/healthit) (<https://openstax.org/r/healthit>) to access and exchange health information. Health information technology (health IT) is essential to the sharing of information between the client and their health care provider. The sharing of information allows the client to have access to their health information and enables them to use it more effectively, which can lead to better health outcomes.

(See ODPHP, 2023a.)

5.4 Health Care Workforce

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 5.4.1 Evaluate workforce shortage trends that could jeopardize access to health care.
- 5.4.2 Assess the impact of the COVID-19 pandemic on the health care workforce.
- 5.4.3 Discuss the lack of diversity among the health care workforce and its impact on client care.
- 5.4.4 Discuss the aging of the health care workforce and its impact on the nursing workforce shortage.

According to the American Nurses Association (2023), there are approximately 4.3 million registered nurses working in various settings across the United States. Nurses are key to ensuring positive health outcomes for clients and communities. A strong health care workforce is essential to address health disparities in the United States. However, the American Hospital Association (AHA) found that between 2019 and 2020, health care workforce vacancies increased by 30 percent (AHA, 2023a).

Effects of the COVID-19 Pandemic on the Nursing Workforce

The COVID-19 pandemic precipitated the “great resignation,” during which more than 50 million Americans quit their jobs (Richter, 2023). The great resignation was especially impactful in health care, as many health care providers, including registered nurses, exited the health care system in mass numbers (Balasubramanian, 2022). A study by the Kaiser Family Foundation (2021) found that approximately three in 10 health care workers considered leaving the profession during the COVID-19 pandemic. Approximately six in 10 health care workers stated that stress related to the pandemic impacted their mental health. An additional survey by the American Organization for Nursing Leadership, which falls under the umbrella of the American Heart Association, found that nurses stated that “emotional health and well-being of staff” were the top challenges nurses faced during the COVID-19 pandemic.

Effects of the Registered Nurse Shortage

The American Nurses Association refers to registered nurses as the backbone of the health care system. Without adequate highly qualified registered nurses, client health outcomes will suffer.

The U.S. Bureau of Labor Statistics projects that there will be an average of approximately 194,500 annual openings for registered nurses between 2020 and 2030. By 2026, there will be an estimated shortage of approximately 3.2 million health care workers (AHA, 2023b). A shortage of qualified health care professionals such as registered nurses, physicians, and respiratory therapists, for example, limits access to quality health care services for individuals who already experience less-than-optimal health outcomes. Prevention is one of the top means by which chronic diseases such as diabetes, heart disease, and hypertension can be controlled, especially in underrepresented communities. Individuals from these communities, who disproportionately experience chronic diseases, would benefit from preventive health care services that public health nurses are well qualified to provide.

A U.S. Bureau of Labor Statistics study suggested that more than 275,000 additional nurses would be needed from 2020 to 2030 (Balasubramanian, 2022). Employment opportunities for nurses are projected to grow at a faster rate (9 percent) than all other occupations from 2016 through 2026 (Balasubramanian, 2022).

The nursing shortage is the most significant of any profession in the health care system. For this reason, extra attention and emphasis are being placed on the number of nurses needed for the health care system to function properly. The American Hospital Association framed the nursing shortage as a national emergency and predicted a deficit of 1.1 million nurses by the end of 2022 (AHA, 2023b; Chamlou, 2022). Hospitals in major cities, with their larger populations, have experienced the worst level of nursing staff shortages when compared with other areas and settings throughout the country. Rural areas are also impacted, especially in hospitals in less populous areas (Chamlou, 2022), where access to health care is already lacking. According to the Kaiser Family Foundation, rural hospitals have fewer intensive care unit (ICU) beds: approximately 1.7 per 10,000 people when compared with 2.8 per 10,000 in more populated urban areas. For this reason, rural hospitals tend to become overwhelmed faster than urban care centers. Additionally, nursing salaries tend to be lower in rural areas, which makes it more difficult to recruit nurses in these areas (Chamlou, 2022).

The lack of qualified health care workers has driven up wages, especially for nurses. This increase in wages has placed a financial strain on the health care system, which has led to an increase in health care costs across the board. When hospitals and other organizations within the health care system increase costs, access to care for vulnerable populations may be further hampered, which, as has been stressed throughout this chapter, leads to less-than-optimal health outcomes for these individuals.

One of the issues contributing to the shrinking number of health care providers is the aging of the nursing workforce. According to the American Nurses Association (2023), the median age of registered nurses in 2020 was 52. Approximately one-fifth of these nurses expressed their intent to retire within the next 5 years.

Achieving Diversity in the Nursing Workforce

In addition to the overall shortage of personnel in health care, the health care workforce lacks diversity. Nurses care for clients across the gender spectrum; however, in 2020, 90 percent of all nurses worldwide were female (Buchan & Catton, 2020). A study conducted by the National Council of State Boards of Nursing (NCSBN) asked members of the nursing workforce to self-identify by race/ethnicity. The study found a striking lack of diversity in the workforce, in stark contrast to the diversity of the client populations nurses serve ([Figure 5.6](#)).

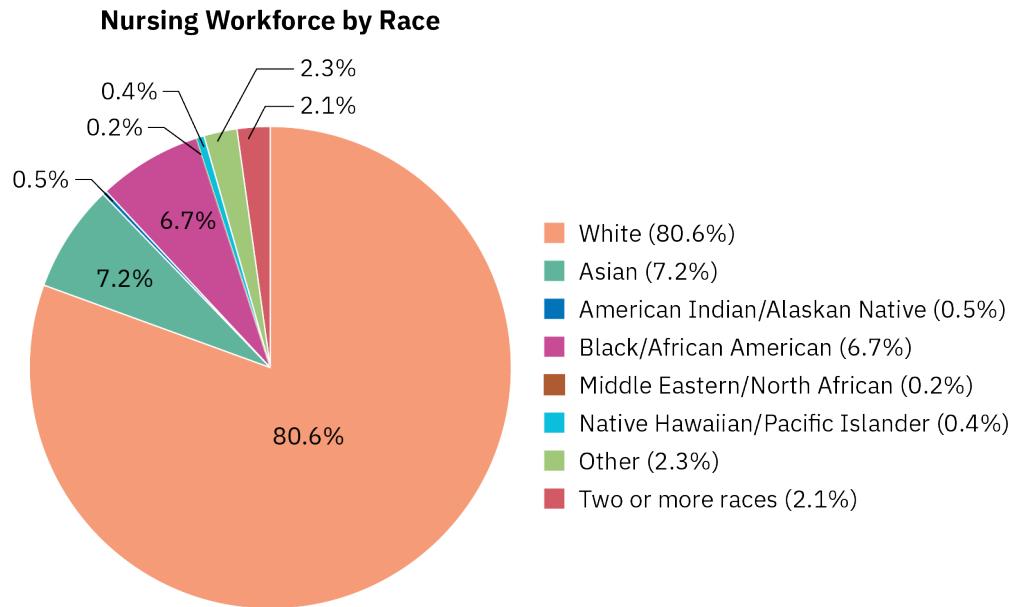

FIGURE 5.6 The nursing workforce in the United States is predominantly White according to the results of the 2020 National Nursing Workforce Survey. (data source: American Association of Colleges of Nursing, 2023; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Given these statistics, the AACN, along with other national organizations such as the National Black Nurses Association, National Coalition of Ethnic Minority Nurse Associations, and the National Association of Hispanic Nurses, asserts that, to address increasing racial and ethnic diversity in the U.S. population, it is necessary to further diversify the nursing workforce (AACN, 2023). Research has shown that racial and ethnic minority health care providers are more likely to return to their communities to provide care, and these providers are more likely to

advocate for those communities. They are able to bridge cultural and linguistic gaps related to client education and the provision of care, which leads to better health outcomes for individuals in those communities (AACN, 2023).

Nursing leaders recognize and understand the link between a nursing workforce that is culturally diverse and that workforce's ability to provide high-quality and culturally appropriate care (AACN, 2023). To provide quality care for other underrepresented populations, such as members of the LGBTQIA+ community and individuals with disabilities, increased representation of those individuals in the nursing workforce is needed.

The current shortage of nurses and the need for more diversity among nursing faculty both threaten already compromised health outcomes for underrepresented groups (AACN, 2023). Organizations such as the AACN have strategies in place to address this issue. For example, the Building a Culture of Belonging in Academic Nursing program, a program funded by Johnson and Johnson in January 2022, seeks to assist nursing schools in creating a more inclusive environment. A more diverse nursing faculty can help ensure a more diverse nursing workforce. According to the AACN (2023), nursing students tend to have better outcomes and are more successful when faculty can relate to them culturally. In addition to the need for minority professionals to practice in their home communities, there is a great need for policies that can ensure positive health outcomes within underrepresented groups (AACN, 2023).

Chapter Summary

5.1 Demographic Factors

The demographic makeup of the U.S. population continues to change, with communities that have concentrations of groups such as older people, minority racial and ethnic groups, and others often underrepresented in the social and political power structure. Such groups tend to experience higher rates and greater severity of chronic disease, lack of access to and a distrust of health care resources, and the inability to afford health insurance. The fastest-growing demographics are baby boomers, racial and ethnic minorities, and vulnerable groups like those living in poverty, sexual and gender minorities, and individuals with disabilities. As these demographic changes continue, the delivery of health care will have to change to ensure health equity and the elimination of health disparities, which currently impact underrepresented populations disproportionately throughout the United States.

5.2 Health Care Consumer Behavior

Factors that affect health care consumer behavior include cost, availability of services and providers, and degrees of consumer confidence in those services and providers. Consumer behavior affects health care costs. For example, populations that tend to neglect health care until chronic diseases and mental health disorders become severe are more costly to treat than preventive care would have been. This also pushes up the price of costly prescriptions needed to treat advanced health conditions. Conversely, the high cost of health care and health care insurance prevents consumers from using health care services. Many consumers turn to emergency department visits because hospitals by law cannot turn away clients. If the client is unable to pay, the hospital bears the cost

Key Terms

chronic disease conditions such as hypertension, diabetes, kidney disease, heart disease, and cancer that individuals live with for a year or more and that require ongoing medical attention, limit the activities of daily living, or both

demographics statistical data relating to particular groups within a population

electronic health record (EHR) electronic version of a client's medical history that is maintained by the provider over time and may include all key administrative clinical data relevant to that person's care under a particular provider (e.g., demographics, progress notes, problems, medications, vital signs,

of care given, thereby further increasing the cost of health care overall. As the face of America continues to change, how individuals as consumers interact with the health care system will increasingly be a factor that must be addressed.

5.3 Virtual Care and Technology

As U.S. demographics change, developing new ways to reach and care for clients is crucial to ensure positive health outcomes. Technologies such as telehealth vastly increase the accessibility of health care providers and services. Telehealth has proven especially effective in improving accessibility to rural areas that often have fewer health care facilities and providers. Additionally, as care of older adults shifts from hospitals and rehab centers to the home, home monitoring, EHRs, and telehealth can enable high-quality, safe, and comfortable homecare for clients. The same is true for the monitoring of chronic diseases such as diabetes, which especially affects minorities and older adults.

5.4 Health Care Workforce

Nurses are the backbone and necessary component of the health care system, which cannot function without them. The current severe shortage of nurses is caused partly by the aging of the nursing workforce (the number of nurses reaching age 65 and retiring) and partly by the COVID-19 pandemic. The significance of the nursing shortage is prompting a great deal of attention on estimating the number of nurses needed for the health care system to function properly and on how to train and recruit new nurses. At the same time, the need for greater diversity in the nursing workforce is gaining increased recognition and attention.

past medical history, immunizations, laboratory data, and radiology reports)

electronic medical record (EMR) software that performs specific clinical functions, such as checking for drug interactions and allergies, and handles documentation of client encounters (i.e., the interaction between the client and the health care provider)

ethnic minorities population groups with a shared culture, tradition, religion, language, history, or other factor who live in communities or areas where most people are from a different ethnic group

health care consumer recipient of health services,

whether those services are paid for or provided at no cost

health disparities preventable differences in the burden of disease, injury, violence, or opportunities to achieve optimal health that are experienced by socially disadvantaged populations

health equity state in which everyone has a fair and just opportunity to attain their highest level of health

home monitoring use of devices such as digitized scales, blood pressure monitoring devices, and glucometers (blood glucose monitor) that are linked to the EHR or EMR in the physician's office

mental health emotional, psychological, and social well-being; affects how an individual thinks, feels, acts, handles stress, relates to others, and makes choices

quality of health care degree to which health care services for individuals and populations increase the

likelihood of desired health outcomes and are consistent with current professional knowledge

stigma shaming attached to an individual's circumstance, background, personal traits, or associations that can lead to discrimination; often the result of ignorance or fear

telehealth use of digital information and communication technologies to access health care services remotely and manage health care

underrepresented populations subgroups within a population—often identified by race, ethnicity, age, sex, gender, sexual orientation, or socioeconomic status—whose representation in society is disproportionately low relative to their numbers

vulnerable populations groups and communities at a higher risk for poor health as a result of the barriers they experience to social, economic, political, and environmental resources, as well as limitations due to illness or disability

Review Questions

1. Which concept should the nurse consider when developing community programs to meet the needs of the baby boomer generation?
 - a. The baby boomer population is steadily declining.
 - b. There is an increase in the need for long-term care.
 - c. The average age of the U.S. population is decreasing.
 - d. The prevalence of chronic disease is declining.

2. A nurse works in a community health center whose population consists of many working poor. Which characteristic would the nurse expect in this population?
 - a. Most clients receiving care in the clinic hold jobs but are uninsured.
 - b. Most clients are working and have health insurance.
 - c. Most clients engage in health-promotion activities since they do not have health insurance.
 - d. Most clients will qualify for Medicaid benefits.

3. Which statement should guide the care a nurse provides to clients in a community health clinic that serves an ethnic minority group?
 - a. Health disparities are preventable differences in health.
 - b. Hypertension affects all ethnic groups equally.
 - c. Underrepresented populations engage in health-promotion activities.
 - d. The population of ethnic minorities in the United States is declining.

4. A client at a rural community health center has been diagnosed with diabetes and has scheduled a telehealth appointment with a diabetes educator. Which client statement about seeing a provider via telehealth indicates to the community health nurse that more teaching is needed?
 - a. "I will get the same level of care as an in-person visit."
 - b. "This will save me a 2-hour drive to the city."
 - c. "Telehealth reduces communication with the diabetes educator."
 - d. "This will allow close monitoring of my diabetes."

5. Which statement best describes the impact of COVID-19 on the nursing profession?
 - a. The pandemic highlighted nursing as a desirable profession.
 - b. Nurses are now more vigilant about the care they provide for clients.

- c. Many nurses left the health care system.
 - d. Nursing salaries have decreased due to the impact of COVID-19 on the finances of health systems.
6. A nurse is working in a community health clinic that serves a large Asian population. Which health factor should the nurse consider when providing care to this population?
- a. There is a higher rate of hepatitis B than in other ethnic groups.
 - b. The rate of tuberculosis is lower than all people diagnosed with this infection.
 - c. They are more likely to receive care for mental health issues.
 - d. There is a lower genetic risk for developing prediabetes.
7. A 38-year-old client, who identifies as transgender, presents to a community health center with symptoms of an upper respiratory infection. During the intake assessment, the client tells the nurse that they do not receive regular health care and do not have a primary health care provider. As the nurse performs an assessment of this individual, which finding does the nurse anticipate?
- a. An absence of preventable diseases
 - b. A distrust of the health care system
 - c. Positive past health care encounters
 - d. Up-to-date cancer screenings
8. Which intervention should the nurse use to instill trust in underrepresented clients in a community health center?
- a. Asking family members to remain in the waiting area
 - b. Assessing the client's potential barriers to care
 - c. Providing education materials in English
 - d. Learning about the client's culture by reading about it
9. Which statement should guide the nurse in helping an underrepresented client obtain health insurance based on the ACA?
- a. The age of qualification for Medicare was lowered.
 - b. Medicaid financial eligibility requirements were lowered.
 - c. Administration of Medicaid was transferred to the federal government.
 - d. Individuals with disabilities are no longer covered by Medicare.
10. The nurse is recommending that a client in a rural area monitor their blood pressure electronically at home to determine the effectiveness of antihypertensive medication and lifestyle changes and to follow up using telehealth. Which information will the nurse provide the client about telehealth visits?
- a. There is no charge for telehealth visits.
 - b. It allows the nurse to see trends in the client's blood pressure.
 - c. It increases the number of emergency department visits.
 - d. It is not as effective in treating conditions as in-office visits.

CHAPTER 6

Structural Racism and Systemic Inequities

FIGURE 6.1 In 2020, throughout the United States, hundreds of Black Lives Matter protests signaled a renewed focus on racial justice and a recognition that structural racism exists in the United States. (credit: modification of work "Black Lives Matter" by John Lucia/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 6.1 Understanding Different Forms of Racism
 - 6.2 The Historical Context of Structural Racism in the United States
 - 6.3 Contemporary Structural Racism and Systemic Inequities in the United States
 - 6.4 Structural Racism and Systemic Inequities in U.S. Health Care
-

INTRODUCTION For decades, U.S. agencies including the U.S. Census Bureau, the National Center for Health Statistics, the Agency for Healthcare Quality and Research, the National Center for Educational Statistics, and the Bureau of Labor Statistics have documented racial and ethnic inequalities in the United States in health, in the criminal justice system, in the education system, and in socioeconomic status (Bailey et al., 2017). The following are just a few examples of the many racial inequalities in the United States.

- Significant differences in mortality rates from heart disease, breast cancer, and stroke exist between Black and White Americans, with Black Americans dying at much higher rates (Hostetter & Klein, 2018).
- A Black woman is 22 percent more likely to die from heart disease than a White woman, 71 percent more likely to die from cervical cancer, and 243 percent more likely to die from pregnancy and childbirth-related causes (Hostetter & Klein, 2018).
- Though drug use is a major public health threat affecting all races, Black Americans are imprisoned for drug crimes at six times the rate of White Americans. Nearly 80 percent of individuals in federal prison for drug offenses are Black or Latino/Latina (Pearl, 2018).
- One in three Black men can expect to go to prison in their lifetime (American Civil Liberties Union [ACLU],

2023).

- In 2018, Black students were four times as likely as White students to be given an out-of-school suspension despite representing only 15 percent of the total enrollment in public schools (Churchwell et al., 2020).
- On average, Black families in the United States have one-twentieth the wealth of White families (Beech et al., 2021).

This chapter will explore the reasons behind these disparities. A history of patterns and practices have reinforced discriminatory beliefs and distribution of resources, resulting in structural racism and systemic inequities.

Discrimination refers to unfair treatment of individuals and groups based on certain characteristics such as race, ethnicity, gender, age, religion, sexual orientation, and ability (Office of Disease Prevention and Health Promotion [ODPHP], 2020a). Distribution of resources relates to the social determinants of health (SDOH), or the social factors that significantly impact health outcomes. Access to safe housing, quality education, and income level are SDOH that are founded on inequitable distribution of resources due to historical and contemporary racism. To improve population health and achieve **health equity**, a condition in which everyone has a fair opportunity to attain their highest level of health, nurses and health care professionals must understand the impact of structural racism and work to dismantle these longstanding discriminatory behaviors.

6.1 Understanding Different Forms of Racism

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 6.1.1 Define racism and its associated levels.
- 6.1.2 Discuss ways in which forms of racism affect health care.

Racism is a type of bias that assigns value and determines opportunity based on people's appearance or the color of their skin, resulting in conditions that unfairly advantage some individuals while disadvantaging others (Centers for Disease Control and Prevention [CDC], 2023). Race is a social construct, a way of categorizing or dividing individuals based on physical traits, social factors, and cultural backgrounds; it is not biologically based (Baker, 2021; Devakumar et al., 2022; National Institutes of Health [NIH], 2023). There is little genetic variation or difference between racial categorizations (American Medical Association [AMA], 2020; Braveman & Dominguez, 2021; Yudell et al., 2016). Racial categorizations change depending on time period, location, and context, but they are often used to establish a social hierarchy (NIH, 2023). With racism, opportunity is structured, and value is assigned based on the social interpretation of how an individual looks based on their physical traits (National Academies of Science, Engineering, and Medicine [NASEM], 2020). This inequitable process of racial categorization unjustly disadvantages some individuals and communities and is advantageous to others.

Within health care, race-associated differences in health outcomes are documented but not explored or explained, leading many to believe that race is biological even though it is not (Baker, 2021). An example is hypertension. Many students learn that hypertension is more common in Black clients, and these students internalize the belief that being Black is a risk factor for hypertension. However, this assumption does not account for the client's lived experience; the higher risk for hypertension is not due to the client's race but is due instead to *social factors* related to their race (Ackerman-Barger et al., 2020). Leading health agencies such as the Centers for Disease Control and Prevention (CDC), the American Academy of Pediatrics, the American Heart Association (AHA), the American Academy of Family Physicians (AAFP), the National Academy of Medicine (NAM), and the American Medical Association (AMA) now recognize differences in race-associated health outcomes as an outcome of racism (AAFP, 2020; CDC, 2023; Javed et al., 2022; NAM, n.d.; O'Reilly, 2020).

Racism is often described as operating on three levels: structural, personally mediated, and internalized (Jones, 2000).

WHAT IS RACE? WHAT IS ETHNICITY?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-1-understanding-different-forms-of-racism>\)](https://openstax.org/books/population-health/pages/6-1-understanding-different-forms-of-racism)

Though the terms *race* and *ethnicity* are often used interchangeably, they are not the same. Race is externally imposed, a social construct based on certain physical characteristics such as hair color, common ancestry, and

cultural attributes, whereas ethnicity is a self-defined group based on shared kinship, history, and culture.

Watch the video, and then respond to the following questions.

1. What race do you associate with, and why?
2. Why do you think the terms *race* and *ethnicity* are often used interchangeably?
3. Did anything in this video make you feel uncomfortable? If so, why?

Structural Racism

Structural racism, also called institutional racism, is a process resulting in a gap in access to societal opportunities based on race. It is embedded in long-standing policies and is structural in nature, as it is entrenched in every part of society (Bailey et al., 2021; Braveman et al., 2022; Jones, 2000). It is often difficult to recognize because it is so deeply embedded in society through historical practices. Structural racism results in institutional policies, systems, laws, and practices that limit opportunities, resources, and power (Braveman et al., 2022). These deeply rooted practices and beliefs propagate pervasive unjust treatment and oppression of Black people, Indigenous people, and people of color (BIPOC) (Braveman et al., 2022). This includes differential access to quality education, housing, employment, and medical care. It also includes limited power and voice, such as representation within government and the media (Jones, 2000). Due to persistent structural factors that perpetuate past inequalities and biases, an individual's race is frequently an indicator of their socioeconomic status (Jones, 2000). The AMA "recognizes that racism in its systemic, structural, institutional, and interpersonal forms is an urgent threat to public health, the advancement of health equity, and a barrier to excellence in the delivery of medical care" (AMA, 2021, para 4).

Health insurance inequities are a visible modern example of structural racism in health care. Inadequate health insurance is a barrier to accessing quality health care, and the unequal distribution of health insurance coverage contributes to health disparities. In 2019, almost 60 percent of Americans were covered by employer-sponsored health plans: 66 percent of White workers compared with 47 percent of Black workers. Individuals without employer-sponsored health insurance are often uninsured, disproportionately affecting BIPOC communities (Yearby et al., 2022). There are many reasons for this large gap in health insurance coverage, but three of the driving forces behind this disparity are government support for occupational segregation, the National Labor Relations Act of 1935, and the introduction of Medicare and Medicaid (Yearby et al., 2022; Zhavoronkova et al., 2022). [Structural Racism and Systemic Inequities in U.S. Health Care](#) will discuss these forces in greater depth.

Personally Mediated Racism

Personally mediated racism is more commonly known as prejudice and discrimination, in which individuals or communities make assumptions about other individuals or communities based solely on race (NASEM, 2020). Prejudiced individuals act based on their assumptions (NASEM, 2020). Examples of prejudice include police profiling, disrespectful encounters in health care, and teachers devaluing students based on race (NASEM, 2020). Whether personally mediated racism is intentional or unintentional, it maintains structural barriers to equitable treatment (Jones, 2000). Intentional racism is overt and explicit, whereas unintentional racism is more commonly referred to as a form of implicit bias. Implicit biases are unconscious attitudes, beliefs, and associations that result in a negative evaluation of a person based on race, ethnicity, age, gender, or other characteristics (Sabin, 2022). They are called implicit as they are unconscious, have been shaped by prior experiences, and are based on learned associations between certain qualities and social categories. These internal and individual biases exist within the larger social and cultural context of the community that perpetuates biased policies and practices to propagate and maintain systemic and structural racism (Sabin, 2022).

Internalized Racism

Internalized racism refers to members of a stigmatized race accepting negative messages about their abilities and overall worth with self-devaluation, resignation, and hopelessness (David et al., 2019; Jones, 2000; Roberson & Pieterse, 2021). It can be viewed as a result of structural racism as it is based in the setting of whiteness as the norm. It is a process that occurs internally in some individuals experiencing racism whereby they view their own culture with self-doubt and disrespect (David et al., 2019; Roberson & Pieterse, 2021). This results in members of a stigmatized race devaluing their race and sometimes even trying to alter their skin tone, further reinforcing stratification by skin color (Jones, 2000). Internalized racism mirrors the systems of privilege in place, reflecting

societal values and further perpetuating racism (David et al., 2019; Jones, 2000). Studies have indicated that individuals who are more frequently discriminated against based on race experience greater levels of internalized racism (David et al., 2019). In health care, internalized racism could manifest in a variety of ways from psychological distress in clients who are BIPOC to clients who exhibit self-loathing or denouncing one's culture (Rodriguez-Knutsen, 2023; Willis et al., 2021). Clients who experience internalized racism may also demonstrate subservient behaviors to the health care team to fit in and behave in a more mainstream manner (Hagan, 2021).

Scientific Racism: Structural Racism and Unequal Medical Care

Elements of modern American medicine are rooted in scientific racism and eugenics. **Eugenics** is the erroneous theory, linked to historical and contemporary forms of discrimination, racism, ableism, and colonialism, that humans can be improved through the selective breeding of populations (NIH, 2022). Nazi Germany applied eugenics theory leading up to and during World War II and the Holocaust, but eugenics theory has been applied in the United States, too. The U.S. Indian Health Service forced the sterilization of Native American women in the 1960s–1970s (Churchwell et al., 2020), and in the 20th century, the United States used eugenics-based laws in 30 states to involuntarily sterilize at least 60,000 individuals thought to be unfit, feeble-minded, or anti-social (NIH, 2022). These forced sterilizations disproportionately targeted BIPOC individuals, poor White individuals, and individuals with disabilities (NIH, 2022).

Scientific racism, a belief that White Europeans are superior to non-White people, has its origins in the 18th century and was used as a justification for slavery (NIH, 2022). Medical doctors have historically considered Black individuals as inherently diseased and “less than” their White counterparts. Throughout history, Black Americans have been subjected to medical experimentation and forced medical procedures (Bailey et al., 2021). In the 18th century, White physicians inoculated enslaved Black individuals with smallpox to see its effects. In the 19th century, White physicians used enslaved Black individuals as subjects of experimentation for various surgeries, from eye surgeries to gynecologic procedures, without anesthesia. For example, J. Marion Sims, often called the father of modern gynecology, practiced his technique for repairing vesicovaginal fistulas on enslaved Black women without using anesthesia (Bailey et al., 2021). In the infamous Tuskegee Syphilis Study, beginning in 1932, the U.S. Public Health Service experimented on impoverished Black American sharecroppers in Alabama, misleading them about the true nature of the study, not informing them of their syphilis diagnosis, and denying them treatment for the disease (Baker, 2021). The Tuskegee study did not officially end until 1972 despite the existence of a widely available cure for syphilis by 1943 (CDC, 2022c). Scientific racism, contemporary racism, and the historical injustices Black clients experienced within the health care system are factors in this populations' distrust of the medical system (Bajaj & Stanford, 2021). Americans' trust in health care has declined in general, but it is the lowest among Black Americans, with a 2020 poll finding that 55 percent of Black Americans distrust the health care system (Hostetter & Klein, 2021).

INSURANCE GAPS AND MEDICAL DESERTS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-1-understanding-different-forms-of-racism>\)](https://openstax.org/books/population-health/pages/6-1-understanding-different-forms-of-racism)

This Wall Street Journal video highlights the struggles that low-income individuals in rural areas face when trying to access health insurance or health care. Many of these individuals are underinsured or uninsured and struggle with medical costs, ultimately causing them to forgo necessary medical treatment. This burdens the health care system and local hospitals, which end up closing or scaling back the care offered, often putting clients at risk. For example, clients who do not seek treatment for chronic medical conditions such as diabetes or hypertension will experience adverse effects and may end up in the emergency department for acute medical conditions such as kidney failure, blindness, or extremity amputation in the case of untreated diabetes or stroke in the case of untreated hypertension. These acute medical conditions ultimately cost the health care system more as they are largely preventable with appropriate chronic disease management. Insurance gaps and medical deserts negatively impact both clients and those caregivers who treat conditions that likely could have been prevented with appropriate primary care access.

Watch the video, and then respond to the following questions.

1. How does health insurance coverage connect with access to care?
2. Do you feel the government has a responsibility to ensure access to health care for its citizens? Why or why not?
3. How would you explain the intersection between poverty and health outcomes?

In 2003, the Institute of Medicine report [*Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care*](https://openstax.org/r/nap) (<https://openstax.org/r/nap>) reviewed over 100 studies and concluded that bias, prejudice, and stereotyping contribute to disparities in health care by race and ethnicity. Fifteen years later, the [*2018 National Healthcare Quality and Disparities Report*](https://openstax.org/r/nhqdr18) (<https://openstax.org/r/nhqdr18>) documented that Black, American Indian and Alaska Native, and Native Hawaiian and Pacific Islander clients continued to receive poorer care than White clients on 40 percent of quality measures, indicating little or no improvement from prior decades (Bailey et al., 2021). Persistent racist beliefs are partly responsible for these health care disparities. Many studies have demonstrated that health professional students have implicit biases against BIPOC clients, while other studies have found that some medical students still believe there are intrinsic biologic differences between Black and White individuals (Bailey et al., 2021; Fitzgerald & Hurst, 2017; Greenwald et al., 2022; Hall et al., 2015; Hoffman et al., 2016). Overt and implicit biases are not the only causes of unequal medical care between Black and White clients. Structural factors have led to health facilities that lack adequate resources and clinicians. This, in turn, affects client access and utilization (Bailey et al., 2021).

HEALTHY PEOPLE 2030

Health Care Access and Quality

A leading health indicator for Healthy People 2030 is to increase the proportion of people with health insurance. As discussed previously, [*inadequate health insurance is a barrier to accessing quality health care*](https://openstax.org/r/access) (<https://openstax.org/r/access>), and the unequal distribution of health insurance coverage contributes to health disparities. A lack of health insurance coverage disproportionately affects BIPOC communities and is a focus of the Healthy People 2030 goal of promoting health equity and reducing health disparities.

6.2 The Historical Context of Structural Racism in the United States

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 6.2.1 Discuss patterns of structural racism in the history of the United States.
- 6.2.2 Explain how policies of racial apartheid in the United States have reinforced structural racism and systemic inequities.

It is difficult to discuss structural racism without first discussing the long history of racism in the United States. Racism in the United States dates back to British Colonial America, prior to the country's founding, with the ill treatment and forced removal of Native Americans from their lands and the terrible history of slavery. This longstanding history of racism is the foundation of contemporary structural racism.

The Killing and Forced Removal of Native Americans

Native American people have been targets of violence since the first European explorers arrived in North America in the 15th century. The expansion of European settlers and later U.S. government policies resulted in the killing and mistreatment of Native American people (Braverman et al., 2022; Fixico, 2021; Library of Congress [LOC], n.d.-b). From the time of its establishment up to the late 19th century, the U.S. government authorized over 1,500 wars and attacks on Native Americans (Fixico, 2021). For decades, U.S. policies threatened Native American land and autonomy. In 1786, the United States established the first Native American reservation and designated each tribe as an independent nation. In the 1830s, under President Andrew Jackson, Congress passed [*The Indian Removal Act*](https://openstax.org/r/guides) (<https://openstax.org/r/guides>), requiring Native Americans to leave the East and settle in the Indian Territory west of the Mississippi River (Fixico, 2021). Imposing this act, federal soldiers and volunteers forcibly relocated the Cherokee tribe, requiring them to walk 1,000 miles to the Indian Territory with few provisions to sustain them. An estimated 4,000 Cherokee people died on this infamous "Trail of Tears" (Pauls, 2023). Though an estimated 5 to 15

million Native Americans were living in North America when Columbus first arrived in 1492, by the late 1890s, fewer than 238,000 Indigenous people remained in the country (Fixico, 2021). Legally, Native Americans were not citizens of the United States until President Calvin Coolidge signed [The Indian Citizenship Act of 1924 \(<https://openstax.org/r/loc>\)](https://openstax.org/r/loc) (National Constitution Center, 2023b). This status as non-citizens meant the Indigenous population did not have the same legal rights as many other Americans, including the right to vote (LOC, n.d.c).

Slavery and Post–Civil War Reconstruction

In 1619, 20 enslaved Africans were brought to the British colonies in Virginia against their will, likely the first slaves to arrive in what would later become the United States (Shah & Adolphe, 2019). In 1776, when the Declaration of Independence was signed, the lines about all men being created equal did not apply to enslaved people as many of the nation's founders were slaveholders. Slavery flourished on tobacco, cotton, indigo, and rice farms. According to the first U.S. census, 697,624 enslaved people were living in the United States by 1790 (Hacker, 2020, p. 840). By 1808, Congress had banned the slave trade, but slavery was still legal, and by 1860, four million enslaved Black people resided in the United States, representing 13 percent of the population (Shah & Adolphe, 2019). This tremendous growth in the number of enslaved people between 1790 and 1860 was the result of increasing numbers of new slaves being imported from Africa and the Caribbean and due to population growth among the American-born slaves (Hacker, 2020). In 1864, during the Civil War, President Lincoln issued the Emancipation Proclamation, declaring freedom for and protection of enslaved people who lived within the Confederate states that were rebelling against the Union, yet this presidential order did not officially end slavery.

It was not until the ratification of the 13th Amendment on December 6, 1865, 8 months after the end of the Civil War, that slavery was officially abolished in the United States. At this time, Congress implemented Reconstruction efforts to restructure the southern states and to outline the process for White and Black individuals to live together in a post-slavery society (LOC, n.d-a). Opposition to Reconstruction laid the foundation for segregated institutions separated by race (Shah & Adolphe, 2019). The 14th Amendment, passed in 1868, afforded equal protection of the law to all citizens, and the 15th Amendment, passed in 1870, guaranteed that the right of citizens to vote could not be denied on account of race. This trio of Civil War amendments greatly expanded the civil rights of most Americans, but by the late 1870s, Reconstruction efforts came to an end. With the end of Reconstruction, local governments in many of the former Confederate states began building legal systems that undermined the three amendments to codify White supremacy after Reconstruction.

The Jim Crow Era and Systemic Racial Discrimination

The **Jim Crow era** refers to the period from the 1870s through most of the 1960s during which primarily southern U.S. states enacted many discriminatory laws in response to the civil rights and social gains of newly freed Black Americans during the Reconstruction period (Bailey et al., 2017; Shah & Adolphe, 2019). Although they are often thought of as the beginning of the Jim Crow era, the passage of the Black Codes in Mississippi and South Carolina in 1865 and the formation of the White supremacist group the Ku Klux Klan in Tennessee in 1866 were the era's immediate precursors (National Constitution Center, 2023a; PBS, 2023). The Black Codes, often referred to as "slavery by another name," were laws targeted at Black Americans that denied them rights to testify against White individuals, to serve on juries, and to vote and that limited their employment opportunities and the ability to leave a job once hired, often forcing them to work in the fields or as servants, stripping away their autonomy and ability to earn decent wages (History.com editors, 2023; National Geographic, n.d.; PBS, 2021). Founded by six former Confederate officers, the Ku Klux Klan terrorized Black families and pro-reform individuals, especially in rural areas. The Black Codes and Ku Klux Klan are emblematic of the efforts of former Confederate southern states in the post-Reconstruction era to keep Black Americans from gaining money, power, education, or land, all in service of maintaining White dominance (PBS, 2023).

THE BLACK CODES: RECONSTRUCTION

Visit [the PBS LearningMedia website \(<https://openstax.org/r/wisconsin>\)](https://openstax.org/r/wisconsin) to view the video "Black Codes: Reconstruction," which describes the origins and effects of the Black Codes, a set of laws intended to restrict the freedom of Black individuals and compel them to work for White employers in a situation not unlike slavery.

Watch the video, and then respond to the following questions.

1. What legacy do you feel the Black Codes have left behind?
2. What parallels do you see between the institution of the Black Codes and the current treatment of individuals who are experiencing homelessness?

The Jim Crow laws of the 1870s–1880s were a formal system of laws codifying racial segregation and discrimination that dominated the American South, affecting every aspect of daily life. These laws mandated segregated, or separate parks, libraries, restrooms, buses, and trains (PBS, n.d.). This system of segregation prohibited Black Americans from eating at the same restaurants, drinking from the same water fountains, or attending the same schools as White Americans ([Figure 6.2](#)).

FIGURE 6.2 The roots of structural discrimination are evident in this historical photo highlighting Jim Crow Laws. (credit: "At the bus station in Durham, North Carolina" by Jack Delano/Library of Congress, Prints & Photographs Division, FSA/OWI Collection, No known restrictions)

"Separate but Equal" and Civil Rights Laws in the United States

In 1896, the Supreme Court ruled in *Plessy v. Ferguson* that racially separate facilities did not violate the Constitution if they were equal, establishing the “separate but equal” rule (NMAH, n.d.). Though the Supreme Court insisted in *Plessy v. Ferguson* that separate facilities could be equal, the Black American experience of the era suggested otherwise. By the 1900s, Jim Crow laws had created a segregated society condemning Black Americans to unequal treatment and second-class citizenship (National Museum of American History [NMAH], n.d.; Shah & Adolphe, 2019). During the Jim Crow era, many places in the United States prevented Black Americans from exercising the right to vote using a variety of legal maneuvers including literacy tests, poll taxes, complex registration systems, and primaries in which only White people were allowed to vote. It was not until the Supreme Court’s ruling in *Brown v. Board of Education* in 1954 that racial segregation in public schools became illegal. This ruling overturned the “separate but equal” principle and made it unconstitutional for children to be separated in public schools on the basis of race (National Archives, 2021). Despite the *Brown* ruling, Jim Crow laws separating Black Americans from White Americans in housing, jobs, schools, and public gathering places persisted well into the 1960s in many areas of the United States (Shah & Adolphe, 2019).

The Civil Rights Act of 1964 prohibited discrimination based on race and outlawed segregation in businesses, public places, and public schools (National Archives, 2022). The Act made it illegal to discriminate on the basis of race. However, the enforcement of such laws was not and has not been adequate, allowing for the perpetuation of racial inequities and, by extension, socioeconomic inequities. These racial inequities persist due to the unjust systems that have sustained discriminatory practice in policies and laws (Bailey et al., 2017). BIPOC individuals are still significantly disadvantaged in contemporary society due to prior discriminatory laws mandating segregation by race (Braverman et al., 2022). These structures maintaining racial oppression are hidden, ensconced in the normal everyday operations of institutions, and invisible to most except those affected by them (Braverman et al., 2022).

Japanese Internment Camps

The attitudes of racial discrimination common in the Jim Crow era extended to Japanese American individuals living in the United States, who, whether they were citizens and whether they were born in Japan or in the United States, were presumed to be loyal to Japan during World War II. Their loyalties to the United States were questioned solely on the basis of their ancestry. During the war, the United States forcibly detained Japanese Americans in concentration camps, also known as internment camps (Figure 6.3) (National Archives, n.d.). Around 120,000 Japanese-Americans were detained in these camps, imprisoned based on their race, with many losing their homes and businesses (National Archives, n.d.). Most of those interned were U.S. citizens, and half were children, incarcerated for up to 4 years without any recourse. At the time, the U.S. Supreme Court accepted the implementation of President Roosevelt's Executive Order 9066, determining that civil rights could be denied to U.S. citizens based on the executive branch's definition of membership in a specified ethnic group.

FIGURE 6.3 Japanese Americans arrive at Santa Anita Assembly Center in California in 1942 during the first phase of relocation and internment. (credit: Clem Albers/National Archives, Public Domain)

Boarding School Policy for Native American and Alaska Native Children

From 1869 through the 1970s, the U.S. government forcibly removed Native American and Alaska Native children as young as age 4 from their families, homes, and cultural traditions, placing them into boarding schools with the goal of replacing their tribal values, languages, and culture with dominant White Christian values, religion, culture, and language (Braveman et al., 2022; National Native American Boarding School Healing Coalition [NNABSHC], 2020). This practice began with the Civilization Fund Act of 1819, which financed Christian churches to provide education that fostered “civilization” for Native Americans (LoneTree, 2021; Wong, 2019). In 1824, the Bureau of Indian Affairs assumed oversight of the program, which ultimately became a program of cultural genocide (NNABSHC, 2020). Children in the program faced harsh punishment if they spoke their native language or engaged in Native American cultural practices. Survivors of the schools recount sexual, physical, and spiritual abuse; neglect; and witnessing murders of other children. By 1925, the Bureau of Indian Affairs had placed over 60,000 children—approaching an estimated 83 percent of all Native American children in 1926. Overall, the United States funded 367 Native American boarding schools operating in 29 states.

Over time, the poor conditions in these schools did not go unnoticed. For example, the 1928 *Meriam Report: The Problem of Indian Administration* (<https://openstax.org/r/narf>) documents starvation, poor and unsanitary living conditions, and the harmful effects of corporal punishment on children’s mental health at these boarding schools (NNABSHC, 2020). However, it was not until passage of the 1975 Indian Self-Determination and Education Assistance Act that Native Americans gained legal control of their own educational systems (Avalos, 2021), and the passage of the 1978 Indian Child Welfare Act protected Native children from forced adoption or placement in foster

care with non-Native individuals (Braveman et al., 2022; NNABSHC, 2020). The effects of these forced removals have resulted in significant cultural losses for tribal nations.

Redlining and Residential Segregation by Race

During the 1930s, the U.S. government sanctioned **residential racial segregation** via the Home Owners' Loan Corporation (HOLC) and the Federal Housing Administration (FHA). Residential racial segregation is the practice of keeping racial communities separate based on where people live. The HOLC was established in 1933 as part of the New Deal programs to relieve the effects of the Great Depression, to assist homeowners who defaulted on their mortgages and were in foreclosure, and to expand homeownership for the average middle-class American family.

HOUSING SEGREGATION AND REDLINING IN AMERICA: A SHORT HISTORY

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-2-the-historical-context-of-structural-racism-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-2-the-historical-context-of-structural-racism-in-the-united-states)

This NPR podcast video explores the history of redlining with an emphasis on its legality. Despite the passage of the Fair Housing Act, maps and census data show that housing segregation persists.

Watch the video, and then respond to the following questions.

1. Are you surprised by the history of legalized discrimination in housing and banking practices? Why or why not?
2. How do residential segregation and racial profiling intersect?

As a part of its City Survey Program, the HOLC employed examiners who consulted with local bank officers, city officials, appraisers, and realtors across the country to appraise neighborhoods according to perceived lending risk. Using this information, the HOLC created Residential Security maps of cities that graded neighborhoods based on condition and age of housing, transportation, proximity to parks and polluting industries, and the economic class and ethnic and racial composition of the residents (Mitchell & Franco, 2018). Examiners assigned each neighborhood a letter grade and then outlined them on the map in different colors. Green neighborhoods received the letter A, indicating the best neighborhoods; blue neighborhoods received the letter B, indicating desirable neighborhoods; yellow neighborhoods received the letter C, indicating neighborhoods in decline; and red neighborhoods received the letter D, indicating “hazardous” or high-risk (Mitchell & Franco, 2018). Loan officers, appraisers, and real estate professionals used these maps to calculate or estimate mortgage lending risk in the 1940s and 1950s (Mitchell & Franco, 2018).

Red lines were often drawn around communities that had predominantly Black populations, effectively labeling them as risky investment areas (Figure 6.4) (Bailey et al., 2021). **Redlining** these communities of color made mortgages on homes in these areas less available, placing Black homebuyers at risk for predatory lending terms and reducing their access to home ownership. The term *redlining* came to mean a system of denying borrowers access to mortgage loans based on the location of properties in disadvantaged neighborhoods that were often made up of minority populations (Mitchell & Franco, 2018). Borrowers who obtained loans in HOLC red zones paid higher interest rates. Some White homeowners signed **restrictive racial covenants** that prevented them from selling their homes to non-White individuals. These covenants were justified as protecting the value of the home and other neighborhood properties, and they allowed brokers to follow segregation standards in the resale of properties acquired by foreclosure (Mitchell & Franco, 2018). Restrictive racial covenants became popular in the immediate post–World War II era and were often required by the FHA for builders or homeowners to receive homeowners’ insurance. This further undervalued real estate in BIPOC neighborhoods and incited violence against BIPOC individuals who moved into White neighborhoods (Bailey et al., 2021).

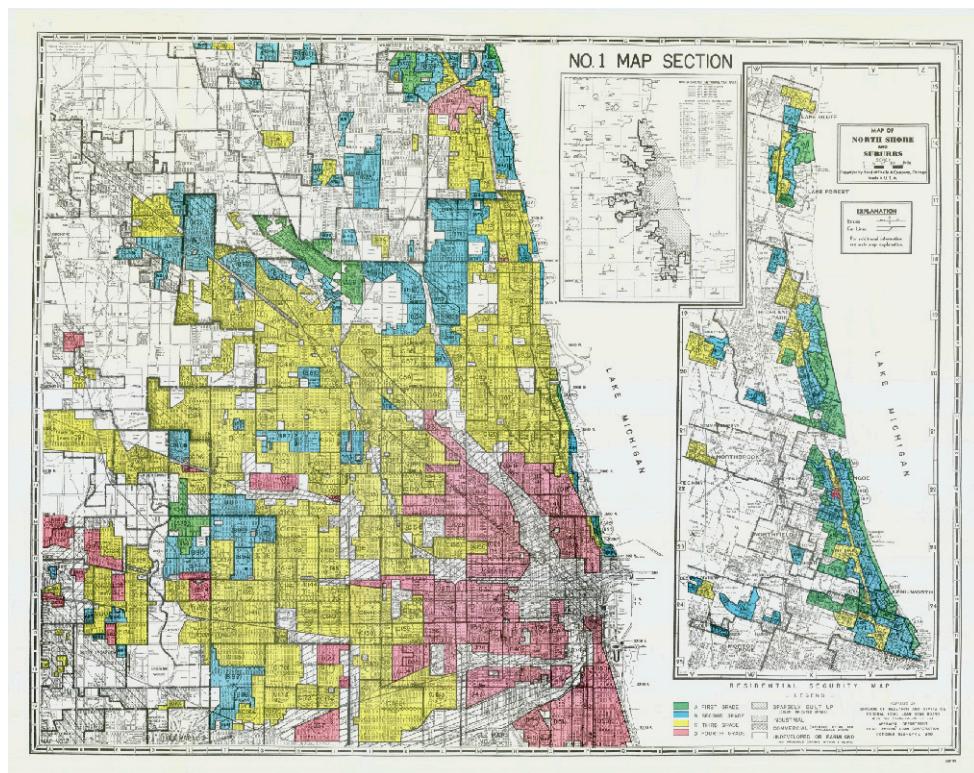

FIGURE 6.4 In this HOLC-era redlined map of Chicago, red areas outline so-called “hazardous” urban, industrial neighborhoods that house a majority-BIPOC population, whereas the green areas outline neighborhoods in suburbia, away from the inner city and associated industrial pollution. (credit: “holc-chicago” by Kara Zelasko/Flickr, Public Domain)

Multiple sectors, including banking, real estate, private developers, and homeowners, were involved in redlining and restrictive racial covenants, all with the cooperation and backing of the U.S. government. Lending was discouraged in red zones, while green neighborhoods were preferred (Mitchell & Franco, 2017). The FHA refused to insure mortgages in or near redlined communities while subsidizing builders who produced subdivisions in suburbia for White Americans (Gross, 2017). As a condition for these subsidies, the FHA required restrictive racial covenants to prevent BIPOC individuals from purchasing homes in these subdivisions, justifying their policy to ensure their loans would not be at risk (Gross, 2017). That the FHA included these covenants in its Underwriting Manual amounts to a U.S. government agency essentially stating in an official document that different racial groups should not live in the same communities (Gross, 2017). These practices perpetuated stereotypes that Black individuals would be poor neighbors, would drive down home values, and would increase crime (Bailey et al., 2021).

As a result of these policies, White Americans in the 1950s began leaving urban areas for the suburbs, a phenomenon often referred to as **white flight**, largely blocking BIPOC individuals from new suburban housing communities and isolating them in urban housing projects (Filippino, 2017; Gross, 2017).

Another government action that segregated BIPOC communities during the late 1950s through the early 1970s was the 1956 Federal-Aid Highway Act. This law authorized the largest public works program in history at that time, promising to construct 41,000 miles of an interstate highway system crossing the nation and connecting 42 state capitals. A consequence of this highway expansion was the displacement of more than one million people, largely in urban BIPOC communities (Evans, 2021). Highways cut through neighborhoods, disrupted green spaces, worsened air quality, and sank property values (Figure 6.5). Communities already struggling due to disinvestment and white flight ended up losing churches, community spaces, homes, and small businesses (Evans, 2021). Policymakers viewed highway construction as an easy way to destroy undesirable neighborhoods and used concrete walls, ramps, and overpasses as further physical tools of segregation to isolate BIPOC communities (Evans, 2021). These highways were built during the civil rights movement, and as the prospect of integrated neighborhoods became more real, highway construction offered a means to reinforce racially segregated neighborhood boundaries (Evans, 2021).

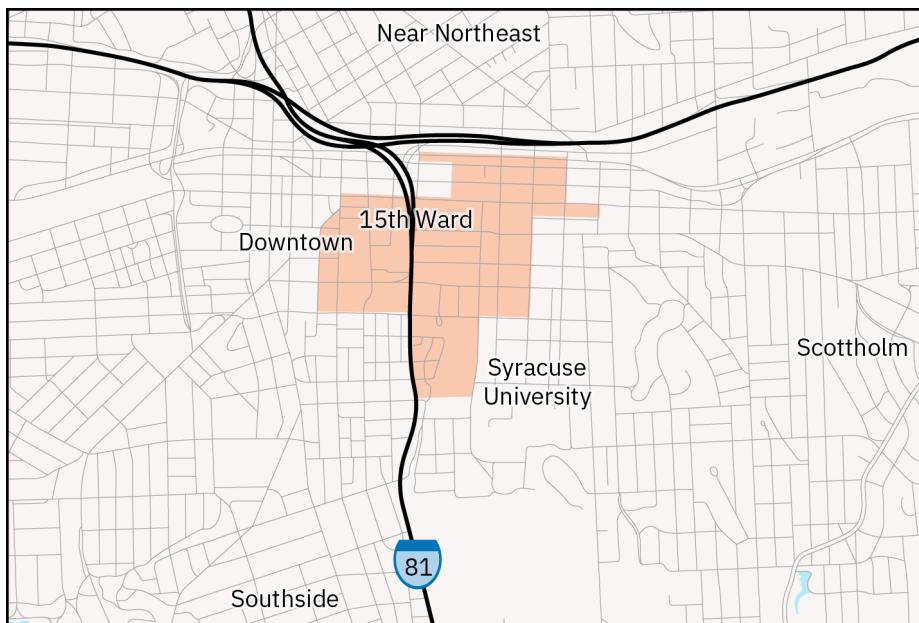

FIGURE 6.5 This map is an example of how the 1956 Federal-Aid Highway Act created highway systems that cut through Black communities. Interstate 81 was designed to break up the 15th Ward, where 90 percent of Syracuse's Black population lived. Homes, businesses, and churches were destroyed, severely disrupting the community and increasing poverty among its residents. (See Sullivan, 2021; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Redlining and residential segregation practices have broad implications today. Residential segregation resulted in a range of social disinvestment, or lack of investment of money in businesses, schools, homes, and infrastructure, in BIPOC communities. Social disinvestment largely dictated the built environment, resulting in poor neighborhood infrastructure, services such as schools and transportation, and employment opportunities (Bailey et al., 2021). Residential segregation is an influential predictor of Black disadvantage (Bailey et al., 2021). Redlining is associated with poor health outcomes, including higher rates of preterm birth, cancer, tuberculosis, maternal depression, and other mental health issues in residents who live in neighborhoods that were once redlined (Bailey et al., 2021). Many factors are related to these differences in health outcomes, such as environmental toxins and the physical impact of persistent psychosocial stressors (Bailey et al., 2021). In contrast, neighborhoods that received high HOLC grades have more tree coverage and lower levels of airborne carcinogens and air pollution; such areas tend to be predominantly White neighborhoods (Bailey et al., 2021).

▶ WHY ARE U.S. CITIES STILL SO SEGREGATED?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-2-the-historical-context-of-structural-racism-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-2-the-historical-context-of-structural-racism-in-the-united-states)

This TED-Ed video recounts the history of the American suburbs, discussing racial covenants, white flight, and the massive freeway projects in redlined areas that further devalued properties and created environmental health injustices.

Watch the video, and then respond to the following questions.

1. What factors do you think drove white flight?
2. How are racial covenants and redlining similar to other racially discriminatory practices in the United States in the past and today?
3. How does residential segregation intersect with poverty and environmental injustice?

Mass Incarceration and Police Violence

Mass incarceration is another manifestation of structural racism in the United States. The United States has one of the highest incarceration rates globally (ACLU, 2023; Bailey et al., 2021; Nellis, 2021; Sawyer & Wagner, 2023). Though the United States makes up less than 5 percent of the world's population, incarcerated individuals in the U.S. make up 25 percent of the world's inmate population (ACLU Washington, 2022). These rates of incarceration,

and in particular the large numbers of young Black men who are incarcerated in the U.S. prison system, are often referred to as **mass incarceration** (Cullen, 2018; Hinton & Cook, 2021). Research has consistently demonstrated racial bias across the U.S. criminal legal system in policing, bail setting, sentence length, prison disciplinary measures, and capital punishment (Bailey et al., 2021; Hinton & Cook, 2021; Nellis, 2021).

After slavery was outlawed and following initial Reconstruction-era civil rights progress, police and prisons in some locations became institutions where White dominance was reasserted (Bailey et al., 2021; Hinton & Cook, 2021). For example, some individuals in law enforcement sanctioned the lynching of Black Americans or used it to police them (Bailey et al., 2021; Hinton & Cook, 2021). Law enforcement also enforced vagrancy laws, jailing individuals for vagrancy and then leasing them to perform agricultural work, essentially compelling formerly enslaved people back into slavery (Bailey et al., 2021; Hinton & Cook, 2021). With the passage of the Civil Rights Act of 1964, lynching and the convict-leasing system became less common.

In the decades following the passage of the Civil Rights Act of 1964, federal legislation has persisted in undercutting the gains it represented. In 1965, President Johnson declared a “War on Crime,” giving the federal government new responsibility for fighting crime within communities. Not solely focused on criminal behavior, this “war” targeted the sociological and economic factors the government believed led to criminality, tasking police and law enforcement officials with monitoring poverty, family breakdown, and youth and young adult restlessness within their communities. Law enforcement presence increased in poor urban neighborhoods mostly comprised of Black Americans, leading to a racial criminalization of young Black individuals on the street. This resulted in **racial profiling**, suspecting an individual of criminal misdeeds based on racial stereotypes rather than on an individual’s behavior (Lassiter, 2021a; Lassiter, 2021b; Laurencin & Walker, 2020).

In 1971, President Nixon’s “War on Drugs” increased law enforcement and penalties for drug possession and imposed mandatory incarceration for drug offenders. Critics have argued that Nixon’s War on Drugs was both racially motivated and an effort to criminalize those individuals who were protesting the Vietnam War, often described as hippies. Through a media campaign, the government sought to suggest to the American public that they should associate anti-war hippies with marijuana and Black individuals with heroin and that they should consider both populations as prone to criminal behavior (Taifa, 2021). Both the War on Crime and the War on Drugs arguably spread fears about supposed Black criminality (Bailey et al., 2021; Hinton & Cook, 2021; Lassiter, 2021a; Taifa, 2021). Following these two presidential declarations, the incarcerated population increased sevenfold, with Black individuals incarcerated at five times the rate of White individuals. In 1981, President Reagan expanded the War on Drugs, allocating more funding to law enforcement, emphasizing incarceration over treatment, and instituting mandatory minimum sentences for drug possession (Hinton & Cook, 2021). The large gap between the amounts of crack and of cocaine powder that resulted in the same minimum sentence reinforces claims that the War on Drugs was racially motivated; 5 grams of crack and 500 grams of cocaine powder resulted in the same minimum five-year prison sentence. Because most crack users were Black, these mandatory minimums resulted in inequitable increases in incarceration rates for nonviolent Black drug offenders (Taifa, 2021).

It is unknown if poverty is a reason why an individual is more likely to perpetrate a crime, but records confirm that poverty renders an individual not only more vulnerable to being arrested but also more likely to be accused of a more severe crime and receive a longer punishment (Hayes & Barnhorst, 2020). Adults experiencing poverty are three times more likely to be arrested than those who are not living in poverty (Hayes & Barnhorst, 2020). The Brookings Institution found the probability that a boy from a family with an income in the bottom 10 percent of income distribution has a 20 times greater risk of being incarcerated in his thirties than a boy from a family with an income in the top 10 percent (Hayes & Barnhorst, 2020).

In 1972, 34 percent of the U.S. Black population lived below the poverty level, and 42 percent of incarcerated Americans were Black (Hinton & Cook, 2021). In contrast, only 10 percent of the White population in 1972 lived below the poverty level. This socioeconomic disparity worsened as the Nixon administration defunded many social welfare programs, resulting in a decrease in access to education and employment opportunities. The 1970s were characterized by increased police presence in low-income neighborhoods, police brutality, and increased incarceration. Discriminatory behaviors among national policymakers and law enforcement continued throughout the next three decades, resulting in a quadrupling in the size of the prison system between 1980 and 2000. This mass incarceration, which still exists in the United States today, disproportionately affects BIPOC populations (Bailey et al., 2021; Hinton & Cook, 2021).

The policies of the 1960s and 1970s that resulted in increased police surveillance in poor, often predominantly BIPOC, urban communities involved the policing of social issues such as alcohol use and an increase in police violence against and killing of Black individuals (Bailey et al., 2021; Green & Peneff, 2022; Lassiter, 2021a). Some of the outcomes of the War on Crime and the War on Drugs include:

- By the mid-1970s, Black and Latino/Latina people were overrepresented in state and federal prisons despite being minority populations within the United States (Hinton & Cook, 2021).
- In Philadelphia, from 1970 to 1974, Black people incarcerated in county jails increased from 50 percent to 95 percent, accounting for more than 62 percent of prisoners state-wide even though Black Americans made up less than 10 percent of the entire state's total population (Hinton & Cook, 2021).
- The 1984 Comprehensive Crime Control Act eliminated parole in the federal prison system (Taifa, 2021).
- The 1986 Anti-Drug Abuse Act established mandatory minimum sentences, including the 100:1 ratio between crack and cocaine powder sentences (Taifa, 2021).
- In 1991, the Supreme Court asserted that mandatory life imprisonment for a first-time drug offense was acceptable (Taifa, 2021).
- The 1994, the Violent Crime Control and Law Enforcement Act resulted in the largest expansion to date of the federal death penalty. The Act treated teenagers as adults, increased the police force, eliminated Pell educational grants for incarcerated people, implemented [the “Three Strikes” law \(<https://openstax.org/r/justice>\)](https://openstax.org/r/justice), and resulted in the creation of many new prisons (Taifa, 2021).

Upon their release, formerly incarcerated individuals often experience the long-term effects of an infectious disease contracted in prison and have a higher risk of death (American Academy of Family Physicians, 2021; Binswanger et al., 2016). Mass incarceration means that these effects disproportionately impact BIPOC individuals.

JASON'S SENTENCE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-2-the-historical-context-of-structural-racism-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-2-the-historical-context-of-structural-racism-in-the-united-states)

This video from the American Civil Liberties Union highlights the story of Jason Hernandez, a 21-year-old who was sentenced to life in prison without parole for a low-level drug crime. Although the judge wanted to give Jason a second chance, he was obligated to enforce mandatory minimum sentencing laws.

Watch the video, and then respond to the following questions.

1. Based on the video, how do socioeconomic factors play a role in mass incarceration?
2. How do mandatory minimum sentencing laws affect families and communities?
3. What role does structural discrimination play in these laws?

A surge in police killing of Black men in the late 1960s led to efforts to curtail police use of force, but it was not until 1985 that the Supreme Court decision in *Tennessee v. Garner* placed restrictions on police use of force. In that case, the Court found that deadly use of force on a fleeing suspect is unconstitutional unless there is cause to believe the suspect poses a significant threat to the officers or the public (Bailey et al., 2021; Green & Peneff, 2022). Even with these restrictions in place, fatal police violence is an ongoing public health threat, disproportionately impacting BIPOC communities and highlighting the persistence of systemic racism (GBD 2019 Police Violence U.S. Subnational Collaborators, 2021 [GBD]; Peebles, 2020). Police killings are a leading cause of death for young Black men in the United States. Recent studies suggest that 1 in every 1,000 Black men are killed by the police, 2.5 times more than White men (GBD, 2021). In 2021, an investigation found that at least 135 unarmed Black men and women had been killed by police in the United States since 2015, and for more than a dozen of the officers involved, the fatal shootings were not their first. In more than half of these cases, the officers were not charged (Thompson, 2021). Aggressive policing in BIPOC communities and the lack of accountability for police officers involved in the deaths of Black people perpetuate disparities and erode trust in law enforcement, discouraging individuals in these communities from reporting crime (Schindler & Kittredge, 2020). Police violence has many indirect effects; racial profiling and surveillance with threats of violence negatively impact the mental health of a community (Bailey et al., 2021).

CASE REFLECTION

Structural Racism

Read the scenario, and then respond to the questions that follow.

Thirty-three-year-old James Cole lives in Chicago and works full-time at a downtown marketing firm. He just graduated with a master's degree in business administration and feels lucky as he reflects on the struggles of his parents and childhood friends. His parents grew up in Chicago in the late 1930s and 1940s, living in apartment complexes within a densely populated area consisting mostly of BIPOC families. When his parents were starting a family, they were unable to secure a mortgage to purchase a house because they were Black. In 1970, the Coles moved into a public housing project on the North Side of Chicago, where James grew up. By the 1980s, the War on Drugs and mass incarceration created an atmosphere of police distrust due to racial profiling. Crime and concentrated poverty increased, and the media portrayed the area as full of drugs and gangs. Many of the Coles' neighbors were incarcerated for drug-related crimes. The community where the Coles resided became undesirable to new businesses and social programming, resulting in overall disinvestment. The school district for the Coles' neighborhood was poorly funded and was considered one of the worst in the state, and many of James's friends did not graduate from high school.

1. How do you think structural racism impacted James and his family?
2. How do you think the Coles' social situation impacted their health?

KNOW THEIR NAMES

This interactive slide show "[Know Their Names \(https://openstax.org/r/interactive\)](https://openstax.org/r/interactive)" offers a brief history of some of the Black people killed by the police in the United States between 2014 and 2021.

Read through the slide show, and then respond to the following questions.

1. What do the victims featured in this slide show have in common?
2. Why do you think these individuals were the victims of police violence?
3. How does racial profiling relate to structural racism?
4. Compare the actions taken in response to these killings. Do the responses seem appropriate? Why? What do you think accounts for the differences in the responses?

6.3 Contemporary Structural Racism and Systemic Inequities in the United States

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 6.3.1 Describe the relationship between structural racism and systemic inequities.
- 6.3.2 Discuss contemporary manifestations of structural racism.
- 6.3.3 Examine current persistent systemic inequities.
- 6.3.4 Explain how structural racism intersects with the social determinants of health.

To illustrate the concept of structural racism, Gee and colleagues (2009) utilize the analogy of an iceberg. The visible part of the iceberg above the water represents overt racism, which is easily recognizable. The larger, mostly hidden base of the iceberg represents structural racism, the often invisible social systems and structures that result in harm of and discrimination against BIPOC individuals (Gee et al., 2009). Structural racism may pose barriers to opportunities that would otherwise promote health and well-being, such as access to high-paying jobs with benefits, safe neighborhoods, quality schools, quality health care, and equitable treatment in the criminal justice system (Braveman et al., 2022). Just as the unseen base of an iceberg is more dangerous to a ship than its tip, structural racism can be more dangerous than overt racism, as it positions BIPOC individuals at a significant disadvantage across several domains of living, impacting health in ways that are not as easily discernable (Braveman et al., 2022). Political disempowerment, residential segregation, unequal financial practices, unfair

treatment in the criminal justice system, and environmental health injustice are all examples of current structural racism and persistent systemic inequities.

The Relationship Between Structural Racism and Systemic Inequities

As discussed, structural racism results in institutional policies, systems, laws, and practices that limit the opportunities, resources, and power of individuals based on race (Braveman et al., 2022), resulting in systemic inequities. Inequities create inequalities in health care, education, housing, and employment opportunities. Structural racism and systemic inequities are partners, existing together and creating unequal systems across all of society. Put simply, structural racism creates unequal opportunities to achieve positive outcomes.

Structural racism results in systemic inequities even when controlling for income level. College-educated Black individuals are more likely to experience unemployment and have lower levels of income and accumulated wealth than their White counterparts (Churchwell et al., 2020).

THE RACE GAP: BLACK WHITE

The Reuters Graphics slideshow “[The Race Gap: Black White \(https://openstax.org/r/reuters\)](https://openstax.org/r/reuters)” explores the gap between Black and White Americans from birth to death, highlighting the systemic disadvantages still present in American life more than 150 years after the abolishment of slavery.

View the slideshow, and then respond to the following questions.

1. The slideshow mentions that disparities persist despite policies and laws intended to address them. Why do you think these policies and laws have failed to eliminate these disparities?
2. In what ways did structural racism create these disparities?
3. How do redlining policies have lasting effects on many of the disparities mentioned in this slideshow, including food insecurity, quality of education, and access to health care?

Political Disempowerment

Since the passage of the 15th Amendment in 1870 secured the right to vote for all men—including non-White men—groups of White Americans have engaged in voter suppression efforts to politically disenfranchise people of color. During the Jim Crow era, voter suppression was prevalent in many states, with White supremacist groups engaging in violent intimidation and governments selectively applying restrictions and laws such as a poll tax and literacy tests. As recently as 2023, many states were considering restrictive voting legislation, such as requiring voter identification, eliminating Sunday voting, limiting mail-in voting, and consolidating polling places. A voting bill or law is considered restrictive when it includes one or more stipulations that make it more difficult for eligible citizens to register to vote, stay on the voter rolls, or cast a vote as compared to existing state law (Brennan Center for Justice [BCJ], 2022). Requiring photo identification, decreasing available times to vote, and creating longer wait times to vote due to consolidated locations disproportionately affect low-income and BIPOC voters due to inflexibility of work schedules, transportation difficulties, and difficulty in obtaining photo identification (Braveman et al., 2022; BCJ, 2022).

Residential Segregation

Residential racial segregation in the United States remains high despite the Fair Housing Act of 1968, which outlawed racial discrimination in housing. Almost three-quarters of the neighborhoods that HOLC graded as hazardous in the 1930s are now considered neighborhoods of color with low-to-moderate income (Mitchell & Franco, 2018). These federal policies kept BIPOC communities living in low-income areas, ensuring systemic inequities in health care access, educational opportunities, employment opportunities, transportation, and health outcomes. For example, the Boston neighborhoods redlined in 1938 still rely on limited bus service, while better-funded commuter rail and subway systems serve other portions of the city (Hostetter & Klein, 2018).

Racial segregation is directly associated with an economic disadvantage, as many individuals gain wealth through equity in their homes. The new homes built in suburban areas during the time of the white flight sold for twice the national median income in the 1940s and 1950s; those same homes sell for almost eight times the national median income today, illustrating how home ownership can create wealth (Gross, 2017). Denying Black Americans the

opportunity to own a home denied them this wealth-creation opportunity, contributing to economic and social inequities. Racial segregation is also associated with limited opportunities for upward mobility due to lack of employment options and poor-quality schools. BIPOC individuals are more likely than their White counterparts with similar incomes to live in areas with concentrated disadvantage (Braveman et al., 2022). Today, once-redlined neighborhoods are more likely to have a majority BIPOC population with lower incomes and overall lower home values (Perry & Harshbarger, 2019).

▶ THE RACIAL DISPARITIES OF MORTGAGE LENDING

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states)

In this *Good Morning America* video, reporter David Scott shares his investigation highlighting racial disparities in mortgage lending in the United States.

Watch the video, and then respond to the following questions.

1. Why do you think there are still widespread racial disparities in mortgage lending?
2. Why do you feel the Fair Housing Act hasn't been more effective in reducing disparities in home ownership?
3. Do you see a path forward to changing these behaviors? If so, describe what you see; if not, explain why.

Financial Practices

Current financial practices continue to perpetuate structural racism, with echoes of the HOLC redlining scheme. Federal loan programs from the mid-1900s through today have greatly increased homeownership among White Americans, while BIPOC neighborhoods have largely experienced disinvestment. While redlined maps are no longer in use, their legacy continues as home values in racially segregated neighborhoods do not appreciate at the same rate as homes in mostly White neighborhoods (Braveman et al., 2022; Lynch et al., 2021; Yearby et al., 2022). Differences in homeownership, home values, and credit scores by race persist in areas that were formerly redlined. Current examples of discriminatory public and private financial practices include check cashing services and payday lenders. Businesses that offer check cashing services afford their clients the ability to get cash immediately from their checks for a fee. While individuals with bank accounts are able to deposit checks into their account and withdraw the money without any fees after the check clears, often in 2–3 days, individuals who use check cashing services must pay a fee—perhaps 2 percent of a check's face value, or \$2 for every \$100 cashed (Davies, 2017). Payday lenders offer short-term payday loans with high interest rates that are due the next pay day. These types of loans are often considered predatory as they are expensive, can damage credit scores if they are not paid back in full, and can lead to debt collection issues (National Association of Consumer Advocates, n.d.). Such services have a history of disproportionately targeting BIPOC communities, further contributing to the inability of the people in these communities to accumulate wealth (Braveman et al., 2022; Lynch et al., 2021).

▶ THE SURPRISING LOGIC BEHIND THE USE OF CHECK CASHERS AND PAYDAY LOANS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states)

This *PBS News Hour* video investigates the business of check cashers and payday lenders. Check cashers are often considered predatory, as they charge a fee to cash paychecks, but for many Americans who are living in poverty without any savings, check cashers are often the only way to get cash the same day. This video discusses arguments for and against these services.

Watch the video, and then respond to the following questions.

1. Do you think check cashing and payday lending practices are predatory? Why or why not?
2. Are check cashing services helpful or harmful? What about payday loans?
3. Is expensive credit better than no credit? Why or why not?
4. What solutions to larger issues could help alleviate the need for check cashing and payday lending services? How would this relate to the social determinants of health?

The Social Security Act (SSA) of 1935 created a system of employment-based insurance and income compensation to care for adults in retirement age (Bailey et al., 2017). To secure congressional votes in the South, the SSA deliberately excluded agricultural workers and domestic servants as these occupations were largely filled with Black men and women (Bailey et al., 2017). Because it excluded Black individuals, the SSA afforded the primarily White recipients more opportunity to acquire wealth and transfer it to future generations, whereas those without the benefit of the SSA often become dependent on adult children after retirement, further relegating BIPOC communities and families to lower wealth accumulation (Bailey et al., 2017).

Public schools in the United States depend on local property taxes as a large part of their budgets. In racially segregated areas, the lower-income neighborhoods, largely composed of BIPOC individuals and low-income White individuals, have lower property tax revenues that result in resource-poor public schools. Property taxes are lower in these neighborhoods due to redlining. While low-income White individuals are affected by this issue, it disproportionately affects BIPOC individuals because structural racism has resulted in higher levels of household and community poverty (Braveman et al., 2022).

Criminal Justice System

Structural racism in the U.S. criminal justice system manifests in racial patterns of incarceration. The disproportionate burden of incarceration on BIPOC individuals reflects pervasive prejudicial policing and biased sentencing practices (Braveman et al., 2022). Incarceration carries a negative stigma that perpetuates a cycle of disadvantage, with fewer employment and economic opportunities affecting incarcerated persons' families and communities. As discussed, police violence continues to be among the leading causes of death in Black men. Evidence comparing Black victims and White victims killed by police suggests inequitable treatment between the two races with a fatality rate three times higher among Black victims than White victims and Black victims more likely to be unarmed than their White counterparts (Braveman et al., 2022; DeGue et al., 2016; Laurencin & Walker, 2020). Systemic racism includes laws and policies but also the norms that guide routine practices. In the case of police, implicit biases play a role in the assumption that Black men are dangerous, creating distrust and disparities in police use of force between Black and White individuals (Braveman et al., 2022; Hinton et al., 2018; DeGue et al., 2016). At the intersection of the police and educational systems, the practice of schools involving law enforcement more often for misbehaving Black students than for misbehaving White students, increasing the risk that Black students will be incarcerated, reflects systemic racism. Additionally, school systems discipline Black students with more suspensions and expulsions than they do other students. These practices are based not on law but on prevalent, deeply rooted discriminatory attitudes (Braveman et al., 2022).

LAVETTE'S CHOICE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states)

This ACLU video highlights the story of Lavette Mayes, a single mother arrested after a fight, who serves 14 months in jail because she is unable to afford her pretrial bail of \$25,000. The video explores how the cash bail system has transformed into a for-profit system where higher-income individuals can avoid serving pretrial jail time while lower-income individuals are unable to afford to stay out of pretrial jail.

Watch the video, and then respond to the following questions.

1. How do police profiling, poverty, and incarceration intersect with the social determinants of health?
2. Do you feel pretrial detention is an equitable practice? Why or why not?

Environmental Health Injustice

Like many other facets of systemic racism in the United States, environmental injustices and disparities affecting BIPOC communities often stem from federally sponsored, racially motivated residential segregation. When HOLC and FHA redlined and labeled neighborhoods as hazardous, business disinvestment occurred, followed by a lack of insurable mortgages in these neighborhoods. Such changes made the way for industry to move in with coal-fired power plants, bus garages, and hazardous waste disposal plants, mostly in low-income BIPOC communities (Bailey et al., 2017; Braveman et al., 2022). In addition, most redlined neighborhoods were in urban areas where

widespread community disinvestment resulted in less green space and tree canopies and increased urban heat exposure. The Flint, Michigan, water crisis is an example of both systemic racism and environmental injustice affecting a town that is largely composed of BIPOC individuals, reflecting the history of segregation. In April 2014, the city of Flint switched to an untreated water source that ultimately corroded the water pipes, resulting in high levels of lead leaching into the city's drinking water. Despite months of complaints, it was well over a year before the city took any action. The city changed the Flint water supply, but this was ineffectual since the pipes were already corroded; they continue to leach contaminants into the residents' water (Ruckart et al., 2019). See [Social Determinants Affecting Health Outcomes](#) for more information. The Flint water crisis demonstrates the disinvestment in infrastructure and officials' lack of attention to the concerns of BIPOC individuals, resulting in negative long-term health impacts (Braveman et al., 2022).

Highways and associated traffic pollutants running through neighborhoods and the introduction of hazardous waste disposal plants and coal-fired power plants have resulted in significant environmental injustices in majority-BIPOC communities. These exposures are linked to adverse health outcomes such as asthma, adverse birth outcomes, and cancer (Swope et al., 2022). The legacy of redlining and the 1956 Federal-Aid Highway Act continue to shape the environmental exposures of BIPOC communities (Kowalski, 2019; Lane et al., 2022). The pollutant gradients within urban areas for nitrogen dioxide and particulate matter, both markers of air pollution, are significantly higher in former redlined neighborhoods than they are in other neighborhoods (Bose et al., 2022; Lane et al., 2022).

THE ROOTS OF HEALTH INEQUITIES

Asthma

The history of redlining and its resultant domino effect of social disinvestment resulted in higher levels of air pollution in BIPOC and low-income communities and higher rates of asthma in individuals living in those communities. The racial and ethnic disparities in asthma are a result of a complex interplay of factors including structural racism, residential segregation, discriminatory policies, and the SDOH, along with lifestyle and biological determinants. Black, Hispanic, and Indigenous people disproportionately bear the burden of asthma in the United States with the highest rates and numbers of deaths and hospitalizations. Black Americans are:

- one and one-half times more likely to have asthma,
- five times more likely to visit an emergency department due to asthma, and
- three times more likely to die from asthma.

(See Asthma and Allergy Foundation of America, 2020; Bose et al., 2022; Lane et al., 2022; Perez & Coutinho, 2021.)

The Congress for the New Urbanism (CNU) is a strong advocate for replacing aging highways that run through neighborhoods with city boulevards, housing, and green spaces, transforming the urban highway corridors of the past (CNU, n.d.-b). Examples of the kinds of completed projects for which Highways to Boulevards advocates include the Big Dig in Boston, Massachusetts; the Mandela Parkway in Oakland, California; and the Riverfront Parkway in Chattanooga, Tennessee (CNU, n.d.-b). For a complete listing of completed Highway to Boulevard projects, [visit this website \(<https://openstax.org/r/cnu>\)](https://openstax.org/r/cnu).

HOW RACISM SHAPED THE INTERSTATE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states>\)](https://openstax.org/books/population-health/pages/6-3-contemporary-structural-racism-and-systemic-inequities-in-the-united-states)

In this *NPR Morning Edition* news episode, "A Brief History of How Racism Shaped Interstate Highways," reporter Noel King speaks with Professor Deborah Archer about the history of racism and redlining in creating the interstate highways.

Listen to the episode, and then respond to the following questions.

1. Do you think these highway projects were purposefully designed to keep residential populations segregated? Why or why not?

2. How would you describe the relationship between these highway projects, racism, and environmental health?

Intersection of Structural Racism and the Social Determinants of Health

The social determinants of health (SDOH) are the nonmedical factors that impact health outcomes (CDC, 2022b). [Social Determinants Affecting Health Outcomes](#) discusses the SDOH in detail. Examples of SDOH include access to safe housing, exposure to discrimination or violence, income level, and language and literacy skills (ODPHP, 2020d). Healthy People 2030 names structural racism as one of the SDOH given its pervasive and often invisible reach into all social practices (Bailey et al., 2017; ODPHP, 2020b). The historical roots of structural racism tie directly into the SDOH, as this racism has consigned BIPOC communities to an inferior or second-class status (Braveman et al., 2022). Put more succinctly, structural racism is further upstream than the SDOH (Churchwell et al., 2020; Lynch et al., 2021). The following are key examples of the ways in which structural racism intersects with the SDOH.

- Safe housing: Structural racism negatively affects income level due to the far-reaching and lasting implications of historical residential segregation. HOLC and FHA redlining are examples of structural racism that limited opportunities for BIPOC families to purchase homes and to benefit from intergenerational wealth transfer, contributing to the lower-than-average income and wealth of BIPOC families. Black Americans have approximately one-tenth of the wealth of White Americans, have fewer assets, and are less likely to own their homes, own a business, or have a retirement account (Hanks et al., 2018). Because of structural racism, residential segregation in America continues, with more BIPOC families living in lower-income neighborhoods (Lynch et al., 2021; Ray et al., 2021; Zonta, 2019). For all of these reasons, structural racism presents a barrier to safe housing for BIPOC families.
- Exposure to discrimination or violence: Structural racism exposes people to discrimination or violence in the form of biased policing practices, biased sentencing policies, and the mass incarceration of BIPOC individuals. This exposure results in a myriad of adverse outcomes for those affected (Bailey et al., 2021; Braveman et al., 2022), touching upon the SDOH in discrimination, violence, lower income, and barriers to safe housing.
- Language and literacy: Structural racism negatively affects language and literacy skills due to the lack of access to quality schools in predominantly BIPOC neighborhoods and due to the biased treatment of BIPOC students within the educational system (Quick & Kahlenberg, 2019; Williams et al., 2019).

6.4 Structural Racism and Systemic Inequities in U.S. Health Care

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 6.4.1 Explain how structural racism and systemic inequities manifest in the U.S. health care system.
- 6.4.2 Discuss how structural racism and systemic inequities affect population health outcomes.
- 6.4.3 Assess current programs addressing structural racism and systemic inequities in health care.
- 6.4.4 Describe the role of the nurse in addressing structural racism and systemic inequities.

The direct effects of racism and implicit bias, discriminatory policies in health insurance access and coverage, the effects of discriminatory mass incarceration, and the lasting impact of discriminatory policies in residential segregation led to negative health outcomes for BIPOC communities. Residential segregation, one of the principal drivers of systemic inequities resulting from structural racism, results in lower wealth accumulation in BIPOC families, educational inequities driving employment disparities in BIPOC communities, and the disproportionate burdens of environmental hazards, decreased access to quality foods, and lack of adequate transportation that results from disinvestment in communities (Lynch et al., 2021).

Racism and Implicit Bias in Health Care

In health care, personally mediated discrimination often manifests as an implicit bias against certain clients. Several studies have confirmed that health care professionals' implicit biases negatively affect the quality of client care they provide and correlate with discriminatory behavior (Greenwald et al., 2022; Sabin, 2022). Nurses are not immune to implicit biases or their effects (Hostetter & Klein, 2018; Ochs, 2023). [Culturally and Linguistically Responsive Nursing Care](#) has more information on implicit bias. The following are examples of how implicit racial bias manifests in the health care setting:

- BIPOC clients receive fewer cardiovascular interventions than their White counterparts, resulting in higher cardiovascular mortality rates (Bridges, 2018; Eberly et al., 2021; Emory University, 2023; Quach, 2020).
- BIPOC clients are less likely to be prescribed pain medications than their White counterparts (The Joint Commission, 2023).
- BIPOC clients receive fewer renal transplants than their White counterparts (The Joint Commission, 2023).
- Black women are more likely than White women to die after being diagnosed with breast cancer (The Joint Commission, 2023).
- Black men are less likely to receive chemotherapy and radiation therapy for prostate cancer and more likely to have their testicles removed than White men (The Joint Commission, 2023).
- BIPOC clients are more likely than White clients to be blamed for being “too passive” about their health care (The Joint Commission, 2023).

Discriminatory Policies in Health Insurance Access and Coverage

Occupational segregation refers to separating workers by race into certain industries, resulting in a disproportionate representation of one race in a sector of the workforce. This practice has its roots in slavery, where two-thirds of enslaved individuals were forced to work on farms while the remaining third worked in domestic settings. After slavery was abolished, many former confederate southern states created the Black Codes, essentially forcing the former slave population to continue to work in low-wage agricultural or domestic roles and ensuring ongoing disparities in wages and working conditions between BIPOC and White workers (Zhavoronkova et al., 2022). The National Labor Relations Act of 1935 further exacerbated occupational segregation. While it expanded union rights for workers, resulting in higher wages and benefits, these rights did not apply to service, domestic, or agricultural industries, thereby cutting out BIPOC workers from these protections (Yearby et al., 2022). Today, BIPOC workers are overrepresented in domestic and care occupations, such as home health aides, personal care aides, and childcare workers, and in service roles such as janitorial staff, drivers, and laborers (Zhavoronkova et al., 2022). These are often low-wage jobs that do not offer or provide health insurance.

During the Civil Rights era of the 1960s, the federal government created Medicare and Medicaid, public safety-net programs that aimed to cover health care costs for qualified individuals who lacked health insurance. Medicare is a federal health care program that covers the older adult population and individuals with disabilities, whereas Medicaid is a joint federal and state health care program for select categories of individuals such as individuals with lower incomes, pregnant people, children, older adults, and individuals with disabilities (Yearby et al., 2022). By not enforcing fair practices, the federal government allowed Medicare and Medicaid to be administered in ways that perpetuated racial discrimination and health care inequities and disproportionately negatively affected BIPOC individuals. For example, even if nursing homes denied admission to BIPOC clients, as long as the homes made it look like they were open to everyone by, for example, making an effort to use nondiscriminatory language in their marketing materials, they could participate (Yearby et al., 2022).

The Affordable Care Act (ACA) expanded Medicaid, but a Supreme Court decision in *National Federation of Independent Business v. Sebelius* made the expansion optional for states, creating a coverage gap in states that chose not to expand for those individuals who are unable to afford private insurance but do not meet the tight eligibility criteria of traditional Medicaid. This gap largely affects minority populations, 60 percent of whom are BIPOC, and twice as many Black individuals as White and Latino individuals (Yearby et al., 2022). Some states have attempted to impose eligibility restrictions on Medicaid expansion, including work-reporting requirements rooted in racist assumptions about the work ethic of Black individuals (Yearby et al., 2022).

Financing is another area of concern. Federal law requires that Medicaid reimbursement be sufficient to ensure equitable access to high-quality health care for its beneficiaries. However, Medicaid payments to health care providers are low compared to commercial health insurance plans, leading many providers to drop clients who have Medicaid insurance. These providers often cite low Medicaid reimbursement levels (i.e., payments for services rendered) as the reason they will not accept clients on Medicaid insurance (Yearby et al., 2022). This creates a barrier to health care access for clients who do not have commercial or employer-sponsored health insurance.

The federal government has attempted to institute health care payment reform to improve quality of care and reduce costs of care by placing more accountability for health outcomes on the health care provider. One popular model for payment reform, value-based programs, as discussed in [Demographic Trends and Societal Changes](#),

rewards health care providers for positive health outcomes by reimbursing health providers and systems a flat fee for a health condition. If the client has a positive outcome from treatment and only requires one or two visits, the health care provider or system gets to keep most of the flat fee reimbursement from the insurance plan. For clients who develop complications or require multiple subsequent visits arising from the health condition, the health care provider or system is responsible for the costs if they exceed the flat fee reimbursement that was already paid. This payment system incentivizes health care providers and systems to provide excellent quality care. One downside of this payment system is that it is “color-blind”; safety-net providers that care for low-income BIPOC clients may be penalized for health outcomes that result from poorer overall health due to the SDOH and structural racism rather than from the quality of clinical care provided (Yearby et al., 2022). Pay-for-performance programs are very common in the United States and financially reward providers who care for mostly affluent and predominantly White populations with better general health (Yearby et al., 2022).

Despite increases in health insurance coverage since the passage of the ACA, BIPOC individuals are still more likely to be uninsured than White individuals (Yearby et al., 2022). Medicaid expansion, as supported by the ACA, is associated with lower rates of uninsured individuals. However, 12 states with higher percentages of historically marginalized groups currently do not provide this additional coverage (Rudowitz et al., 2023). This contemporary lack of equitable access to high-quality health care is a result of structural racism in U.S. health care policy, as is the requirement for employer-based health insurance excluding agricultural and domestic industries (Yearby et al., 2022). Outside of the discriminatory policies in health insurance access, structural racism in the form of residential segregation has negatively impacted health care access and quality at all levels. Systematic disinvestment in communities from both the public and private sectors has left many BIPOC communities at a socioeconomic disadvantage, making it difficult for these communities to attract experienced and high-quality primary care providers and specialists (Bailey et al., 2017). Studies have demonstrated a lack of investment in health promotion resources in these communities and that overall health care infrastructure and services are inequitably distributed, exposing BIPOC clients to substandard and racially biased care (Bailey et al., 2017).

Discriminatory Mass Incarceration

Racial profiling and biased policing, along with mass incarceration, particularly of BIPOC men, result in harmful exposures from the stress of police profiling, being incarcerated, and lifelong stigmatization. Within the general population that has experienced incarceration, there are higher rates of mental health disorders, hypertension, asthma, cancer, arthritis, tuberculosis, hepatitis C, and HIV (ODPHP, 2020c). The mass incarceration of a disproportionate number of Black individuals in the U.S. prison system means that a disproportionate number of Black Americans experience these negative health outcomes. The heavy disease burden these individuals experience in prison has implications for their return to the community. Post-incarceration, formerly incarcerated individuals experience a lifelong lack of access to resources and opportunities needed for good health, such as access to employment, housing, and health care (Braveman et al., 2022). Individuals who were formerly incarcerated on a felony drug charge are often denied access to food assistance programs, public housing, and other services (Wildeman & Wang, 2017). Additionally, stress from discrimination and police profiling is associated with higher risks of chronic diseases such as heart disease, hypertension, and obesity (Braveman & Dominguez, 2021; Braveman et al., 2022).

Pervasive Lingering Effects of Racial Residential Segregation

The policies and practices of racial residential segregation have resulted in the populations living in low-income and mostly BIPOC neighborhoods experiencing more physical and chemical hazards, increased psychosocial stressors, increased policing, lack of access to quality food, lower-quality school districts, transportation difficulties, and reduced availability of quality health care and pharmacy services (Williams et al., 2019). Economic disadvantage and racial segregation result in poorer health due to environmental factors such as less tree canopy, increased airborne hazards, higher inner-city temperatures, increased exposure to air pollution, toxic waste, mold in substandard housing, and other environmental hazards. Lower levels of income, poorer-quality education, and discrimination in housing mean that BIPOC families may not be able to access healthier residential living and often suffer racial disparities in health (Braveman et al., 2022; Lynch et al., 2021).

Numerous epidemiologic studies have linked segregation to increased risk of low birth weight and preterm birth for Black babies (Williams et al., 2019). Segregation is also associated with later-stage diagnoses for breast and lung

cancers with lower survival rates in Black clients (Williams et al., 2019). Increased rates of asthma and utilization of the emergency department for asthma care are associated with historically redlined neighborhoods, likely related to environment injustice; there is also increased availability of alcohol, use of alcohol, and urban violence in these communities (Haley et al., 2023; Lynch et al., 2021). Self-reported racial discrimination is associated with adverse cardiovascular outcomes, including obesity, hypertension, engagement in high-risk behaviors such as alcohol use, and poor sleep. Self-reported racial discrimination also revealed that those who perceived discrimination were less likely to seek medical care and adhere to medical plans (Williams et al., 2019).

How Structural Racism and Systemic Inequities Affect Population Health

There is a direct connection between structural racism and the resulting systemic inequities in health outcomes for certain populations. Structural and interpersonal racism is at the foundation of health disparities and inequities, with an unacceptable and widespread impact on BIPOC communities (CDC, 2021). These adverse health disparities exist in maternal-child health outcomes, cardiovascular care and outcomes, asthma care, cancer care and outcomes, diabetes care, and mental health care, with a life expectancy 4 years lower among Black Americans than among White Americans (CDC, 2021). Infant mortality rates among Black childbearing families are 11.11 infant deaths out of every 1,000 births, compared with the overall rate in the United States of 5.96 infant deaths out of every 1,000 births (ODPHP, 2020a).

The COVID-19 Pandemic

The COVID-19 pandemic illustrates how structural racism and systemic inequities affect population health. The pandemic exposed and intensified longstanding racial health disparities. The morbidity and mortality rate for COVID-19 is disproportionately higher for BIPOC clients in comparison with White clients, with data between March 2020 and June 2021 demonstrating that BIPOC clients endured hospitalization rates almost three times the rate of White individuals (U.S. Government Accountability Office, 2021; Yearby et al., 2022). The COVID-19 pandemic highlighted the cumulative impact of discrimination on health outcomes, reflecting differences in susceptibility to disease, occupational exposure, access to care, clinical prognosis, and outcomes (Selvarajah et al., 2022).

As discussed, race is associated with socioeconomic status, with structural racism designating many BIPOC populations to lower socioeconomic status (Lopez et al., 2021). Members of BIPOC communities are more likely to live in overcrowded, multigenerational households. They are also more likely to have jobs that require on-site presence such as transportation workers, grocery store employees, nursing aides, construction workers, and household workers (Andraska et al., 2021; Lopez et al., 2021). These social factors place BIPOC communities at higher risk for COVID-19 infection. Additionally, due to the chronic stressors of structural racism, discrimination, and overall marginalization, this population often has chronic medical conditions, such as hypertension, diabetes, liver disease, and obesity, that are associated with more severe COVID-19 infection (Andraska et al., 2021; Lopez et al., 2021). Overall decreased access to health care accounts for the significant disparities in COVID-19 health outcomes by race ([Figure 6.6](#)). This is a preventable, socially mediated disparity.

The incarcerated population also experienced a disproportionate burden of COVID-19 disease, with a case rate that was almost six times higher and a death rate that was three times higher than that of the non-incarcerated population (Andraska et al., 2021). These statistics are unsurprising given that incarcerated populations have similar comorbidities to BIPOC communities in general, coupled with living in a communal setting without autonomy, fostering the rapid transmission of the disease (Andraska et al., 2021).

FIGURE 6.6 During the COVID-19 pandemic, individuals often waited in long lines for hours to obtain testing. Some BIPOC communities lacked access to COVID-19 screening, testing, and vaccination sites. (credit: “COVID-19 Testing Site in Times Square, New York City” by Anthony Quintano/Flickr, CC BY 2.0)

Looking at the COVID-19 pandemic through a population health lens of structural racism, the reasons for the disproportionate BIPOC morbidity and mortality are multifaceted across public health practice levels. This list provides a few examples of the broad-reaching effects, on health in particular, of structural racism and is adapted from the work of Selvarajah et al. (2022).

- Individual level
 - Increased occupational exposures to COVID-19
 - Prevalence of comorbidities associated with COVID-19 severity and mortality
- Community level
 - Neighborhood and housing
 - Difficult for multigenerational households to self-isolate or physically distance
 - Unequal exposures to environmental toxins and air pollution that can exacerbate COVID-19 symptoms and outcomes
- Systems or population level
 - Health systems
 - Minority health care workers were more likely to be in higher-risk areas and were less likely to receive adequate personal protective equipment.
 - There were vaccine and testing site inequities as BIPOC communities experienced barriers in accessing the vaccine and testing sites (Sina-Odunsi, 2021). Access barriers are related to inflexible hours of health care or testing sites, transportation difficulties, and lack of available sites to administer vaccines (Johnson, 2021; Selvarajah et al., 2022).
 - BIPOC communities experience structural barriers to accessing health care.
 - BIPOC communities often have a distrust in the health system.
 - Government
 - Ineffective public health messaging with mixed messaging resulted in unclear public health messages regarding masking, testing, vaccines, medications to treat COVID-19, and isolation periods (Ngo, 2022). In a systematic scoping review, Kalocsanyiova et al. (2022) found health inequities and communication inequities were closely associated, meaning BIPOC clients, who were disproportionately impacted by COVID-19, also were negatively impacted by a lack of health

- communication either from a lack of access to information, a lack of trust, language barriers, and/or barriers to health literacy.
- Discrimination was rooted in the pandemic response with Sinophobia, anti-Chinese sentiment, and an overall increase in attacks on Asian Americans.

The intersections of structural racism with health disparities affecting BIPOC communities, the socioeconomic status of BIPOC populations, and community disinvestment are a complex web of interrelated cycles of social exclusion resulting in stark health inequities. The COVID-19 pandemic highlighted these inequities but did not create them.

CASE REFLECTION

Structural Racism and Health Disparities

Read the scenario, and then respond to the questions that follow.

Earlier, the chapter introduced James and his family, who grew up and live in Chicago. James and his wife Tina are expecting their first child. Tina, a generally healthy 30-year-old, is 7 months pregnant and feeling tired but well overall. She has had an uneventful pregnancy thus far. One morning Tina wakes up with a bad headache that does not go away with acetaminophen. She calls her health care provider, who tells her to rest and drink fluids as no other medication can be given for her headache. Tina follows this advice, but the headache worsens, and she thinks her face looks swollen. She calls her provider and requests a same-day appointment.

At the appointment, Tina relays her concerns of the worsening headache and swollen face to the nurse and then to her health care provider. The provider finds a reassuring fetal heart rate and tells Tina that the baby is fine. The provider tells Tina to go home and reinforces using acetaminophen, rest, and fluids. Tina asks if it is normal to have a headache and swollen face, and the provider says, “Headaches are common, and I don’t think your face is swollen—it looks proportionate to your body. It’s normal for expectant mothers to be vigilant, but I’m sure it’s nothing.” Tina goes home but feels as if the provider dismissed her complaints. She calls her mother-in-law and expresses her frustrations. Tina’s mother-in-law asks about her blood pressure reading, and Tina says, “I don’t think they took it. They rushed me in and out. They only checked the baby’s heart rate.” Tina’s mother-in-law tells her she should go back to the clinic the next day.

Tina goes to bed that night with a severe headache. James is concerned, but he doesn’t want to worry her, so he doesn’t say anything. He plans to go to the provider visit tomorrow. In the morning, when Tina wakes up, her face and hands are very swollen, and she is crying in pain. They go straight to the emergency department, where Tina is diagnosed with eclampsia and undergoes an emergency Caesarean section to deliver the baby.

1. What factors contributed to the delayed diagnosis of eclampsia for Tina?
 2. What screenings should the nurse or provider have conducted with Tina?
 3. Why do you think there are health disparities in maternal morbidity and mortality by race and ethnicity?
 4. How can a community health nurse address these disparities from a population-health standpoint?
-

Physiological Response to Racism

Discrimination affects health via the over-activation of stress pathways. When the body perceives a threat or danger, the neurological, endocrine, and immune biological systems activate to prepare for it with the fight-or-flight response. Each activates the sympathetic nervous system, the hypothalamic-pituitary-adrenal (HPA) axis, and increasing amounts of inflammation (Selvarajah et al., 2022). This results in a state of general alertness with an increased heart rate, blood pressure, and circulating energy through elevated blood glucose levels and fat breakdown from the effects of cortisol and norepinephrine. This is a useful system when confronted with an acute, potentially dangerous situation, but when this response occurs for an extended period of time, termed **allostatic load** (AL) or allostasis, it gives rise to adverse physiological effects (Baker, 2021; Obeng-Gyasi et al., 2022; Selvarajah et al., 2022). Structural racism is a form of discrimination that is often perceived as a threat that activates these stress response pathways. Facing structural racism over a lifetime leads to chronic activation of this response that ultimately favors short-term survival over long-term health, resulting in physiological wear and tear and dysregulation at the cellular level (Baker, 2021; Obeng-Gyasi et al., 2022; Selvarajah et al., 2022).

AL is a measure of physiological dysregulation due to cumulative chronic stress (Rodriguez et al., 2019; Selvarajah et al., 2022). Researchers have studied AL extensively in the setting of structural discrimination and racism; it can be measured from biomarkers such as blood pressure, albumin, hormone levels, cholesterol levels, and C-reactive protein levels among others (Churchwell et al., 2020; Obeng-Gyasi et al., 2022; Rodriguez et al., 2019). High AL is associated with increased overall mortality of 22 percent and increased cardiovascular-related mortality of 31 percent across 17 studies (Churchwell et al., 2020; Parker et al., 2022; Robertson et al., 2017). Other studies specifically looking at Black–White mortality disparities independent of socioeconomic status or behavioral risk factors also found the burden of AL correlates with higher mortality among Black clients (Duru et al., 2012; Obeng-Gyasi et al., 2022). Exposure to discrimination can even perpetuate adverse health effects in subsequent generations via epigenetic changes, that is, changes in the way genes in the body work precipitated by the environment and lifestyle behaviors (CDC, 2022d; Selvarajah et al., 2022). These individuals face epigenetic aging, where biological age exceeds chronological age, which is a predictor of coronary heart disease, diabetes, and premature mortality (Baker, 2021; Obeng-Gyasi et al., 2022; Selvarajah et al., 2022). “Maternal exposure to discrimination is associated with fetal exposure to excess cortisol, fetal HPA axis activation, and higher rates of low birthweight” (Selvarajah et al., 2022, p. 2112).

THE ROOTS OF HEALTH INEQUITIES

Maternal Mortality—A Public Health Crisis

A maternal death is the death of an individual while pregnant or within 42 days of the termination of pregnancy from any cause related to the pregnancy or its management (Hoyert, 2023). The U.S. maternal mortality rate has increased significantly across all races and ethnicities. In 2019, the maternal mortality rate was 20.1 maternal deaths per 100,000 live births, and in 2021, the maternal mortality rate was 32.9 maternal deaths per 100,000 live births (Hoyert, 2023). BIPOC individuals disproportionately bear the burden of the maternal and infant mortality rates within the United States. The CDC has determined that over 80 percent of pregnancy-related deaths are considered preventable; consider these statistics (Trost et al., 2022):

- Non-Hispanic Black women are 3.5 times more likely to die in pregnancy or during the postpartum period than non-Hispanic White women.
- Infants born to Black women are more than twice as likely to die in comparison to infants born to White women.

Structural racism and discrimination along with differences in health insurance coverage and access to care are some of the major factors driving these disparities in maternal and infant morbidity. However, even after controlling for income and health insurance status, studies have demonstrated BIPOC women are less likely to receive routine medical care and overall experience a lower quality of care, highlighting the prominent role of provider discrimination. Additionally, the AL of the chronic stress of racism and discrimination place BIPOC individuals at higher risk for pregnancy-related complications that threaten their lives and the lives of their infants (Taylor et al., 2019).

(See: Gingrey, 2020; Hill et al., 2022; Hoyert, 2023; Population Reference Bureau, 2023; Taylor et al., 2019; Trost et al., 2022.)

Current Programs Addressing Structural Racism and Systemic Inequities in Health Care

Many health organizations are committed to addressing structural racism and systemic inequities in health care. While it is too early to know if these programs and organizations are making a difference, their efforts demonstrate movement and action in the right direction.

ADDRESSING SYSTEMIC RACISM

[Access multimedia content \(<https://openstax.org/books/population-health/pages/6-4-structural-racism-and-systemic-inequities-in-us-health-care>\)](https://openstax.org/books/population-health/pages/6-4-structural-racism-and-systemic-inequities-in-us-health-care)

This video from the Robert Wood Johnson Foundation highlights three communities for their work to dismantle structural racism to create fair opportunities for all.

Watch the video, and then respond to the following questions.

1. How does the sovereignty and advocacy mentioned in the Chickaloon Native Village segment in the video relate to the goals of population health?
2. In the Rocky Mount segment of the video, how do you think the community's efforts to remedy the effects of structural racism can benefit health outcomes in the community moving forward?
3. In the Worcester segment of the video, how do you think communication among representatives of different racial, ethnic, and socioeconomic groups can help the community address the social determinants of health?

Centers for Disease Control and Prevention

In its efforts to decrease and eventually eliminate racial health inequities, the CDC is working to address structural racism and the SDOH. Agencies across the CDC utilize scientific research, community programs, policy efforts, and workforce development (CDC, 2022a). Examples of the agencies' work include (CDC, 2022a):

- The CDC [Health Equity Glossary](https://openstax.org/r/chronicdisease) (<https://openstax.org/r/chronicdisease>) seeks to facilitate understanding and consensus around terminology utilized in health equity literature.
- The comprehensive [Health Equity Science and Intervention Strategy](https://openstax.org/r/core) (<https://openstax.org/r/core>) strives to ensure health equity is a fundamental part of the CDC's scientific portfolio with a health equity lens applied to program, intervention design, implementation, and evaluation.
- [Project REFOCUS](https://openstax.org/r/projectrefocus) (<https://openstax.org/r/projectrefocus>) (Racial Ethnic Framing of Community Informed and Unifying Surveillance) explores how to develop and expand public health surveillance to track how social stigma affects individuals.
- The SDOH Portfolio includes surveillance, research, policy, programs, partnerships, and communications to address health inequities and their intersection with the SDOH.
- The CDC's [Occupational Health Equity Program](https://openstax.org/r/niosh) (<https://openstax.org/r/niosh>) focuses on eliminating work-related inequities linked with social, economic, and environmental disadvantages.
- The [REACH](https://openstax.org/r/nccdp) (<https://openstax.org/r/nccdp>) (Racial and Ethnic Approaches to Community Health) Initiative focuses on reducing disparities for BIPOC communities with high rates of chronic diseases.
- The CDC's workforce efforts include implicit bias training, tracking and reporting workforce diversity data, and a diversity and inclusion steering committee.

American Medical Association

The AMA established the Center for Health Equity in 2019 to advance equity across all aspects of care. This effort includes a [health equity guide](https://openstax.org/r/ama) (<https://openstax.org/r/ama>) for physicians, nurses, and other health care professionals to provide guidance and promote a deeper understanding of equity-focused, person-first language (AMA, n.d.-a). The AMA also published its five-part strategic approach to advance health equity, a three-year roadmap that includes five strategic approaches. This roadmap aims to encourage action and accountability to embed racial justice in health care to advance health equity for all (AMA, n.d.-b). The five parts of the approach include (AMA, n.d.-b):

- embed equity in practice, process, action, innovation, and organizational performance and outcomes;
- build alliances and share power with meaningful engagement;
- ensure equity in innovation for marginalized and minoritized people and communities;
- push upstream to address all determinants of health; and
- foster truth, reconciliation, racial healing, and transformation.

National Institutes of Health

The NIH has acknowledged how historical racism has resulted in the marginalization and oppression of BIPOC communities, creating persistent health disparities, poor health status, and premature mortality among BIPOC communities (NIH, n.d.). The NIH recognizes that it is in a position of power to address structural racism by establishing policies, social norms, and practices that eliminate stereotypes and alleviate the ubiquitous effects of racism (NIH, n.d.). The NIH established the [UNITE initiative](https://openstax.org/r/nih) (<https://openstax.org/r/nih>) to promote racial equity and inclusion at the NIH and to address structural racism. The specific aims of the initiative are as follows (NIH, n.d.):

- U—understand people's experiences through listening and learning

- N—(engage in) new research on health disparities, minority health, and health equity
- I—improve the NIH culture and structure for equity, inclusion, and excellence
- T—(seek) transparency, communication, and accountability with all interested parties
- E—(engage in) extramural research to change policy, culture, and structure to promote workforce diversity

National Academy of Medicine

The NAM's [Culture of Health Program](https://openstax.org/r/culture) (<https://openstax.org/r/culture>) (CoHP), funded by the Robert Wood Johnson Foundation (RWJF), is a collaborative effort to identify strategies to create and maintain conditions that sustain equitable quality health for everyone (NAM, 2022). The program focuses on four approaches that scaffold and reinforce one another (NAM, 2022):

- Understand—building, informing, and elevating the evidence base to better understand and eliminate health inequities
- Translate—communicating the evidence in a timely and culturally congruent manner to bring understanding of the science to those working to advance health equity
- Engage—ensuring partners and interested parties working at every level to eliminate health inequities are given the tools they need to ensure effectiveness
- Learn—learning in real time from current activities to ensure effective evaluation and impactful metrics

The video [Building Equitable Communities](https://openstax.org/r/building) (<https://openstax.org/r/building>) from the RWJF highlights four communities for their work keeping community at the heart of community development, embracing what a culture of health means.

American Heart Association

The AHA's [call to action](https://openstax.org/r/ahajournals) (<https://openstax.org/r/ahajournals>) to address structural racism as a fundamental driver of health disparities outlines a plan for dismantling and addressing structural racism within the AHA (Churchwell et al., 2020). The AHA's strategies for addressing structural racism include five broad areas (Churchwell et al., 2020):

- Advocacy—advocacy and other externally facing efforts will adhere to antiracist principles such as advocating for affordable health insurance, including expansion of Medicaid in all states
- Quality improvement program—identify racist policies and practices within the AHA and provide consistent education and training of all staff on different manifestations of racism, ensuring accountability, diversity policies, and ensuring diversity of the AHA workforce
- Leadership—examine how to leverage its membership to ensure diversity, inclusion, health equity, and antiracism as essential elements coordinated with other AHA efforts
- Human resources/business operations—recruiting and supporting more early and midcareer investigators from historically marginalized groups
- Science—build an antiracist research agenda with input from key people focused on research that is directed at racism as a cause of poor cardiovascular and cerebrovascular health

Role of Nursing in Addressing Structural Racism and Systemic Inequities

Nursing is one of the largest, most trusted health care professions in the United States with nearly 5.2 million registered nurses (American Association of Colleges of Nursing [AACN], 2022; Gaines, 2023). Thus, nursing is well positioned to help address structural racism and systemic inequities. This role begins with conducting a critical evaluation of nursing education curricula, displaying a commitment to developing workforce diversity, speaking out against structural racism by naming it and discussing it, including the SDOH in all nursing assessments and plans, and engaging in advocacy for a more equitable health system.

Nursing Education

To address structural racism at the systems level requires a critical appraisal of the prelicensure nursing education curriculum. Nurse educators need to be aware of their hidden curriculum; knowingly or unknowingly, educators give certain content more weight and thereby reinforce the content as important. Academic nurse leaders, administrators, and nurse educators need to assess the curriculum to identify content that reinforces racism or discounts structural racism as an important factor in how nurses care for and treat their clients. Despite egalitarian faculty views, many faculty unknowingly commit curricular microaggressions, furthering a racist pedagogy (Ackerman-Barger et al, 2020; Emami & de Castro, 2021; Ochs, 2023). Microaggressions are common, everyday

slights, snubs, or insults directed toward minorities that may be intentional or not, but they communicate derogatory or negative messages to individuals based upon their minority group status (American Psychological Association [APA], 2019; NIH, 2016). An example is a person complimenting an Asian college student as surprisingly well-spoken ("You speak good English for an Asian") or mistaking a Black nurse for a service worker (APA, 2019; NIH, 2016). Educators must commit to an anti-racist pedagogy and educate students about their responsibility as nurses to engage in dismantling structural racism (Villarruel & Broome, 2020). This work includes updating the curriculum to include content on nursing care through the lens of structural racism, implicit bias, the SDOH, and health disparities.

Workforce Diversity

The nursing profession has given increased attention to diversity and inclusion to recruit and retain underrepresented students and faculty (Villarruel & Broome, 2020). A diverse nursing workforce is needed to better serve a diverse client population and make progress toward achieving health equity for several reasons. Nurses who are members of underrepresented minority groups are more likely to work in their communities and advocate for services and programs that are needed (AACN, 2023). They also improve communication and trust and bridge cultural and linguistic gaps among these underrepresented minority groups (AACN, 2023). By serving underrepresented communities, they may even improve access to health care among communities that have faced difficulties in accessing quality care (AACN, 2023). The National Center for Health Statistics names a lack of diversity in the health care workforce as a factor contributing to higher mortality rates among underrepresented minority groups (AACN, 2023). To increase diversity in the nursing workforce, it is important to remove historical obstacles to accessing health professions education among BIPOC communities and to advocate for and support the inclusion of more diverse health professions students (Dent et al., 2021). Recruiting more underrepresented nurses will not immediately address structural racism, but it will assist in efforts to reduce disparities and to achieve health equity (Villarruel & Broome, 2020). [Demographic Trends and Societal Changes](#) discusses this in more detail.

Naming Structural Racism

Naming structural racism as a social determinant of health highlights its significant impact on the overall health and well-being of BIPOC communities with broad implications for population health outcomes. Healthy People 2030 emphasizes health equity, recognizes SDOH as the key to achieving it, and calls out discrimination as a SDOH within the social and community context (ODPHP, 2020b). While this is an important step, nurses must use their collective voice and large numbers to lead the charge in educating others by naming structural racism as the fundamental driver of health disparities (CDC, 2021; Nardi et al., 2020; Williams et al., 2019). Nurses need to be able to talk about structural racism and link it to the persistence of White privilege, unconscious bias, and the power of the dominant culture. White privilege is not name calling or dismissing the lived experience of White individuals; rather, it is a recognition that structural racism has camouflaged societal advantages of being White due to the persistence of an inherently racially unequal society (Moorley et al., 2020).

HEALTHY PEOPLE 2030

Discrimination

Healthy People 2030 features many objectives related to the SDOH. [These objectives \(https://openstax.org/r/determinants\)](https://openstax.org/r/determinants) highlight the importance of "upstream" factors, conditions related to the economic, social, and physical environments, in promoting health equity, a state where everyone has a fair opportunity to attain their highest level of health. Discrimination is listed as a SDOH under the umbrella of the social and community context. The three objectives that could be related to structural racism, a form of discrimination, are as follows:

1. Increase the proportion of people whose water supply meets Safe Drinking Water Act regulations (EH-03)
2. Increase employment in working-age people (SDOH-02)
3. Reduce the proportion of children with a parent or guardian who has served time in jail (SDOH-05)

Include the Social Determinants of Health in All Nursing Assessments

Nurses are at the front line of client care. When completing admission assessments at the bedside, triaging a client in the emergency department or urgent care center, reviewing medical history in the outpatient clinic, providing health promotion education at the community center, visiting clients in their homes, screening children at the

schools, and advocating for public health services, nurses need to include a thorough assessment of the social determinants of health as these are directly related to structural racism. See [Social Determinants Affecting Health Outcomes](#). With client care, focusing solely on individual behaviors such as diet, exercise, smoking, alcohol, and drug use without including the context of the SDOH can further exacerbate structural racism (Scott et al., 2019). Substantial evidence exists that physical inactivity and poor nutrition are associated with experiences of discrimination (Selvarajah et al., 2022). Similarly, blaming clients for not seeking preventive care can be harmful as health insurance is not universally available to everyone due to many socioeconomic factors and past governmental health insurance injustices. With maternal–child health outcomes, “mother blame” is often included in the narrative of why Black women have worse outcomes than White women, sometimes related to individual behaviors or lack of preconception care, but this dismisses structural racism and the fact that Black women are most likely to be uninsured and less likely to have access to preconception care (Scott et al., 2019).

Advocacy

Nursing has been at the forefront of advocacy efforts since the beginning of the profession, but while there are examples of how nurses are addressing inequities in teaching, research, and practice, structural racism remains. Therefore, nursing needs to re-examine its advocacy efforts (Villarreal & Broome, 2020). Because race is an ascribed social category that results in inequality (ANA, 2022), nurses must extend advocacy beyond the individual client to address policy level issues. Nurse leaders have an ethical responsibility to address structural racism within the nursing profession and to be a part of the rebuilding of structures and systems that are anti-racist, address historical structural racism, and promote health equity (ANA, 2021).

Advocacy can take many forms, such as advocating for:

- professional development across health professions education on the role of structural racism and implicit bias in health care disparities;
- elimination of predatory advertising of alcohol, cigarettes, and vaping products among lower-income communities;
- accessible and high-quality care equally dispersed among zip codes;
- affordable health insurance for everyone, including Medicaid expansion in all states;
- equitable allocation of resources among zip codes;
- equitable models of care, prioritizing health over profits; and
- equal funding across all public-school districts to eliminate the disparities in resources that lower-income communities face.

Including a lens for structural racism when caring for clients and communities across the health care spectrum is an essential part of nursing. The nursing profession was founded on principles of social justice and health equity. Staying true to the professional and ethical mandate of nursing requires an understanding of structural racism and how the racist origins of our country are still impacting BIPOC communities today. Risk factors for ill health, such as sexual health behaviors, physical activity levels, nutrition, smoking cigarettes, and alcohol use, need to be viewed not only as causative agents contributing to poor health but also as a potential response to the chronic structural racism that has resulted in different opportunities in residence, education, employment, and health insurance (Selvarajah et al., 2022). Relative to privileged groups, groups exposed to racism and discrimination are more likely to struggle with poverty, neighborhood disinvestment, low educational attainment, lack of good employment prospects, and unhealthy environments. Racism drives these groups into these disadvantaged circumstances (Selvarajah et al., 2022). [Advocating for Population Health](#) discusses the nurse’s role as an advocate in more detail.

Chapter Summary

6.1 Understanding Different Forms of Racism

Structural racism is a deeply rooted, persistent, normative process of institutional policies, systems, laws, and practices that limit opportunities, resources, and the power of individuals based on race. It ensures differential access to quality education, housing, employment, and medical care. Forms of racism include personally mediated racism, internalized racism, eugenics, and scientific racism.

6.2 The Historical Context of Structural Racism in the United States

Structural racism in the United States can be traced back to British Colonial America, prior to the country's founding, with the ill treatment and forced removal of Native Americans from their lands and the terrible history of slavery. Though it has changed and evolved from the era of slavery and the Civil War, through Reconstruction and the Jim Crow era, in the internment of Japanese Americans and the boarding school policy for Native American and Alaskan children, in the redlining and racially restrictive covenants of the 1950s, the War on Crime and War on Drugs, and the current epidemic of police violence and unequal access to health care, structural racism has persisted.

6.3 Contemporary Structural Racism and Systemic Inequities in the United States

Despite some policies aimed at addressing structural racism and systemic inequities, their existence and effects remain. Differences in homeownership, home values, and credit scores by race persist in those areas that were formerly redlined. Many of these formerly redlined, majority-BIPOC neighborhoods also suffer environmental injustices as most of these redlined neighborhoods were in urban areas where there was

Key Terms

allostatic load (AL) the body's physiologic "wear and tear" due to an individual's exposure to stressors that accumulate throughout the lifespan

eugenics the erroneous theory that humans can be improved through selective breeding of populations

health equity a condition in which everyone has a fair opportunity to attain their highest level of health

internalized racism when members of a stigmatized race accept negative messages about their abilities and overall worth with self-devaluation, resignation, and hopelessness

Jim Crow era a period during which laws

widespread community disinvestment resulting in less green space, less tree canopies, and increased urban heat exposure. In addition, the Federal-Aid Highway Act built highways that cut through neighborhoods, disrupted green spaces, worsened air quality, increased pollutants, and sank property values. These environmental injustices are linked to adverse health outcomes such as asthma, adverse birth outcomes, and cancer.

6.4 Structural Racism and Systemic Inequities in U.S. Health Care

Structural racism and systemic inequities have many manifestations in health care. Racism and implicit bias, discriminatory policies in health insurance access and coverage, the effects of discriminatory mass incarceration, and the lasting impact from discriminatory policies in residential segregation all negatively impact health incomes for BIPOC populations. Residential segregation has lasting harmful effects on BIPOC communities, resulting in lower wealth accumulation, educational inequities driving employment disparities, the disproportionate burden of environmental hazards, and decreased access to quality foods and transportation. Structural racism intersects with health disparities and the social determinants of health, resulting in stark health inequities. The COVID-19 pandemic highlighted these existing inequities. The role of the nurse in addressing structural racism begins with conducting a critical evaluation of nursing education curricula, displaying a commitment to developing workforce diversity, speaking out against structural racism by naming it and discussing it, including the SDOH in all nursing assessments and plans, and advocating for a more equitable health system.

perpetuating institutional racism and the denial of Black Americans' constitutional rights were enforced across the southern United States, lasted from 1877 to about 1965

mass incarceration extreme rates of incarceration, particularly affecting large numbers of young Black men, in the U.S. prison system

occupational segregation the practice of separating workers by race into certain industries, resulting in a disproportionate representation of one race in a sector of the workforce

personally mediated racism prejudice and

discrimination where individuals or communities make assumptions about other individuals or communities based solely on race

racial profiling assuming or suspecting a person of criminal behavior based on race alone

racism the unfair treatment of individuals based on race

redlining the system of denying borrowers access to mortgage loans based on the location of properties in disadvantaged neighborhoods that were often comprised of minority populations

residential racial segregation the practice of keeping racial communities separate based on where people live

restrictive racial covenants racist restrictions that prevented Black individuals from homeownership through a legal agreement initiated by prior homeowners

scientific racism belief that White Europeans are superior to non-White people

structural racism a process resulting in a gap in access to societal opportunities based on race that results in institutional policies, systems, laws, and practices that limit opportunities, resources, and power

white flight the White American exodus from the cities to the suburbs, leaving BIPOC individuals behind, that occurred during the 1950s

Review Questions

1. After performing a community assessment, a nurse determines that a neighborhood with a higher concentration of BIPOC clients lacks access to medical care. Which term describes a major factor contributing to this finding?
 - a. Structural racism
 - b. Personally mediated racism
 - c. Internalized racism
 - d. Scientific racism

2. Which of these nurse actions would be considered an example of microaggression?
 - a. Asking a transgender client their pronouns
 - b. Telling an Asian client that they speak perfect English
 - c. Determining the dietary preferences of a Jewish client
 - d. Obtaining a medical interpreter for a client who does not speak English

3. Which of the following is an example of racial profiling?
 - a. Suspecting a person of criminal behavior based on race
 - b. Segregating communities based on race
 - c. Assuming all men of a certain racial group are dangerous
 - d. Community-wide disinvestment based on race

4. Which statement best highlights the continuing prevalence of racism in the U.S. health care system?
 - a. A university researcher has built a relationship with the local community.
 - b. Some states have attempted to impose work-reporting requirements as a means of restricting Medicaid expansion.
 - c. The city council is considering a summer jobs program for local teenagers.
 - d. The police department has established a community advisory board in each precinct.

5. Which client being seen in the community health clinic does the nurse anticipate is most affected by allostatic load?
 - a. A 52-year-old Native American construction worker with osteoarthritis of the knees
 - b. A 24-year-old Black man with persistent hypertension
 - c. A 62-year-old White woman with newly diagnosed hypothyroidism
 - d. A 38-year-old Hispanic woman concerned about a change in the color of a mole

6. Which environmental condition is a consequence of the redlining of neighborhoods that has negatively affected health outcomes of BIPOC individuals?
 - a. Decreased urban heat

- b. Less green space
 - c. Improved air quality
 - d. Increased access to clean water
- 7.** A public health nurse running a cost-free vaccination clinic for COVID-19 in an underserved community notes that the turnout is lower than expected. Which factor is the most likely explanation for the low turnout?
- a. Medicaid expansion
 - b. Low perceived personal risk for COVID
 - c. Lack of health insurance
 - d. Distrust of the health system
- 8.** A nurse is caring for four clients in the medical-surgical inpatient unit. One is a Black woman who has been admitted with pancreatitis, another is a White man who has been admitted with acute low back pain, the third is a Black man with pneumonia, and the fourth is a White woman who has been admitted with cholecystitis. The nurse mediates the Black woman with one oral Percocet tab for 8/10 pain, mediates the White man with two oxycodone tabs for 7/10 pain, does not mediate the Black man as he does not have current pain, and mediates the White woman with 2 mg of IV morphine for 8/10 pain. What is this an example of?
- a. Explicit racism
 - b. Implicit bias
 - c. Professional standard of care
 - d. Structural racism
- 9.** The community health nurse is working on creating nutrition initiatives for a community with a high incidence of heart disease and diabetes. Which of the following is a driving factor in the persistence of food deserts in areas of the United States?
- a. Structural racism
 - b. Implicit bias
 - c. Explicit racism
 - d. Mass incarceration
- 10.** Which of the following issues are implicated in the current maternal mortality public health crisis?
- a. Differences in health insurance coverage and access
 - b. Income level
 - c. Provider discrimination
 - d. Distrust in the medical system

CHAPTER 7

Policies and Regulatory Conditions Impacting Health Outcomes

FIGURE 7.1 Family Nurse Practitioner and Certified Diabetes Educator Carmen Morales-Board speaks about the impact of the Affordable Care Act. (credit: modification of work “Carmen Morales: Thank You Affordable Care Act” by Nancy Pelosi/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 7.1 Factors Affecting Public Health Policy
 - 7.2 Balancing Individual Rights and Public Health Interests
 - 7.3 Public Health Initiatives, Delivery Mechanisms, and Implications
 - 7.4 Policies Affecting Drug Approval, Supply, and Cost
-

INTRODUCTION As a pediatric nurse, Maria Sanchez spends a lot of her time making babies cry, but she knows she is doing so for a good cause. As a public health nurse, she provides routine vaccinations to children from birth through their teens, ensuring they are protected from preventable diseases like measles and polio. Sanchez has first-hand experience working within the context of **public health policy**—the laws, regulations, programs, behaviors, and decisions implemented within a society to promote public health.

Public health policy takes many forms, ranging from legislative policies to community outreach interventions, and it affects many fields, including health care, insurance, education, agriculture, and business, among others. Public health policy development and intervention occur at the local, state, national, and global levels:

- On a local level, a city council may develop policies to limit smoking on city properties.
- On a state level, a state legislature may pass emergency preparedness laws or regulations for its citizens.
- On a national level, the Centers for Disease Control and Prevention (CDC) provide policies to govern the administration of vaccinations in the United States; the U.S. Food and Drug Administration (FDA) develops policies related to the development and sale of food and drug items.

- On a global level, the World Health Organization (WHO) provides leadership on public health matters and establishes policies such as those related to controlling pandemics like COVID-19.

The most important focus of any public health policy is ensuring positive **health outcomes** for communities. Public health policy is essential to physical health outcomes and mental, social, and economic well-being.

This chapter provides an in-depth analysis of public health policies and regulations and their influence on the role of the community health/population health nurse and health outcomes for communities.

7.1 Factors Affecting Public Health Policy

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 7.1.1 Discuss factors affecting public health policy, including access, cost, and quality.
- 7.1.2 Describe the influence of payment models on health care access and quality of care.
- 7.1.3 Differentiate between the various health care delivery models.
- 7.1.4 Define care deserts and assess their implications on health outcomes.

This section discusses factors affecting public health policy, including access, cost, and quality; payment models; care delivery models; and the impact of health care deserts on health outcomes.

Access, Cost, and Quality

In the United States, access to health care factors into many public policy discussions and decisions. Most Americans access their health care through an employer's health insurance plan. In fact, employer-sponsored insurance in the United States covers 70 percent of workers, 36 percent of children, and 53 percent of nonworking adults (Commonwealth Fund, 2023). Although the country does not have a publicly funded **universal health care system**—a system that provides all people access to the full range of quality health services they need, when and where they need them, without financial hardship—the passage of the Patient Protection and Affordable Care Act (ACA) in 2010 led to millions of previously uninsured Americans receiving health care coverage (Congressional Budget Office, 2016). In addition, access to health insurance may be provided through Medicare—a government health insurance program established in 1965 that covers millions of Americans aged 65 and older and some others with disabilities, end-stage renal disease, and amyotrophic lateral sclerosis (ALS) (Medicare.gov, n.d.). Another health care access vehicle for some Americans is Medicaid, a national health insurance plan that covers some low-income families and children and individuals with disabilities. Established in 1965, Medicaid was expanded with the passage of the ACA, but because it is state-managed, its eligibility requirements and benefits differ from state to state (Centers for Medicare and Medicaid Services [CMS], 2023).

Access to health care is also impacted by technology. During the COVID-19 pandemic, **telehealth**, or telemedicine—delivering health care services through technology—increased dramatically ([Figure 7.2](#)). Although the use of technology to provide health care services was an essential step in providing health care at the time, its continued use poses questions about its quality and whether telehealth appointments are accessible to everyone (U.S. Government Accountability Office, 2022).

Health care cost is another factor that plays a role in public health policy discussions and decisions. The United States has one of the world's highest costs of health care. In fact, in 2021, U.S. health care spending totaled \$4.3 trillion (roughly equivalent to \$12,914 per person) (CMS, 2022). This is about twice as much as the average cost of health care per person in other developed countries.

FIGURE 7.2 A nurse specialist with the Naval Medical Center San Diego's Joint Tele-Critical Care Network provides support to a remote intensive care unit via teleconference. (credit: Luke Cunningham/U.S. Navy/Flickr, Public Domain)

The high spending rate per person has not led to higher health care quality in the United States. A 2021 Commonwealth Fund report ranked the United States last among 11 high-income countries on:

- access to care, with the United States ranking last on factors such as health care affordability and timeliness
- health care efficiency, with the United States trailing other countries in terms of simplifying insurance, billing, and payment
- equity, with the United States ranking lowest in terms of disparities in health care experiences between lower- and higher-income groups
- health care outcomes, with the United States performing worst on outcomes such as infant mortality rate and life expectancy

How can the United States lower its health care expenditures while also increasing access to health care, health care efficiency, and equity? Policy changes are one way the United States can effect more positive outcomes. This section discusses some factors that affect health care policy, including containing costs through evolving payment models, improving client care using various client care models, and avoiding barriers to health care such as those found in health care deserts.

Payment Models

The quality of health care provided to clients in the United States depends in part on how health care professionals are allowed to administer and bill for their services. As noted earlier, despite having the highest per capita expenditure on health care across high-income countries, the United States has no universal health care system and a low quality of care. Public health policies that relate to **payment models**—the mechanisms by which health care services are established and paid for—may help to address this issue.

Currently, the health care system is transitioning from the traditional fee-for-service model—providers and organizations are reimbursed based upon the volume of services they provide—to payment based upon the value of those services, which includes value-based care and alternative payment models (American Hospital Association, 2023). The American Medical Association (2022) describes the most common payment models for physicians. It divides them into three categories: core payment models, supplementary payment models, and organizational models. [Table 7.1](#) summarizes each type.

Core Payment Models (can exist alone without other payment types)	
Bundled payments (episode-based payments)	Physician practices receive payment based on episodes of client care according to a defined set of diagnoses and services provided to the client over a specific period. This model allows practices and health systems to achieve higher revenue by avoiding client complications, discount negotiation, and choosing a client care setting, which leads to lower costs.
Capitation	Physician practices receive payment to manage the client's health condition per client per period, which is usually 1 month. The health plan applies rules that govern which clients are included within the physician practice.
Fee-for-service	Physician practices are paid a flat rate for each client visit, test, or procedure performed. Through this payment model, practices can achieve higher revenue with more clients and procedures each day. However, physicians may not cover their costs using this model.
Supplementary Payment Models (cannot exist on their own; must coexist with one or more of the core payment models)	
Pay for performance	The payer pays physicians according to prescribed practice performance on defined metrics (e.g., blood pressure levels, blood glucose, hospital admissions, emergency room visits, etc.), based on the quality of care and/or utilization of care services. Providers may receive an incentive for meeting prescribed performance metric goals through pay for performance.
Retainer-based payment	Physician practices or other organizations receive capitation payments from the client. These payments, also known as "concierge" payments, are usually paid per client per year or month as a membership fee that covers an array of services.
Shared savings programs	Physicians or health care practices receive payment throughout the contract year instead of a capitation of payments during or before the year. Total costs for a specific client population are compared with a cost target which can lead to a lump-sum payment incentive or penalty for not meeting prescribed goals.
Organizational Models (combined payment models that create additional payment models)	
Accountable care organizations (ACOs)	Large health systems where an individual physician practice or a collection of physicians enter into a contract with a payer, typically under a fee-for-service payment model, to provide care to a population of clients. This network is responsible for improving health outcomes and reducing spending for a particular client population. Organizations may include physician groups, health systems, hospitals, and behavioral health organizations.
Medical homes	An integrated team of health care providers such as nurses, physicians, and care managers provides care that addresses the "whole person." Organizations can become recognized as accredited "Patient-Centered Medical Homes" through the National Committee for Quality Assurance (NCQA). The main source of revenue for most practices is fee-for-service payments; they may also receive additional payments in enhanced fee-for-service payment rates, per-month patient care management fees, and pay-for-performance payments for high performance on measures of quality, client experience, or cost.

TABLE 7.1 Physician Payment Models

Like physicians, health care organizations are reimbursed in different ways, including prospective payment systems, bundled payments, and Accountable Care Organizations (American Hospital Association [AHA], 2023). Recently, value-based purchasing programs have significantly changed hospitals' approach to providing care. For example, the Hospital Value-Based Purchasing Program bases Medicare payments on the quality of care rather than the services performed. Hospitals with higher rates of post-operative infections, ventilator-associated pneumonia, and

other negative outcomes associated with hospital care receive decreased reimbursement. Accordingly, hospitals are incentivized to focus on health care quality. Another example of a reimbursement structure designed to increase the providers' quality of care is the Hospital Readmissions Reduction Program. This program, administered through the CMS, penalizes hospitals with higher-than-expected levels of readmissions.

This complex framework of health care reimbursement influences how and where care is provided to clients and by whom (National Academies of Sciences, Engineering, and Medicine [NASEM] et al., 2021a). Accordingly, payment systems can affect nurses' ability to address a community's health needs. For example, the traditional fee-for-service payment system that focuses on physician reimbursement does not recognize the value of care provided by other health care team members, including nurses (NASEM et al., 2021a). This limits the ability of the health care system to address the social determinants of health (SDOH). It is currently unclear which newer payment model(s) will prevail and become dominant. However, nurses have the opportunity to make a more measurable impact in the newer reimbursement models. For example, nurses working as case managers and care coordinators can help manage a population's health and reduce costs associated with chronic illness (NASEM et al., 2021a). Overall, community nurses will be better able to promote continuity of care between the health systems and clients at home.

Care Delivery Models

The payment models previously described are the foundation for delivering care. **Care delivery models** refer to how health care providers work together to provide health care to clients. One example of a care delivery model is the collaborative care model, which "seeks to impact the clinical outcomes of patients who present with depression in primary care" (Collaborative Family Healthcare Association, 2023). Through this model, a psychiatrist and care manager are members of an interdisciplinary care team that manages a group of clients who have been screened for depression and need a higher level of intervention to achieve positive health outcomes. In addition to addressing the clients' behavioral and psychological needs, the team addresses physical needs, such as the maintenance of chronic diseases (e.g., diabetes, hypertension, cancer, and heart disease). Through this model, health care team members collaborate to achieve the common goal of ensuring the best possible health outcomes for clients.

According to the AHA (2019a), to achieve better outcomes for clients, hospitals and health systems across the United States have had to redesign how they provide client care. The AHA identifies four care models as the most common in the United States: accountable care organizations and medical homes, previously defined in [Table 7.2](#), integrated service lines, and provider-sponsored health plans.

With **integrated service lines**, hospitals and health care systems organize around specific disease states such as cancer, heart disease, and diabetes throughout the continuum of client care. This model contrasts the traditional care provision, where service lines based on disease state are siloed. In **provider-sponsored health plans**, plans are either sponsored or acquired by hospitals, physician groups, or health systems, which take over responsibility for the total cost of care for the clients enrolled in the health plan. These organizations may often take on financial risks of providing care for the clients enrolled in the health plan.

[Table 7.2](#) provides examples of these four care delivery models. The type of care model health care professionals choose to provide care is in part determined by health care policy and, in part, determines health care policies based on the revenues and outcomes it achieves.

Care Delivery Model	Example and Key Results
Accountable care organizations	Caravan Health partners with rural and independent health systems to ensure positive client outcomes. This has led to 60 percent or higher cost savings and improved quality scores.
Integrated service lines	New York's Mount Sinai Health System utilizes a care guide that visits clients in the hospital and coordinates client care transition to home, post-hospital follow-up, and transportation as needed for appointments. This has resulted in emergency room utilization dropping from 26 percent to 3 percent.

TABLE 7.2 Care Delivery Models and Examples (See AHA, 2019a.)

Care Delivery Model	Example and Key Results
Medical homes	Ohio's Summa Health provides care to clients through an integrated, team-based approach where primary care is the focus. Every aspect of the client's health, including physical and social issues, is addressed. This has led to lower hospital readmission rates. Today, 77 percent of Summa Health's primary care practices are accredited as Patient-Centered Medical Homes.
Provider-sponsored health plans	Sharp HealthCare in San Diego County, California, offers a care management program across the entire client care continuum. The Sharp health plan is the highest-rated organization of its kind in the state of California.

TABLE 7.2 Care Delivery Models and Examples (See AHA, 2019a.)

Care Deserts

Care deserts (or **medical deserts**) are areas where individuals have limited access to health care services such as hospitals or health clinics (Nguyen & Kim, 2021). Care deserts are most often found in rural areas and in tribal communities and can take many forms, including limited to no access to maternal health services—**maternal care deserts**—or limited to no access to pharmacy services—**pharmacy deserts**. More than 80 percent of counties in the United States lack proper access to needed medical services (Nguyen & Kim, 2021). Almost 50 million Americans are more than 60 minutes from a level I and II trauma center (Soto et al., 2018). It is estimated that over one-third of the U.S. population lives in counties that lack sufficient health care infrastructure to ensure good health outcomes. This may include a lack of access to services, medications, primary care providers, hospitals, and community health centers (Nguyen & Kim, 2021). For example, 136 rural hospitals closed between 2010 and 2021; 19 went out of business in 2020, the highest number since 2005 (AHA, 2022). Although this number dropped dramatically in 2021—when only two rural hospitals closed—the improvement may be attributed to federal relief funds associated with the COVID-19 pandemic that have now ended (Levinson et al., 2023). While fewer urban hospitals have closed over the past decade, those that do close tend to be in lower-income communities and treat clients who are uninsured or covered by Medicaid (KFF, 2020b). Closures of hospitals have compound effects because they are sometimes the only form of care to which local residents have access ([Figure 7.3](#)) (AHA, 2019b).

FIGURE 7.3 U.S. Department of Agriculture (USDA) Deputy Secretary Jewel Bronaugh speaks during the groundbreaking for the construction of a new rural hospital funded through the USDA. (credit: Lance Cheung/USDA/Flickr, Public Domain)

A care desert may be created for various reasons. One contributing factor is demographic shifts. Over the past decades, many rural areas in the United States have experienced a sharp decrease in their overall population. Such shifts lead to declines in revenue for health care providers like hospitals and health clinics. Because of this,

organizations may choose to leave less populated areas for more populated ones. Health care providers also have little motivation to offer care in neighborhoods where many people are uninsured or underinsured or covered through Medicare and Medicaid. Medicaid reimburses health care providers at a lower rate than private insurance companies such as Blue Cross Blue Shield (KFF, 2020a). As such, there is often a hesitancy to offer care in areas with a high rate of Medicaid-eligible individuals.

MEDICAID ISSUES FORCING ILLINOIS DOCTOR OFFICES TO CLOSE, CREATING 'MEDICAL DESERTS'

[Access multimedia content \(<https://openstax.org/books/population-health/pages/7-1-factors-affecting-public-health-policy>\)](https://openstax.org/books/population-health/pages/7-1-factors-affecting-public-health-policy)

This news video from Illinois reports on how health care professionals and physicians working in underserved communities face an uncertain future related to challenges receiving Medicaid reimbursement.

Watch the video, and then respond to the following questions.

1. How many clients rely on Medicaid, according to the video?
2. How many Medicaid claims are denied as compared with claims from private insurance?
3. Why are doctors who accept clients who use Medicaid losing money?
4. How are difficulties with Medicaid contributing to medical deserts?

Communities that lack high-quality schools or work opportunities for spouses of medical professionals may find it difficult to recruit health care providers such as primary care and specialty care providers (Association of American Medical Colleges, 2023; Health Resources and Services Administration [HRSA], 2023). Research shows that although 20 percent of the U.S. population lives in rural areas, fewer than 10 percent of U.S. doctors practice in rural communities (Joynt et al., 2016). This exacerbates care deserts.

Lack of access to health care in such care deserts leads to many negative health outcomes, including untreated health problems and chronic diseases such as diabetes and hypertension. Communities with less access to primary care struggle with disease diagnosis and prevention, client education, and treating acute and chronic illnesses. Lack of health care access especially affects communities of color (Alfred, 2022).

Finally, clients who must travel long distances to secure care lose valuable work time and incur costs related to travel. In contrast to urban areas, rural regions frequently lack public transportation services. Older adult clients often have chronic conditions, the management of which may necessitate frequent medical appointments (Rural Health Information Hub [RHIhub], 2022). When rural hospitals close, employment opportunities in the community decrease, as the hospital may be one of the main employers in that community, and local economies suffer through revenue loss and tax base loss (AHA, 2019b; Harsha, 2022).

As discussed in [Demographic Trends and Societal Changes](#), care deserts are often addressed using technology such as telemedicine. Because the health care provider (e.g., physician, nurse practitioner, or other specialist) can provide care to individuals remotely, clients in care deserts can receive routine health care (RHIhub, 2021). However, in many areas, clients are still left without access to emergency, inpatient, and surgical care. Many also lack access to simple urgent care for conditions like acute pharyngitis because group A *Streptococcus* (group A strep) tests must currently be done in person, not via telehealth. Finally, in-person primary care visits for screenings like skin cancer are still preferred to telehealth until the technology improves.

The government offers some care options to those living in care deserts through Federally Qualified Health Centers (FQHCs). These federally funded nonprofit health centers or clinics serve “medically underserved” areas and populations throughout the United States. FQHCs provide primary care services to all individuals, even those not able to pay, on a sliding scale basis (HealthCare.gov, n.d.).

WHAT IS AN FQHC?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/7-1-factors-affecting-public-health-policy>\)](https://openstax.org/books/population-health/pages/7-1-factors-affecting-public-health-policy)

This video provides an overview of FQHCs, also known as community health centers.

Watch the video, and then respond to the following questions.

1. What types of care do FQHCs provide to the communities they serve?
2. Who is eligible to seek care at an FQHC?

One organization seeking to address physician shortages in health care deserts is the National Health Services Corps, which is operated by the Health Resources and Services Administration (HRSA) arm of the U.S. Department of Health and Human Services (HHS). This organization connects underserved rural, urban, and tribal communities with health care providers. The organization's 20,000 members currently provide care to over 21 million people in the United States in over 9,000 community health care sites (HRSA, 2023). The organization offers loan repayment and scholarships to its member health care practitioners, making practicing in underserved areas more appealing.

In its report [*Nowhere to Go: Maternity Care Deserts Across the U.S. 2022 Report*](https://openstax.org/r/marchofdimesa) (<https://openstax.org/r/marchofdimesa>), the March of Dimes recommends several policy solutions to federal and state governments to reduce maternity care deserts (March of Dimes, 2022). Recommended solutions include passing a Medicaid postpartum extension from 60 days to 12 months, expanding telehealth services to bridge gaps in health care, and strengthening network requirements for health care plans made available through the ACA (March of Dimes, 2022).

According to the National Academies of Sciences, Engineering, and Medicine (NASEM, 2021b), nurses play a significant role in addressing health inequities such as the lack of qualified health care professionals and the lack of access to health services available to populations. The NASEM (2021b) points to the profession's deep roots in community health advocacy and social justice, which refers to seeking to ensure equal access to health care services for everyone within a society. The NASEM identifies five key roles to improve health equity for populations: awareness, adjustment, assistance, alignment, and advocacy (NASEM, 2021b). Let's briefly discuss each.

- With awareness, the nurse seeks to identify and understand social risks and opportunities for a select population. For example, the nurse would inquire about the availability of quality housing and health care services for the population.
- Adjustment has to do with incorporating activities that seek to accommodate populations to address identified barriers, such as providing care through telehealth for individuals lacking adequate transportation.
- Assistance refers to actions the nurse takes to connect populations with various resources such as providing transportation vouchers to ensure individuals have a means by which to get to and from appointments.
- Alignment refers to the actions of the nurse or a health care system to understand the needs of a community or population and implement mechanisms to address health inequities such as investing in ridesharing or time-bank programs, which are geared at increasing access to health care services.
- Advocacy has to do with partnerships between organizations to promote policies that create and deploy programming to address health inequities within communities, such as improving infrastructure that improves transportation for individuals with limited transportation to and from health care services.

Since its inception, the nursing profession has been heavily involved in ensuring everyone has equal access to resources. As such, the community health nurse and the advanced practice nurse are key partners in minimizing health inequities within communities (NASEM, 2021b).

7.2 Balancing Individual Rights and Public Health Interests

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 7.2.1 Discuss health as a human right.
- 7.2.2 Examine the implications of failing to protect the right to health.
- 7.2.3 Describe government obligations to protect the right to health.
- 7.2.4 Explain international and other mechanisms to protect the right to health.
- 7.2.5 Summarize the tensions between individual rights and public health.

Whether health care is a human right has long been debated. The WHO's constitution states, "health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition" (2023a, para 2). Accordingly, WHO (2022) has asserted that governments are responsible for ensuring access to quality, affordable health care for their citizens. Unlike many other countries, the United States does not

include a right to health or health care in its constitution (Jost, 2023). Nevertheless, the federal government has supported health care over the years by implementing Medicare, Medicaid, and federal tax subsidies for employer-sponsored health care (Jost, 2023). Despite these programs, health care costs have increased, leaving more Americans uninsured. For example, by 2010, more than 46.5 million nonelderly Americans were uninsured (Tolbert et al., 2022). In 2010, Congress passed, and President Obama signed into law, the ACA. Although this act did not recognize health care as a basic human right, it did bring the country closer to providing federal assistance for those who need health care (Jost, 2023).

HUMAN RIGHTS 101 | EPISODE 8: WHAT IS THE RIGHT TO HEALTH?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/7-2-balancing-individual-rights-and-public-health-interests>\)](https://openstax.org/books/population-health/pages/7-2-balancing-individual-rights-and-public-health-interests)

This video discusses health as a human right.

Watch the video, and then respond to the following questions.

1. What does the right to health mean?
2. What are two ways to ensure our right to health?
3. What is your obligation as a nurse to ensure your clients' right to health?

Implications of Failing to Protect the Right to Health

Violations of health as a human right have serious consequences for individuals and populations. Discrimination, both overt and implicit, in delivering health care services creates barriers to positive health outcomes. Health as a human right is especially relevant as it relates to underrepresented populations (WHO, 2022). Underrepresented individuals tend to face higher rates of diseases such as cancer, cardiovascular disease, and chronic respiratory diseases and tend to have higher rates of mortality (deaths associated with a particular disease). Additionally, underrepresented populations may be impacted by laws and policies that further marginalize them, thus making it harder to access health care treatment, prevention, care services, and rehabilitation (WHO, 2022). **Marginalized communities** are those communities that are excluded from the dominant group's cultural, economic, educational, or social life (Weitzman Institute, 2023). A community or population can be marginalized based on race, age, gender identity, sexual orientation, religion, physical ability, language, immigration status, or another factor.

Ideally, health policies and programs address such health disparities. Healthy People 2030 defines **health disparities** as health differences linked to social, economic, and/or environmental disadvantages (Office of Disease Prevention and Health Promotion [ODPHP], n.d.-a). These health inequalities are systematic differences in health that exist between people of different socioeconomic levels, social classes, genders, ethnicities, sexual orientations, or other social groups (Eikemo & Oversveen, 2019). Racial and ethnic disparities in health outcomes persist in the United States. Some examples related to health care access include the following (Radley et al., 2021):

- Black, Latino/Hispanic, and American Indian and Alaska Native (AIAN) individuals are less likely to have health insurance and are more likely to encounter cost-related barriers to accessing health care.
- Medicare beneficiaries who are Black are more likely than beneficiaries who are White to seek care in an emergency department for conditions typically managed through primary care.
- Black, Latino/Hispanic, and AIAN adults are less likely than Asian American, Native Hawaiian, and Pacific Islander (AANHPI) and White adults to receive an annual flu shot.

One purpose of health policies is to mitigate health inequalities by improving systems through which health care services are provided. For example, to address hunger, the Supplemental Nutrition Assistance Program (SNAP), formerly known as the food stamp program, ensures certain low-income individuals have access to nutritious food, which improves an array of outcomes for adults and children (USDA, 2023).

Health policy should also make it feasible for individuals with long-term health conditions to access the necessary care. Inadequate health care both contributes to and exacerbates poor health outcomes. For example, ideally, community health nurses who work with clients with diabetes would assess their needs holistically and manage their care with a team of health professionals—including a primary care provider, a podiatrist, and an endocrinologist—and oversee the client's daily and long-term needs. In addition, nurses would coordinate other

services for clients who need them, such as consultations and treatment by ophthalmologists, certified diabetes care and education specialists, and mental health professionals (American Diabetes Association, n.d.). However, clients who lack access to this type of disease management because they are not insured or have other socioeconomic factors that limit their ability to participate are more likely to experience poor health outcomes, such as kidney failure, blindness, and amputation.

Government Obligations to Protect the Right to Health

The United States does not expressly acknowledge the rights of its citizens to receive health care—it is the only developed nation without access to universal health care (Harvard Public Health, 2023). Despite this, the United States has developed infrastructure and implemented policies and programs designed to support health care for all Americans. Federal agencies such as the CDC and the HHS work to improve the population's health. The CDC's mission is to protect Americans from health, safety, and security threats. The CDC protects the nation's health security through research, health information dissemination, and other programs that support communities to do the same (CDC, 2022a). The HHS works to enhance the population's health and well-being through effective services and the support of scientific advancements in medicine, public health, and social services (HHS, n.d.). Healthy People 2030, a data-driven initiative, includes health policy as a focus area and has set the goal of using health policy to prevent disease and improve health (ODPHP, n.d.-a, n.d.-b).

Mechanisms to Protect the Right to Health

According to the WHO (2022), to protect the right to health is to abide by the Core Components of the Right to Health, outlined in Article 12 of the Covenant on Economic, Social, and Cultural Rights. The Core Components of the Right to Health as defined by the WHO (2022) are shown in [Table 7.3](#) and include availability, accessibility, acceptability, and quality.

Core Component	Description
Availability	Requires that sufficient functioning health care facilities and programs are available to all. Availability should be measurable by proven metrics across all segments of society to diagnose and remedy health coverage and health workforce gaps.
Accessibility	Requires that health care facilities and programs be accessible to all. Accessibility has four overlapping dimensions: non-discrimination, physical, economic, and information. An analysis of barriers—geographic, physical, legal, and economic, among others—is needed to account for gaps in coverage but also to understand how these barriers impact health outcomes, especially to the most vulnerable populations. Establishing laws and policies, as well as comprehensive monitoring systems, will help mitigate gaps and promote accessibility to all populations.
Acceptability	Requires policies and ethics sensitive to gender. Health facilities and programs should be people-centered and provide services tailored to the needs of diverse population groups in accordance with accepted international standards of confidentiality and informed consent.
Quality	Requires that all health care facilities and programs be scientifically and medically approved. Quality health services for all is the goal, which means they should be safe, effective, people-centered, timely, equitable, integrated, and efficient.

TABLE 7.3 Core Components of the Right to Health as Defined by the WHO (See WHO, 2022.)

The year 2018 marked the 70th anniversary of the birth of human rights law through the Universal Declaration of Human Rights as well as the birth of the governance of global health through the WHO (Meier et al., 2018). Since their adoption, these laws and policies have provided the foundation for public health (Meier et al., 2018). Scholars, health care advocates, providers, and others must join forces with human rights in public health policies, programs, and practices to ensure health is maintained as a human right.

To accomplish this, the American Public Health Association (APHA) established a new Human Rights Forum, which seeks to build the capacity of professionals operating in the public health space to more effectively bring human rights into public health practices (Meier et al., 2018). The APHA's mission is to improve public health and achieve equity in health status (APHA, 2023). APHA's Center for Public Health Policy works to promote inclusion of

evidence-based practices into policies that address SDOH. They work with all levels of government to influence policy and strengthen local health departments. The APHA has achieved many notable contributions to public policy since its creation in 1872. [Table 7.4](#) provides several examples of specific public health policies and organizations responsible for them.

Policy Type	Organization	Policy Example
Smoking restriction	Local city government	The Town of Arlington, Massachusetts (n.d.), has passed many bylaws related to smoking restrictions in its buildings.
Food safety	FDA	The FDA Food Safety Modernization Act (FSMA) provides a set of rules to prevent food safety problems, to detect and respond to food safety problems, and to improve the safety of imported food (FDA, 2020).
Sexually transmitted diseases (e.g., syphilis, AIDS, chlamydia)	CDC	The CDC's Community Approaches to Reducing Sexually Transmitted Diseases (CARS) initiative enables "community engagement methods and partnerships to build local STD prevention and control capacity" (CDC, 2020a).
COVID-19	WHO	In 2022/23, WHO updated its COVID-19 Global Preparedness, Readiness, and Response Plan to assist global efforts to reduce the disease's spread and prevent, diagnose, and treat it. To meet these goals, WHO produced eight policy briefs that guide policymakers (WHO, 2023b).

TABLE 7.4 Examples of Public Health Policies

Public health nurses are a key part of the APHA's efforts to influence public policy. The APHA partners with other community nursing organizations including the Alliance of Nurses for Healthy Environments, the Association of Community Health Nursing Educators, the Association of Public Health Nurses, the National Association of School Nurses, and the Rural Nurse Organization to form the Council of Public Health Nursing Organizations to advocate for health in all policies (2023).

State policies influence health as well. The Association of State and Territorial Health Officials (ASTHO), a nonprofit representing public health agencies in the United States, tracks policy trends that impact state and territorial health departments. They recently released their list of top state public health policy issues to watch in 2023 (ASTHO, 2022). The ASTHO list includes the following existing and emerging policy trends:

- immunization
- reproductive health
- overdose prevention
- public health agency workforce and authority
- mental health
- data privacy and modernization
- health equity
- HIV
- environmental health
- tobacco and nicotine products

Tensions Between Individual Rights and Public Health

Although the WHO and the UN have declared health to be a human right, tensions between individual rights and public health persist in the United States, with its individualistic cultural emphasis. Tobacco restrictions, seat belt use, helmet use, and mandated vaccinations have brought forth such tensions for decades. For example, in the United States, cigarette smoking remains the leading cause of preventable disease, disability, and death (CDC, 2023a). The percentage of adults who smoke has declined from 20.9 percent in 2005 to 11.5 percent in 2021 (CDC, 2023a). Public health interventions that have contributed to this decline include smoke-free policies, tobacco price increases, and health education campaigns (ODPHP, n.d.-d). Those who support reducing and eliminating cigarette smoking assert that it impedes the population's right to live a healthy life. Opponents of these efforts believe that it is the tobacco products—not the people—who are to blame, arguing that safer smoking products should be

developed to allow people who smoke to continue to do so but with fewer negative health effects. Currently, 29 states and the District of Columbia still have laws that recognize smokers as a protected class of workers that cannot be discriminated against (American Lung Association, 2023).

The COVID-19 pandemic exacerbated tensions between individual rights and public health (The Network for Public Health Law [TNPHL], 2021). To protect the public from contracting COVID-19, federal, state, and local governments enacted policies such as mandatory business closures, mask mandates, social distancing, and vaccination mandates (Figure 7.4). These policies sparked public debate, with some viewing them as infringing upon individual freedoms. Although the policies may seem to be infringements on individual rights, they are considered constitutional because they were put in place to protect the public (TNPHL, 2021).

FIGURE 7.4 During the COVID-19 pandemic, the CDC recommended wearing masks in public to slow the spread of infection. However, the federal government did not issue a mandate requiring them, leaving the decision up to state and county governments. Requirements for masking, therefore, varied widely. (credit: modification of work "Trader Joe's: Please wear a mask Covid-19 sign" by G. Edward Johnson/Wikimedia Commons, CC BY 4.0)

How are such decisions made? According to university professor Lawrence O. Gostin, Director of the O'Neill Institute for National & Global Health Law at Georgetown University, four standards must be in place if such restrictions are to be implemented (Gostin, 2005):

- There must be a necessity for government action.
- The action must employ reasonable means.
- The action must be proportional.
- The action should avoid harm to the health of the individual.

The following must also be considered when developing interventions to address a public health issue (Hadler et al., 2018):

- Once an acute public health problem is identified, intervention must occur as soon as possible to minimize preventable death and disease.
- Public interventions must be based on science and evidence-based practice. Public fear and politics must be carefully navigated to build trust within communities.
- Intervention must be specific to a particular community and will depend on the nature of the problem, its cause, mode of spread, and other key factors.
- Open two-way communication between all parties involved must occur.

MANY AMERICANS HATE WEARING MASKS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/7-2-balancing-individual-rights-and-public-health-interests>\)](https://openstax.org/books/population-health/pages/7-2-balancing-individual-rights-and-public-health-interests)

This video discusses the conflict between mask mandates and the rights of citizens within a society.

Watch the video, and then respond to the following questions.

1. Are mask mandates violating one's rights? Why or why not?
2. What can be done to mitigate the tension between opponents and proponents of mask mandates?
3. As a nurse, what is your role in upholding public health policy?

7.3 Public Health Initiatives, Delivery Mechanisms, and Implications

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 7.3.1 Describe Healthy People 2030, a public health initiative that seeks to improve health outcomes.
- 7.3.2 Categorize public health policies by mechanisms of delivery (fiscal policy, regulation, education, preventative treatment, and screening).
- 7.3.3 Examine the implications of the Institute for Healthcare Improvement (IHI) Triple Aim to improve population health, reduce costs, and improve client satisfaction.

This chapter has discussed health policy and the balance between the right to human health and individual rights. This section will look at one U.S. public health initiative, the mechanisms of public health delivery, and a framework that has been developed to improve population health, reduce costs, and improve client satisfaction.

Healthy People 2030

[The Health of the Population](#) described **Healthy People**, a public health initiative that seeks to improve health outcomes in the United States. Put forth by the HHS, the 10-year plan establishes public health priorities and data-driven objectives to improve public health and well-being over a decade. The most recent iteration of the plan, Healthy People 2030, includes 23 high-priority **leading health indicators** (LHIs) to improve health and well-being over the lifespan. Most LHIs address factors that affect major causes of death and disease, such as the proportion of people with access to health insurance and the number of people exposed to unhealthy air (ODPHP, n.d.-c).

Public health policies and programs are what drive and establish the mechanisms by which such health outcomes are achieved. [Table 7.5](#) provides examples of LHI objectives as established by Healthy People 2030 and examples of policies and programs necessary to achieve them.

Leading Health Indicator Objective	Public Health Policy or Program to Achieve the Objective
Increase the proportion of people with health insurance	The passage of the ACA improved access to health insurance through the expansion of Medicaid and the health care marketplace. The HHS (2022) reports that the total enrollment for Medicaid expansion, Marketplace coverage, and the Basic Health Program reached a high of over 35 million people as of early 2022.
Increase the proportion of persons who know their HIV status	According to the CDC, increasing the number of people who are aware of their HIV status is critical to preventing HIV infections. To increase Americans' awareness of their HIV status, the CDC has established the Expanded Testing Initiative, through which three programs have been launched (see Expanded Testing Initiative (https://openstax.org/r/cdcgovhiv)) (CDC, 2020b).

TABLE 7.5 Examples of LHIs and Associated Public Health Policies or Programs

Leading Health Indicator Objective	Public Health Policy or Program to Achieve the Objective
Reduce household food insecurity and, in doing so, reduce hunger	<p>The Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) provides federal grants to states for “supplemental foods, health care referrals, and nutrition education for low-income pregnant, breastfeeding, and non-breastfeeding postpartum women, and to infants and children up to age 5 who are found to be at nutritional risk” (USDA Food and Nutrition Service, n.d.)</p> <p>In a 2015 policy statement, the American Academy of Pediatrics (AAP) recommended that “pediatricians engage in efforts to mitigate food insecurity at the practice level and beyond,” including connecting families to and advocating for federal nutrition programs (AAP, 2015).</p>
Increase the proportion of persons who are vaccinated annually against seasonal influenza	<p>State laws establish requirements regarding the vaccination of schoolchildren (CDC, 2016). In addition, the CDC works with public health agencies and private organizations to “improve and sustain immunization coverage and to monitor the safety of vaccines” (CDC, 2022c).</p>
Reduce drug overdose deaths	<p>The Overdose Response Strategy (ORS) is a collaboration between the CDC and the High Intensity Drug Trafficking Areas (HIDTA) program designed to help communities reduce drug overdoses through evidence-based intervention strategies at the local, regional, and state levels (CDC, 2023b).</p> <p>The Bureau of Justice Assistance’s Comprehensive Opioid, Stimulant, and Substance Abuse Program (BJA COSSAP) supports state, local, and tribal responses to substance use to decrease overdose deaths, improve public safety, and improve access to treatment services in the criminal justice system (CDC, 2023b).</p>
Reduce the number of days people are exposed to unhealthy air	<p>The U.S. Environmental Protection Agency (EPA) Clean Air Act programs have lowered the levels of six common pollutants by 78 percent and have led to an improvement in air quality in the United States (EPA, 2023).</p>

TABLE 7.5 Examples of LHIs and Associated Public Health Policies or Programs

Public Health Policy Delivery Mechanisms

Health policy interventions are how health policies are carried out (Hadler et al., 2018). Public health officials responsible for making decisions must consider certain factors, including selecting the appropriate intervention, facilitating the implementation of the intervention, and assessing the effectiveness of the intervention. Mechanisms for delivering public health policy interventions include fiscal policy, regulation, education, preventative treatment, and screening. [Table 7.6](#) defines public health policy delivery mechanisms and provides examples of each.

Category	Explanation	Example(s)
Fiscal Policy	The U.S. government can use fiscal policy, including subsidies, free services, and taxes, to incentivize healthy behaviors and discourage unhealthy ones (Nugent & Knaul, 2006).	<ul style="list-style-type: none"> Medicaid is an example of a subsidized program that provides health-promoting services for free or reduced rates. During the COVID-19 pandemic, the government provided free COVID test kits to American households to help stop the spread of the disease. Alcohol and cigarette taxes are examples of fiscal policy measures that disincentivize unhealthy activities.
Regulation	Any law, ordinance, rule, and so on issued by a government agency or organization.	The FDA is the U.S. agency responsible for regulating food- and health-related products. For example, under the Federal Food, Drug, and Cosmetic Act (FFDCA), the FDA regulates the safety and effectiveness of medical devices.
Education	The information, tools, and resources needed to obtain and sustain positive health outcomes (also referred to as health literacy).	The CDC's Diabetes Self-Management Education and Support (DSMES) Toolkit program provides individuals living with diabetes the necessary education and support to make the best health care decisions, leading to more positive health outcomes (CDC, 2022b).
Preventative Treatment	Routine care that people receive to maintain their health or prevent disease.	Well-child visits, vaccinations, and blood tests as required by the Children's Health Insurance Program (CHIP) are examples of preventative treatment.
Screening	Tests that screen people for diseases or other issues, often catching them before symptoms are noticed.	CDC guidelines on disease-specific screenings, such as mammograms, colonoscopies, and blood pressure screenings, are examples of screenings to improve public health by preventing disease progression.

TABLE 7.6 Public Health Policy Delivery Mechanisms

HEALTHY PEOPLE 2030

Education Access and Quality

Education is a crucial social determinant of health. [Access to education \(https://openstax.org/r/healthypeopleba\)](https://openstax.org/r/healthypeopleba) increases the probability that individuals will have the necessary skills to make the best decisions related to their health. Education also assists in increasing one's health literacy, which is the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.

Institute for Healthcare Improvement Triple Aim

Despite its high costs, the U.S. health care system lags in factors relating to access, affordability, and quality. As discussed in [What Is Population Health?](#) the **Triple Aim** is a framework developed by the Institute for Healthcare Improvement (IHI) that aims to improve health care system performance on three levels (IHI, 2023):

- Improving the client experience of care (including quality and satisfaction)
- Improving the health of populations
- Reducing the per capita cost of health care

The IHI Triple Aim recommends a change process that includes identifying target populations; defining systems, aims, and measures to target the population; developing a portfolio of project work that is strong enough to drive system changes; and performing rapid testing that is specific to the needs of the local communities and the issues the community faces (IHI, 2023). The key to the success of the IHI Triple Aim is the utilization of and adherence to

five components, shown in [Table 7.7](#).

Component	Explanation/Examples
Focus on Individuals and Families	<ul style="list-style-type: none"> For medically and socially complex clients, establish partnerships among individuals, families, and caregivers, including identifying and supporting a family member or friend to coordinate services for the client among multiple care providers. Jointly plan and customize care at the level of the individual. Actively learn from the client and family to inform work for the greater population. Enable individuals and families to better manage their own health.
Redesign of Primary Care Services and Structures	<ul style="list-style-type: none"> Have a team for basic services that can deliver at least 70 percent of the necessary medical and health-related social services to the population. Deliberately build an access platform for maximum flexibility to provide customized health care for the needs of clients, families, and providers. Cooperate and coordinate with other specialties, hospitals, and community services related to health.
Population Health Management (Prevention and Health Promotion)	<ul style="list-style-type: none"> Work with the community to advocate and provide incentives for smoking prevention, healthy eating, exercise, and reduction of substance misuse. Develop multi-sector partnerships, utilize key partner resources, and align policies to provide community-based support for all who wish to make health-related behavioral changes. Integrate health care and publicly available community-level data utilizing GIS mapping to understand local context to determine where and from whom health-related strategic community-level prevention, health promotion, and disease-management support interventions would be most useful.
Cost Control Platform	<ul style="list-style-type: none"> Achieve less than 3 percent yearly for per capita cost by developing cooperative relationships with physician groups and other health care organizations committed to reducing the waste of health care resources. Achieve lowest decile performance in the Dartmouth Atlas measures by breaking or countering incentives for supply-driven care. Reward health care providers, hospitals, and health care systems for their contribution to producing better health for the population and not just producing more health care. Orient care over time—the “patient journey”—targeted to the best feasible outcomes.
System Integration and Execution	<ul style="list-style-type: none"> Match capacity and demand for health care and social services across suppliers. Ensure that strategic planning and execution with all suppliers, including hospitals and physician practices, are informed by the population’s needs. Develop a system for continued learning and improvement. Institute a sustainable governance and financial structure for the Triple Aim system. Efficiently customize services based on appropriate segmentation of the population. Use predictive models and health risk assessments that consider situational factors, medical history, and prior resource utilization to deploy resources to high-risk individuals. Set and execute strategic initiatives to reduce inequitable variation in outcomes or undesirable variation in clinical practice.

TABLE 7.7 Five Components of the IHI Triple Aim (See IHI, 2009, 2023.)

The results and benefits of the IHI Triple Aim are as follows (IHI, 2023):

- Populations are healthier.
- Clients receive more coordinated care, which lessens the burden of disease and illness.
- The per capita cost of care for populations is stabilized.

- The burden on publicly funded health care budgets (such as Medicaid and Medicare) is lessened.
- The economic well-being of populations is improved.

Organizations and programs such as primary care coalitions, regional health care systems, and others have experienced success implementing the IHI Triple Aim (IHI, 2023).

Since the inception of the Triple Aim in 2008, two more aims have been proposed, including a **Quintuple Aim** (Mate, 2022). Those two aims are improving workforce well-being and safety and advancing health equity.

THEORY IN ACTION

The Story of New Ulm—A Population Health Transformation

[Access multimedia content \(<https://openstax.org/books/population-health/pages/7-3-public-health-initiatives-delivery-mechanisms-and-implications>\)](https://openstax.org/books/population-health/pages/7-3-public-health-initiatives-delivery-mechanisms-and-implications)

This video describes a population health initiative in Minnesota that focuses on improving the health, well-being, and quality of life of the residents. Note this video is over 22 minutes.

Watch the video, and then respond to the following questions.

1. How does the Heart of New Ulm study use electronic health records and data warehousing to meet clients' needs?
2. What are examples of health interventions at a population level?
3. How does the Triple Aim relate to the Heart of New Ulm?
4. Do you agree that improving health outcomes requires making it easy for clients to do the right thing? Why or why not?

7.4 Policies Affecting Drug Approval, Supply, and Cost

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 7.4.1 Examine the role of the FDA in protecting public health.
- 7.4.2 Understand the global drug manufacturing supply chain.
- 7.4.3 Examine factors contributing to U.S. pharmaceutical costs being higher than those of other countries and their implications.

As discussed, the FDA is a regulatory body under the HHS umbrella. The FDA has broad regulatory authority and is responsible for protecting public health by ensuring the safety and efficacy of the food supply and all medical drugs, products, and devices (FDA, 2023). [Table 7.8](#) lists examples of products over which the FDA has authority in eight regulatory areas.

Regulatory Areas	Products over Which the FDA Has Authority
Foods	<ul style="list-style-type: none"> • Bottled water • Dietary supplements • Food additives • Foods such as meats, poultry, and egg products, which are also regulated by the USDA • Infant formulas
Drugs	<ul style="list-style-type: none"> • Prescription and nonprescription drugs
Biologics	<ul style="list-style-type: none"> • Allergenics • Blood and blood products • Cellular and gene therapy products • Tissue and tissue products • Vaccines for humans

TABLE 7.8 The FDA's Regulatory Areas and Products over Which It Has Authority

Regulatory Areas	Products over Which the FDA Has Authority
Medical devices	<ul style="list-style-type: none"> • Dental devices • Heart pacemakers • Surgical implants and prosthetics • Tongue depressors and bedpans
Electronic radiation products	<ul style="list-style-type: none"> • Laser products • Mercury vapor lamps • Microwave ovens • Sunlamps • Ultrasonic therapy equipment • X-ray equipment
Cosmetics	<ul style="list-style-type: none"> • Color additives found in makeup • Nail polish and perfume • Skin moisturizers and cleansers
Veterinary products	<ul style="list-style-type: none"> • Livestock feeds • Pet foods • Veterinary drugs and devices
Tobacco products	<ul style="list-style-type: none"> • Cigarettes/cigarette tobacco • Cigars • Electronic cigarettes • Hookah • Smokeless tobacco

TABLE 7.8 The FDA's Regulatory Areas and Products over Which It Has Authority

As a regulatory body, the FDA has specific policies and regulations aimed at protecting the health and well-being of the American public. The agency develops rules and regulations based on evidence-based processes and through the input of other government agencies and subject matter experts. The FDA regulations are then published in the [Federal Register](https://openstax.org/r/federalregister) (<https://openstax.org/r/federalregister>), the U.S. government's official publication for notifying the public of agency actions. FDA regulations are either required or authorized by statute.

The rules established by the FDA may come through the creation of laws by Congress, presidential executive orders, or regulations established within the FDA. Before a new drug is approved for public consumption, for example, the drug is subject to a stringent testing and research process to identify potential harm to the affected population. Once the food, drug, or other item is approved, it is then made available for public consumption.

One of the most recent FDA actions was the approval of the COVID-19 vaccine (FDA, n.d.). Although the process of approving a drug or other material for human and animal consumption generally takes years, the approval of the COVID-19 vaccine was expedited due to the nature of the COVID-19 pandemic and the need to limit new cases of the disease (FDA, n.d.). The FDA and drug makers worked at an accelerated pace to complete the required testing on the new vaccines before they were released to the public to ensure their safety and efficacy ([Figure 7.5](#)).

FIGURE 7.5 During the COVID-19 pandemic, a national initiative called Operation Warp Speed accelerated the development, production, and distribution of COVID-19 vaccines. In the photo, a phlebotomist assistant draws a client's blood for a preliminary, baseline antibody test for the Phase III trial of AstraZeneca's coronavirus (COVID-19) vaccine. (credit: "NMCSD NBHC Kearny Mesa COVID-19 Vaccine Trial" by Jake Greenberg/U.S. Navy/Flickr, Public Domain)

5 THINGS YOU NEED TO KNOW ABOUT THE DRUG APPROVAL PROCESS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/7-4-policies-affecting-drug-approval-supply-and-cost>\)](https://openstax.org/books/population-health/pages/7-4-policies-affecting-drug-approval-supply-and-cost)

This video provides a brief overview of the process the FDA follows to approve new drugs.

Watch this video, and then respond to the following questions.

1. What considerations are involved in the decision to test a new drug on human subjects?
2. What are the three phases of clinical trials?

The Global Drug Manufacturing Supply Chain

One factor affecting the supply and cost of pharmaceutical drugs is the global drug manufacturing supply chain. A **supply chain** consists of the participants at each step in the process that takes a product from raw materials to finished goods sold to customers. As it relates to global drug manufacturing, the supply chain refers to the movement of the various components and materials essential to providing a drug for human consumption.

The pharmaceutical supply chain is a global, complex system. The key role players include raw material suppliers, drug manufacturers, regulatory agencies, wholesale distributors, pharmacies, pharmacy benefit managers (PBMs), health care providers, and clients (Kaylor, 2023). First, raw materials are sourced and transported for manufacturing. Pharmaceutical manufacturing in the United States has declined significantly, and up to 90 percent of needed raw materials are estimated to come from other countries (Constantino, 2021). Next, the drugs are transferred to wholesale distributors, who provide them to the pharmacies. Pharmacy benefit management companies are the intermediaries working with insurers, employers, and government programs to negotiate the prices the clients will pay for the prescriptions (Kaylor, 2023).

The supply chain's quality and safety are essential to the United States' national security and public health (Costantino, 2021). Standards related to the global drug manufacturing supply chain assist governments and drug manufacturers in increasing the availability of safe, quality medicines that are necessary to build client and health provider trust (U.S. Pharmacopeial Convention [USPC], 2023). Examples of standards include the processes employed by organizations, such as the FDA, before medications, foods, and other materials are deemed safe for

human and animal consumption. These guidelines are necessary to promote a strong and resilient supply chain so that people have the drugs they need at the time they need them. It is imperative that such regulations are backed by science, producing high-quality development and manufacturing processes and high-quality drugs for human consumption (USPC, 2023).

The pharmaceutical supply chain faces several challenges, including supply chain visibility and rising prescription drug costs (Kaylor, 2023). These challenges became evident during the COVID-19 pandemic by negatively affecting the pharmaceutical supply chain in several ways (Choe et al., 2020):

- They prompted unexpected increases in demand for critical medications needed to treat clients with COVID-19.
- They disrupted critical medication production as supplies of these medications were rapidly depleted while manufacturers were unable to keep up with the demand.
- They delayed regulatory oversight of production as travel restrictions curtailed FDA officials' ability to inspect manufacturing facilities.
- They interrupted global trade of medications as many countries limited their pharmaceutical exports to meet the increased demand in their own countries.
- They revealed a limited understanding of local and demand-driven shortages that are not always reflected in the current FDA database of drug shortages.
- They highlighted inadequacies in supply chain planning and management. The United States has limited ability to coordinate and share medications and instead must rely upon pharmaceutical wholesalers.

The recently established Supply Chain Disruption Task Force is working to address the supply chain issues by developing a series of recommendations for supply chain diversification (Edwards, 2021). In the interim, the United States is working to overhaul its strategic national stockpile program. The stockpile program was established to disperse medications around the country in the event of a short-term disaster or biological attack (Edwards, 2021). The United States is redesigning the program to incorporate a strategic stockpile of drug ingredients so that domestic manufacturers can quickly produce needed medications in the event of an emergency.

Pharmaceutical Costs

Americans spend more on prescription medications than citizens of other countries. A recent study determined that U.S. prescription drug prices were 2.56 times those in 32 comparable countries (Bosworth et al., 2022). Accordingly, pharmaceuticals are one of the fastest-growing components of health care spending in the United States (Ellis, 2019). In July 2022, the average price increase per drug was almost \$250, an increase of 7.8 percent (Bosworth et al., 2022). That same year, the list prices of several drugs increased by more than \$20,000 or 500 percent (Bosworth et al., 2022). Rising prescription drug costs are an issue for many Americans.

There are several reasons for the high drug costs (Rajkumar, 2020):

- **Monopolies:** Newer drugs do not yet have any alternatives or competition in the form of generic medications or comparable versions from other companies. Also, some established drugs are manufactured by a limited number of companies, decreasing competition.
- **Disease severity:** Clients with serious illnesses are usually willing to pay any price for a drug that can save or prolong their life.
- **Research and development:** Developing a new drug is a lengthy, costly process. It takes approximately 12 years and \$3 billion dollars for a new drug to get approved; only 10 to 20 percent of drugs developed and tested make it to the market.
- **Political power of the pharmaceutical industry:** Although the federal government is aware of the need to address high drug prices, the pharmaceutical industry is an influential lobbyist that frequently limits the government's attempts to enact change.

The increase in drug costs disproportionately impacts underrepresented and marginalized populations. As drug costs continue to rise, access to drugs will become even more problematic for these populations. Drug adherence may decline as individuals and families make difficult choices related to priorities such as choosing to pay for housing and food or for pharmaceuticals to treat disease (Ellis, 2019). This leads to continued health disparities.

State and national policymakers are exploring options to better control and lower drug costs. In 2022, Congress

passed the Inflation Reduction Act to address high and rising drug prices (Bosworth et al., 2022). The law requires drug manufacturers to pay rebates to Medicare if the drug prices for Medicare beneficiaries exceed inflation.

Community health nurses must recognize the impact of high drug prices on their clients. When assessing a client's medication history, nurses should determine if the client is adhering to the prescribed regime. If not, nurses should examine the client holistically to determine the cause. Clients may not take their medications as prescribed if they cannot afford them. Nurses should work with clients to identify programs that can help them pay for prescriptions. Alternatively, nurses could work with the prescribers to identify less costly alternatives for the client.

CASE REFLECTION

Working with Clients Who May Have Difficulty Affording Prescribed Medications

Read the scenario, and then respond to the questions that follow.

A client with a diagnosis of diabetes, hypertension, and congestive heart failure visits her local primary care physician for a six-week follow-up appointment after being discharged from the hospital with an exacerbation of her congestive heart failure. The client presents with shortness of breath, and her blood pressure is 190/100. The client did not bring her medications to her doctor's visit as her discharge nurse instructed. She reports that she has been taking her medications as scheduled. The client is currently unemployed and has applied for Medicaid benefits.

1. How should the nurse approach obtaining a more detailed medication history from the client?
 2. If the client indicates she is not taking her medications because she cannot afford them, what next step(s) should the nurse take?
-

Chapter Summary

7.1 Factors Affecting Public Health Policy

Public health policy refers to the laws, regulations, programs, behaviors, and decisions implemented in a society to promote public health. There is a direct correlation from access to health care, the cost of health care, and the quality of health care to health outcomes. High health care costs impact an individual's ability to access health care services. Different payment models and care delivery models affect the quality of care. When individuals cannot access health care services, health outcomes, including maintenance of chronic disease processes, are compromised.

7.2 Balancing Individual Rights and Public Health Interests

Although the U.S. Constitution does not include a right to health or health care, the federal government supports health care through Medicare, Medicaid, federal tax subsidies for employer-sponsored health care, and agencies such as the CDC and the HHS that work to improve the population's health. Violations of health as a human right have serious consequences for individuals and populations. Discrimination in delivering health care services creates barriers to positive health outcomes, and underrepresented individuals tend to face higher rates of chronic diseases. Health policies can improve the systems through which health care services are provided and make it feasible for individuals with chronic health conditions to access necessary care. Public health nurses are integral to the APHA's efforts to influence public policy. The tension between individual rights and

Key Terms

accountable care organizations (ACOs) payment model in large health systems where individual physician practices or a collection of physician practices contract with a payer, typically under a fee-for-service payment model, to provide care to a population

bundled payments payment model in which physician practices receive payment based on episodes of client care according to a defined set of diagnoses and services provided to the client over a specific period; also known as episode-based payments

capitation payment model in which physician practices receive payment per client per period, which is usually 1 month; health plan rules govern which clients are included in the physician practice

public health continues to be salient in the United States; this was especially apparent during the COVID-19 pandemic.

7.3 Public Health Initiatives, Delivery Mechanisms, and Implications

Healthy People is a public health initiative that seeks to improve health outcomes in the United States. This 10-year HHS plan establishes public health priorities and data-driven objectives to improve public health and well-being over a decade. Healthy People 2030 includes 23 high-priority LHIIs to improve health and well-being over the lifespan. Mechanisms for the delivery of public health policy interventions include fiscal policy, regulation, education, preventative treatment, and screening. The IHI Triple Aim is a framework to improve health care system performance on three levels (improving the client experience, improving population health, and reducing costs).

7.4 Policies Affecting Drug Approval, Supply, and Cost

The FDA has broad regulatory authority and is responsible for protecting public health by ensuring the safety and efficacy of the food supply and all medical drugs, products, and devices. The global drug manufacturing supply chain affects the supply and cost of pharmaceutical drugs. Pharmaceuticals are one of the fastest-growing components of health care spending in the United States. The increase in drug costs impacts underrepresented and marginalized populations the most.

care delivery models delivery strategies that prescribe the specific ways in which professionals work together to provide health care services

care deserts areas in the United States where individuals have limited access to health care services such as hospitals or health clinics; also called medical deserts

episode-based payments payment model in which physician practices receive payment based on episodes of client care according to a defined set of diagnoses and services provided to the client over a specific period; also known as bundled payments

fee-for-service payment model in which physician practices are paid a flat rate for each client visit, test, or procedure performed; through this model, practices can achieve higher revenue with more

clients and procedures each day	services
health disparities systematic differences in health that exist between socioeconomic positions, social classes, genders, ethnicities, sexual orientations, or other social groups with differentiated access to material and non-material resources	payment models mechanism by which health care services are established and paid for
health literacy the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions	pharmacy deserts areas in the United States where individuals have limited to no access to pharmacy services
health outcomes the results of a health intervention	provider-sponsored health plans health plans that are either sponsored or acquired by hospitals, physician groups, or health systems that assume responsibility for the total cost of care for clients enrolled in the health plan
Healthy People a 10-year HHS plan that establishes public health priorities and data-driven objectives to improve public health and well-being over a decade	public health policy laws, regulations, programs, behaviors, and decisions implemented in a society to promote public health
integrated service lines hospitals and health systems organize around specific disease states such as cancer, heart disease, and diabetes throughout the continuum of client care	Quintuple Aim a proposed update to the Institute for Healthcare Improvement's Triple Aim
leading health indicators (LHIs) small subset of high-priority Healthy People 2030 objectives selected to drive action toward improving health and well-being	retainer-based payment payment model in which physician practices or other organizations receive capitation payments from the client; also known as "concierge" payments
marginalized communities communities excluded from the dominant group's cultural, economic, educational, or social life	shared savings programs payment model in which physicians or health care practices receive payment throughout the contract year; total costs of care for a specific client population are compared with a cost target at the end of year, which can lead to a lump-sum payment incentive or penalty for not meeting prescribed goals
maternal care deserts areas within the United States where individuals have limited to no access to maternal care services	supply chain participants at each step in the process that takes a product from raw materials to a finished good that is sold to customers
medical deserts areas within the United States where individuals have limited access to health care services such as hospitals or health clinics; also called care deserts	telehealth the provision of health care using technology, including the internet, computers, tablets, and smartphones
medical homes care delivery model in which an integrated team of health care providers such as nurses, physicians, and care managers provides care that addresses the "whole person"	Triple Aim a framework developed by the Institute for Healthcare Improvement that describes an approach to optimizing health system performance
pay for performance payment model in which physicians are paid according to prescribed practice performance on defined metrics, which are based upon the quality of care and/or utilization of care	universal health care system a system in which all people have access to the full range of quality health services they need, when and where they need them, without financial hardship

Review Questions

1. A community health nurse is working at a community event to help individuals obtain health insurance. For which individual would the nurse most likely recommend Medicare?
 - a. A 62-year-old client with heart failure
 - b. A 54-year-old client who is employed
 - c. A 28-year-old client with two children and no income
 - d. A healthy retired 67-year-old client

2. An older adult client has developed a pressure injury while in the hospital for the treatment of pneumonia. The nurse understands that the development of the pressure ulcer will affect Medicare reimbursement for this client in what way?
 - a. There will be no reimbursement for this client's hospital stay.

- b. Reimbursement will be increased due to the development of complications.
 - c. Reimbursement will be reduced as a result of the development of a pressure injury.
 - d. There will be no change in reimbursement.
3. The nurse is discussing homecare instructions with a client who was treated on a medical unit for an exacerbation of heart failure. The client tells the nurse that follow-up care will be difficult since they live 30 miles away and do not drive. Which intervention by the nurse can best meet the immediate needs of this client for follow-up care?
- a. Meeting with community leaders about the need for medical facilities in the rural community
 - b. Providing the client with agencies that may be able to assist with transportation
 - c. Arranging for home monitoring and telehealth follow-up
 - d. Reinforce that follow-up is important and that the client needs to find rides to appointments
4. A nurse works at a clinic that provides care to clients through all stages of heart failure and coordinates transitions of care. Which care delivery model is the clinic using to provide care to clients?
- a. Collaborative care
 - b. Integrated service line
 - c. Provider-sponsored health plan
 - d. Medical home
5. A community health nurse provides health care to a marginalized community. Which factor will guide the nurse's health programming?
- a. Most members of this community are eligible for Medicaid.
 - b. Community members are likely to seek preventative health care.
 - c. Barriers to accessing health care may be present.
 - d. Laws and policies protect the health of this community.
6. Which concept concerning LHIs will the nurse use to develop programs to improve health outcomes in the community?
- a. LHIs are primarily aimed at reducing childhood illnesses.
 - b. LHIs should be included in the plan of care for every individual.
 - c. LHIs improve health and well-being across the lifespan.
 - d. LHIs provide standardized guidelines for caring for certain diseases.
7. Which action can the community health nurse take to help an unemployed client without health insurance mitigate the high cost of prescription drugs?
- a. Assist the client to reduce the amount spent on food and other items.
 - b. Ask the client which medications they feel are not necessary.
 - c. Speak with the provider about lower-cost alternatives.
 - d. Explain that all medications must be taken to improve health outcomes.
8. Which category of public health policy is the nurse engaged in while performing lipid profile testing at a community health fair?
- a. Regulation
 - b. Screening
 - c. Education
 - d. Preventative treatment
9. A client in a community health center is receiving team-based care for primary care needs and management of heart failure. When the nurse assesses that the client is missing appointments due to difficulties with transportation, the nurse refers the client to the team social worker. Which care delivery model is this client experiencing?
- a. Accountable care organization

- b. Integrated service line
 - c. Medical home
 - d. Provider-sponsored health plan
- 10.** Which component of the IHI Triple Aim is the nurse performing when working with the community to develop programs to reduce teenage smoking?
- a. System Integration and Execution
 - b. Population Health Management
 - c. Redesign of Primary Care Services and Structures
 - d. Cost Control and Platform

CHAPTER 8

Social Determinants Affecting Health Outcomes

FIGURE 8.1 In some impoverished neighborhoods, the only operating businesses sell mainly soda, candy, and cigarettes. (credit: modification of work "No Loitering" by Paul Sableman/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 8.1 Economic Stability
- 8.2 Neighborhood and Built Environment
- 8.3 Educational Environment, Access, and Quality
- 8.4 Social and Community Context
- 8.5 The Cumulative Effect of Inequalities on Health

INTRODUCTION In the United States, clinical care accounts for only 20 percent of a person's health outcomes (Whitman et al., 2022). The remaining 80 percent are attributed to social and economic factors, health behaviors, and the physical environment. This means that 80 percent of health outcomes relate to one's income, education level, employment, neighborhood environment, and health behaviors. Putting it plainly, a person's zip code is a better predictor of their overall health than their genetic code.

Healthy People 2030 defines the **social determinants of health** (SDOH) as “the conditions in the environments where people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks” (Office of Disease Prevention and Health Promotion [ODPHP], 2020v, para. 1). They are the nonmedical factors that impact health outcomes (CDC, 2022b). Healthy People 2030 groups the SDOH into five domains: economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context ([Figure 8.2](#)). They are called *social determinants* of health because they operate outside of nonmodifiable (unchangeable) biological and genetic factors; instead, they are

determined by social status. The SDOH have a major effect on an individual's health and well-being. Examples include access to safe housing, exposure to discrimination or violence, income level, and language and literacy skills (ODPHP, 2020v).

The good news is that factors affecting these SDOH are modifiable (changeable), and health care professionals, including nurses, are at the forefront of driving positive changes in health outcomes for populations. The [Future of Nursing 2020-2030 report](https://openstax.org/r/namedupublications) (<https://openstax.org/r/namedupublications>) highlights **health equity** as a major focus for nursing and states that achieving health equity begins with assessing the SDOH in every client encounter (Wakefield et al., 2021). The Centers for Disease Control and Prevention defines health equity as a “state in which everyone has a fair and just opportunity to attain their highest level of health” (CDC, 2022g, para. 1; MISPH, 2020). Addressing the SDOH is a key task of the professional nurse, as nursing practice is founded on the principle of **social justice**, the view that each individual deserves equal rights and opportunities (American Public Health Association, 2022). By incorporating assessments of the SDOH and their intersection with health outcomes, the nurse can drive positive change and support upstream interventions at the community, local, and state levels.

This chapter will follow the Healthy People 2030 outline on each of the SDOH and define what each determinant means. It will explore how each determinant correlates with health outcomes and why it is imperative for community and public health nurses to address the SDOH in practice and to advocate for social justice and change.

 **HEALTHY PEOPLE 2030**

Social Determinants of Health

Healthy People 2030 features many objectives related to the SDOH. [These objectives](https://openstax.org/r/healthypeoplepriority) (<https://openstax.org/r/healthypeoplepriority>) highlight the importance of “upstream” factors, conditions related to the economic, social, and physical environments, in promoting health and reducing **health disparities**. Health disparities are the *preventable* differences in health between groups of individuals, usually as a result of social or economic factors, geographic location, or environment. See [Health Disparities](#) for more information on this topic.

8.1 Economic Stability

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 8.1.1 Discuss the relationship between poverty and economic insecurity.
- 8.1.2 Describe the impact of employment on economic stability.
- 8.1.3 Explain how housing instability contributes to economic insecurity.
- 8.1.4 Describe the link between a person's socioeconomic position and their health.

Economic stability in the context of the SDOH refers to the ability to access necessary resources and care to promote healthy living. It requires having a steady source of income with stable employment that is safe from occupational-related health risks. The necessary resources include the ability to afford quality housing in a safe neighborhood with access to clean air and water, transportation, and healthy food options.

In the context of an individual or a family, **economic stability** refers to a situation where the individual has a steady source of income and regular access to resources that are essential for a healthy life, such as food, clothing, housing, transportation, child care, and health insurance. A consistent income is one key to economic stability at the individual and family levels. Individuals with steady employment are less likely to experience economic insecurity (ODPHP, 2020a).

Consistently earning a **living wage** is another critical component of economic stability that directly correlates with what an individual can afford to live a healthy life. A living wage is one that affords a modest standard of living for the individual and family (Global Living Wage Coalition, 2018). The federal minimum wage is far below what is generally considered necessary for a family to survive; that is, it is less than a living wage (Glasmeier, 2023). The federal minimum wage rate has not kept pace with inflation and other cost-of-living adjustments that disproportionately impact Black, Indigenous, and people of color (BIPOC) individuals (Khan & Khattar, 2022). The last update to the federal minimum wage occurred in 2009, when it was increased to \$7.25 per hour. Twenty states currently use the federal minimum wage. The ability to afford housing, food, child care, transportation, and health insurance affects an individual's economic or financial stability (ODPHP, 2020a; Rural Health Information Hub [RHIhub], 2020a). A goal of Healthy People 2030 is to "help people earn steady incomes that allow them to meet their health needs" (ODPHP, 2020a, para. 1).

Poverty

Economic insecurity is when an individual or family cannot consistently afford housing, food, clothing, transportation, child care, or health care. Economic insecurity is directly linked to **poverty**, a state in which an individual lacks a socially acceptable amount of money or possessions (Merriam-Webster, 2023). In 2021, almost 38 million individuals, close to 12 percent of the population, lived in poverty in the United States (Creamer et al., 2022). Individuals and families living in poverty cannot afford the resources essential to living a healthy life (ODPHP, 2020a). Economic insecurity is also associated with unemployment, underemployment (willing but unable to find full-time work), and low-wage employment. Many individuals with stable work still do not earn enough income to afford the resources necessary for good health (ODPHP, 2020a). Almost one in every three individuals in the United States is considered economically insecure, with incomes below 200 percent of the federal poverty level (Langston, 2018). The groups most affected are BIPOC communities, which comprise slightly more than half of the individuals who are economically insecure (Langston, 2018).

The **socioeconomic gradient** is another term for the relationship between income and health, namely, the association between low **socioeconomic position** (SEP) and increased disease risk and premature death (Bonaccio, et al., 2020). SEP refers to one's position in society based on social and economic factors of income, education, and employment. Individuals living with economic insecurity often cannot access resources that support healthy and quality living. These resources, along with economic stability, are what comprise the SDOH: stable housing, safe neighborhoods, access to healthy and affordable foods, and access to quality education. Living with economic insecurity makes it difficult to attain and sustain the determinants of health, thereby perpetuating a cycle of poverty, economic and housing instability, food insecurity, and a lack of access to educational and employment opportunities. This contributes further to income inequality and insecurity and results in a multitude of negative health outcomes (ODPHP, 2020b).

The U.S. Census Bureau (USCB) determines poverty levels by using a set of income thresholds that vary by family composition. If a family's total income is less than the set family threshold, that family and each individual in it are considered to be living in poverty (USCB, 2023). The official poverty definition uses income before taxes and does not include noncash benefits such as public housing, food stamps, tax credits, and Medicaid benefits (USCB, 2023). In 2021, the federal designation of poverty for an individual was an income under \$12,880 per year, and for a household (family of four) it was an income under \$26,500 per year (ODPHP, 2020b). According to the U.S. Department of Housing and Urban Development (USHUD), regardless of the location, a family of four with one adult employed full-time at the federal minimum wage rate is unable to afford fair-market rent for a two-bedroom apartment (Habitat for Humanity, 2023). Families who live in poverty cannot consistently afford quality housing, food, health care, and other necessities.

Poverty is cyclical and often persists for long periods of time. Research supports the concept of **generational poverty**, the phenomenon of persistent poverty and disadvantage where children who grow up poor, regardless of race, are more likely to be poor as adults (Wagmiller & Adelman, 2009). In many cases, the foundation of poverty can be traced to structural discrimination and racism that contribute to inequitable social and economic opportunities (ODPHP, 2020b). These deeply rooted practices and beliefs propagate the pervasive unjust treatment and oppression of BIPOC individuals (Braverman et al., 2022; see [Structural Racism and Systemic Inequities](#)). Individuals living in poverty or within impoverished communities lack equal access to the resources necessary for healthy living, such as safe, quality, stable housing and healthy food options. In the United States, BIPOC individuals living in rural areas and individuals living with disabilities are at higher risk for living in poverty.

Living in poverty has been directly linked with poor health outcomes. Those living in poverty or with limited finances may have difficulty accessing care due to the costs of health insurance, medications, and provider visits. Living in impoverished communities with limited access to healthy foods impacts health outcomes related to metabolic diseases, cardiovascular diseases, and diabetes. Living with the daily stressors of poverty and having to make difficult decisions such as *pay the rent or purchase food* increases stress levels and negatively affects mental and cardiovascular health while also negatively influencing health behaviors. Adults living in poverty are at higher risk for adverse health outcomes from smoking, substance use, and chronic stress. Poverty in childhood is associated with developmental delays, toxic stress, chronic illness, and nutritional issues. Mortality rates are higher and life expectancy is lower for impoverished individuals, families, and communities. In the United States, individuals who earn the top 1 percent of income (meaning they make more than almost everyone else) live 10 to 15 years longer than individuals who earn the bottom 1 percent of income (ODPHP, 2020b). For individuals living in poverty, economic insecurity is a constant health threat.

Employment

Employment is a main driver of individual economic stability. Stable employment is associated with lower levels of poverty and overall better health. A job's demands, the work environment, compensation, and the security of the work all affect an individual's health status (ODPHP, 2020u). Individuals may be out of the workforce (retired or unable to work), employed (working for pay), unemployed (not working but looking for work), or underemployed (involuntary part-time work, intermittent work, poverty-wage work). A lack of employment and underemployment are associated with poverty and economic insecurity. Studies have linked illness and premature death, and a delay or absence in receiving necessary medical care and prescriptions, with unemployment in adults (Kansas Department of Health and Environment, 2015). Individuals who are unemployed have higher rates of depression, anxiety, and low self-esteem along with a sense of demoralization. In addition to psychological harm, some of these individuals experience stress-related issues such as hypertension, heart disease, and arthritis and may also experience a stroke or myocardial infarction (ODPHP, 2020u).

An individual's physical work environment is an important factor in their general health. Repetitive lifting, pulling, or pushing heavy items, exposure to chemicals, or loud noises can all cause significant injury and illness to workers (ODPHP, 2020u). Time off from work often follows an injury or illness, which can further tip an individual into economic insecurity. Highly demanding jobs, high levels of conflict within the workplace, long workdays, having multiple jobs, and working evening shifts are also associated with psychological stress. These workplace stressors place individuals at risk for depression, strained caregiver-child relationships, and unhealthy coping mechanisms such as misusing alcohol or smoking cigarettes (ODPHP, 2020u). Migrant workers are at particular risk; see [Caring for Vulnerable Populations and Communities](#) for more details.

Disparities in employment have been correlated with race and ethnic background, gender, and level of educational attainment (ODPHP, 2020u). These disparities negatively impact economic stability and further perpetuate the cycle of poverty. For example, BIPOC individuals are more likely to work in lower-paying blue-collar service jobs and environments with greater exposure to the environmental risk factors described above while White individuals are more likely to work in office jobs and assume managerial positions (ODPHP, 2020u). These exposures place BIPOC individuals at higher risk for injury, illness, anxiety, and depression (ODPHP, 2020u). While the pay gap between women and men in the United States has narrowed somewhat in recent years, in 2020, women earned 83 cents for every dollar earned by men (Wisniewski, 2022). This gap in pay equity between genders negatively affects the economic stability of women and families.

Educational level affects the type of work individuals engage in, the working conditions they experience, and compensation levels. Individuals with lower levels of education generally have fewer job choices and may be forced to accept undesirable positions and low wages. These individuals are more likely to have more physically demanding jobs that may expose them to harmful toxins (ODPHP, 2020u). Many factors may contribute to lower educational attainment, including growing up in poverty with unequal access to educational opportunities.

▶ THE OPPORTUNITY ATLAS

At this interactive website, [The Opportunity Atlas](https://openstax.org/r/opportunityatlas) (<https://openstax.org/r/opportunityatlas>), you can click on a map to find out which U.S. neighborhoods offer children the best chance to rise out of poverty. You can trace the roots of today's affluence and poverty back to the neighborhoods where people grew up. The atlas allows users to search by location, outcome, and demographic group.

Explore the atlas, and then respond to the following questions.

1. What question(s) did you use to explore the Atlas?
2. What do the areas where household income at age 35 is highest seem to have in common? What about those areas where household income is lowest? And what about those where income falls somewhere in the middle? Thinking about other aspects of these regions, consider what it is about the regions—based solely on geography—that might relate to these outcomes.
3. Pick one of the articles on the map (indicated by an open book icon) and explore what you find at that link. How does this add to your understanding of poverty and opportunity?

Housing Instability

Affordable housing is another driver of economic stability, whereas **housing instability** is correlated with economic insecurity. Individuals and families who encounter difficulty paying rent, live in overcrowded residences, move frequently, or spend a large part of their household income on housing are experiencing housing instability.

Households are **cost burdened** if they spend more than 30 percent of their income on housing, and they are severely cost burdened if they spend more than 50 percent on housing (ODPHP, 2020s). After paying rent, these households are left with little to spend on other necessities such as food, clothing, utilities, and health care. BIPOC households are almost twice as likely as White households to be cost burdened (ODPHP, 2020u). In 2019, there were over 37 million cost-burdened households in the United States, almost 18 million of which were severely cost burdened. Cost-burdened households are at risk for housing instability (ODPHP, 2020u). Substandard or inferior housing is associated with health risks such as asthma, allergies, mental health conditions, and respiratory illnesses related to vermin, mold, water leaks, and inadequate heating and cooling systems (CDC, 2009).

▶ INTERACTIVITY: SPENT

In [the interactivity Spent](https://openstax.org/r/playspent) (<https://openstax.org/r/playspent>), you begin by losing your job, life savings, and house. Down to your last \$1,000, you must make it through the month by making a series of difficult decisions as you watch your savings dwindle. While this activity is set up as a game, poverty is not something you can simply stop playing, and many Americans make decisions like those in this interactive simulation daily to survive.

Walk through the interactivity, and then respond to the following questions.

1. What factors did you weigh as you decided how to spend your money?
2. What, if anything, surprised you as you made your choices?

Being cost burdened puts individuals and families at risk for foreclosure or eviction. Renters who are evicted or forced to move often relocate to poorer and less safe neighborhoods (ODPHP, 2020u). Researchers have correlated children who experience multiple housing moves in a year with poor physical health and lack of consistent health insurance coverage. If families must move frequently, building community relationships and attachments is more difficult. Community attachments can be protective for individuals experiencing adversity. For example, research has indicated that individuals living in higher-income areas report better health than those living in lower-income areas (ODPHP, 2020u).

Severe housing instability may result in homelessness, a state where individuals lack a nighttime residence ([Figure 8.3](#)). The USHUD [Annual Homelessness Assessment Report to Congress](#) (<https://openstax.org/r/hudusergov>) found that an estimated 582,500 individuals were experiencing homelessness on a single night in 2022 (USDHUD, 2022). This equates to 18 of every 10,000 individuals in the United States experiencing homelessness. Compared to the overall U.S. population, BIPOC communities continue to be overrepresented among the population experiencing homelessness (USDHUD, 2022). Individuals experiencing homelessness have an increased risk of premature death. In Massachusetts, the mortality rate of individuals ages 25 to 44 experiencing homelessness was approximately ten times higher than that of the general population. A study of individuals experiencing homelessness in the New York City shelter system found that over 50 percent had a substance use disorder, 17 percent had hypertension, 17 percent had asthma, and 35 percent were experiencing major depression, correlating the negative impact of housing instability with homelessness. Children who are homeless are at risk of cognitive and mental health problems, asthma, physical injury and assaults, and poor school performance. Housing instability has broad implications for the development and future of these children (USDHUD, 2022). See [Caring for Vulnerable Populations and Communities](#) for more information about homelessness.

FIGURE 8.3 An individual experiencing homelessness is at risk for health issues related to inadequate nutrition and exposure to violence, communicable disease, and weather. (credit: "homeless" by Golferer/Flickr, Public Domain)

THEORY IN ACTION

Moving to Opportunity

[Access multimedia content](#) (<https://openstax.org/books/population-health/pages/8-1-economic-stability>)

Neighborhoods make a difference in the health and well-being of residents. In this video, Harvard professors Nathan Hendren and Edward L. Glaeser discuss the Moving to Opportunity (MTO) program, which assessed the outcomes of moving families with young children out of high-poverty housing projects into lower-poverty

neighborhoods (ODPHP, 2020u). The program found that the children of families who moved to low-poverty neighborhoods before the age of 12 were more likely than children who didn't move or children who moved after the age of 12 to go to college, have higher incomes, and live in better neighborhoods as adults. The women of these families also had improved health outcomes, with lower levels of obesity and diabetes (Abdul Latif Jameel Poverty Action Lab, n.d.).

Watch the video, and then respond to the following questions.

1. According to the research presented, where in the United States do children have the best chance of upward mobility? Where do they have the worst chance? Why do you think this is so?
2. Why do you think children who were under age 12 when their families moved to neighborhoods with lower poverty rates fared better economically as adults than children who were older when they moved to these same neighborhoods?

CASE REFLECTION

Housing Instability

Read the scenario, and then respond to the questions that follow.

Serena Jordan is a 42-year-old woman who is married with three children, ages three, five, and nine. She works full-time as an administrative assistant at an insurance company. Her husband is a truck driver and is often gone for weeks at a time on the road. They do not have any family nearby, but they rent a second-floor apartment in an old three-family home and have made friends with the neighbors who live on the third floor. The neighbors, an older couple, sometimes help watch the children when Serena is in a pinch. Serena's family lives paycheck to paycheck, and though she works 40 hours a week, Serena is always worried about being able to pay the bills. Currently, she earns \$13/hour, and her husband brings home a salary of \$50,000/year, but with the three children, day care expenses, rent, grocery bills, car payments, and medical bills, it never seems to be enough. The family spends almost \$2,000 a month on rent, leaving them cost burdened.

1. Why do you think many people in the United States are experiencing similar situations to those Serena and her family are experiencing?
 2. What are some interventions the community health nurse can do to assist Serena and her family?
-

The Role of the Nurse in Addressing Economic Instability

Nurses need to assess for poverty in all their clients, regardless of appearance or health insurance status. This assessment can be a written questionnaire or an in-person conversation. It might be as simple as asking, “Do you sometimes have to skimp on purchasing groceries to pay your rent? Do you feel you have all the resources necessary?” Often, nurses do not want to ask these questions in case a client answers “No,” as they do not have a solution or they feel the problem is too big for one person to solve. However, the first step in the nursing process is always assessment. Nurses need to be able to ascertain this information as a part of the total health assessment to collect data and then formulate a plan. Nursing can significantly impact individuals, families, and communities living in poverty by raising awareness of the prevalence of poverty and its associated negative health outcomes. By raising awareness, nurses can advocate for allocating more resources, such as increased tax credits for families, free early education programs for young children, and better food assistance programs. Community health nurses who assess for housing instability and collect relevant data can intervene with referrals to housing support programs and subsidies that can provide low-income families with financial and housing assistance. Additionally, nurses can advocate for a living wage for everyone by promoting the health and societal benefits of improving conditions for impoverished communities.

Community health nurses can be essential in promoting safe physical work environments to address employment-related health disparities. Nurses should screen all their clients for physical and psychological work-related hazards to formulate an appropriate care plan. They can also work with local and state officials and business owners to advocate for employee benefits and resources such as health insurance, paid sick leave, and parental leave.

Community health nurses can also advocate at the local, state, and federal levels for employment programs, free educational training programs, or degree programs for lower-income individuals who wish to further their education, obtain career counseling, and seek access to affordable, quality child care. Nurses specializing in occupational health often work in tandem with corporations to promote healthy work environments. Their role is to protect workers from physical injury related to repetitive lifting or poor ergonomic design and exposure to harmful chemicals and loud noises.

8.2 Neighborhood and Built Environment

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 8.2.1 Explain the link between food insecurity and food deserts.
- 8.2.2 Describe the relationship between crime and violence and health outcomes.
- 8.2.3 Define the term *built environment*.
- 8.2.4 Examine how the built environment influences health.
- 8.2.5 Assess the effect of housing and environment on health.
- 8.2.6 Explain how environmental conditions impact population health.

Healthy People 2030 objectives focus on creating neighborhoods and environments that promote the health and safety of the places in which individuals live, work, learn, and play (ODPHP, 2020b). The neighborhoods where people reside have a major impact on their health and well-being.

Food Access

Nutritious foods are an essential component of a healthy diet. Vegetables, fruits, whole grains, low-fat dairy, protein, and oils are all nutritious foods when consumed in healthy portion sizes. Healthy eating habits, defined as eating a variety of nutrient-dense foods and beverages across all food groups within calorie limits, can lower the risk of chronic disease. Foods and beverages with added sugars, saturated fat, and sodium, along with alcoholic beverages, are associated with unhealthy diets. Research has consistently demonstrated that healthy eating habits are associated with decreased cardiovascular disease, obesity, type 2 diabetes, and breast and colorectal cancer and improved bone health (ODPHP, 2020q). Therefore, access to healthy and affordable food is vital for health.

Often a result of economic insecurity and poverty, **food insecurity** is a condition in which individuals or families have limited access to adequate amounts of high-quality food (ODPHP, 2020r). Factors influencing food security include income, employment status, race, ethnicity, and disability. Food insecurity increases when income is limited or unavailable due to unemployment. In 2020, BIPOC households were more than twice as likely as the national average to struggle with food insecurity. Individuals living with disabilities are also more likely to experience food insecurity due to limited employment opportunities and health care expenses (ODPHP, 2020r). In 2020, almost 14 million U.S. households were food insecure at some point in the year, and almost 30 percent of low-income households were food insecure compared to the national average of almost 11 percent (ODPHP, 2020r). Factors influencing this disparity are thought to be related to neighborhood conditions, transportation access, and physical access to food (ODPHP, 2020r).

Healthy food choices are inaccessible in many neighborhoods because full-service grocery stores are not readily available, particularly in certain rural areas and low-income neighborhoods (ODPHP, 2020r; U.S. Department of Agriculture [USDA], 2017). These areas where residents have limited or no options for affordable and healthy foods are often termed **food deserts** (ODPHP, 2020r; RHIhub, 2020b; USDA, 2017). Limited access to healthy and affordable food sources, income level, transportation access, and distance are barriers to healthy food access for many Americans. Almost 13 percent of the U.S. population lives in low-income food deserts (USDA, 2017). Food deserts are common in locations with small populations and high rates of vacant or abandoned homes; in areas where residents have lower incomes, lower levels of education, and higher rates of unemployment; and disproportionately within BIPOC communities (The Annie E. Casey Foundation, 2021). Lack of transportation also contributes to food insecurity. Lack of or limited public transportation is a barrier to accessing affordable healthy food. Further contributing to health disparities among vulnerable populations, individuals experiencing disabilities, those with chronic diseases, BIPOC communities, and those living in rural areas are more likely to lack transportation to full-service supermarkets (ODPHP, 2020r).

THE FOOD DESERTS OF MEMPHIS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment>\)](https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment)

This video explores food deserts by profiling two families living in Memphis, Tennessee. Their stories emphasize the contrast between the food choices available to the higher-income and lower-income areas within the city, highlighting the income and zip code divide with a 13-year life expectancy difference between the two parts of Memphis.

Watch the video, and then respond to the following questions.

1. How did you feel as you watched the video and listened to the stories? What, if anything, surprised you as you watched the video?
2. What is the relationship between the former practice of redlining and the current existence of food deserts?
3. What are some actions the community health nurse can take to address these food deserts?

In addition to accessibility issues, food affordability is a major obstacle, as healthier diets are more expensive than diets rich in processed and refined foods (The Annie E. Casey Foundation, 2021). Because nutrient-poor foods tend to be cheaper and more convenient to access than nutrient-dense foods, low-income individuals and families tend to rely on them. Convenience stores often have higher food prices with lower quality and less variety of foods than full-service supermarkets (ODPHP, 2020q). Residents of neighborhoods with fewer full-service supermarkets with fresh produce are at higher risk of obesity and diabetes, whereas rates of these conditions are lower among those who live in areas with increased access to grocery stores (ODPHP, 2020q). Studies have demonstrated a link between individuals experiencing food insecurity and higher rates of obesity and chronic diseases such as hypertension and heart disease. In children experiencing food insecurity, studies have demonstrated increased risks of obesity and developmental issues and even a negative impact on mental health (ODPHP, 2020r).

The Role of the Nurse in Addressing Food Access Disparities

Community health nurses play a major role in advocating for individuals experiencing food insecurity. School nurses nationwide have paved the way for free breakfast and lunch for students from low-income families via the National School Lunch Program (NSLP) (ODPHP, 2020r). School nurses, in conjunction with school administrators, are also at the forefront of promoting healthier food options for school-provided breakfast and lunch. Nurses both promote access to food and ensure that the food provided is nutritionally appropriate. This is one example of how community health nurses impact the health of the communities in which they serve.

Community health nurses often work with local food pantries to help families in need access food. Nurses can also help individuals obtain food benefits through programs such as Women, Infants, and Children (WIC) and the Supplemental Nutrition Assistance Program (SNAP) (ODPHP, 2020r). These government-sponsored programs provide food assistance to lower-income individuals and families. SNAP gives a monthly dollar amount, determined by income level, which must be used to purchase food. WIC is meant for pregnant, breastfeeding, or postpartum parents and for children under age five and provides nutrition education, breastfeeding support, and nutrient-dense foods (Benefits.gov, 2021). Community health nurses can advocate for increasing access to nutrient-dense foods in low-income neighborhoods to address food disparities and their subsequent negative impacts on health. At the policy level, public health nurses can be involved in policies to limit the number of fast-food restaurants in a community or to incentivize full-service supermarkets to expand into underserved neighborhoods.

Crime and Violence

Violence is a public health issue that adversely affects the target, any witnesses, the communities in which they live, and the perpetrator. It may include child abuse, firearm violence, intimate partner violence, sexual violence, or elder abuse. Violence has cumulative biological effects on the brain, neuroendocrine system, and immune response, resulting in increased incidence of depression, anxiety, posttraumatic stress disorder (PTSD), and suicide and increased risk of cardiovascular disease and premature death (Rivara et al., 2019). Repeated exposure to crime and violence is linked to an increase in negative health outcomes such as asthma, hypertension, cancer, stroke, and mental disorders (ODPHP, 2020e).

Childhood exposure to violence at home, at school, online, or in the neighborhood is considered an **adverse childhood experience** (ACE). ACEs are traumatic events such as experiencing or witnessing violence or abuse at home or in the community, having a family member attempt suicide, or any event that undermines a child's sense of safety, security, and bonding (CDC, 2022c). ACEs are linked to lifelong negative health outcomes such as chronic disease, mental illness, and substance use problems. Additionally, research has found that ACEs can negatively impact education levels, future job opportunities, and overall earning power. Evidence also links exposure to violence in childhood to an increased risk of experiencing intimate partner violence or being violent in adulthood (USDHHS Office on Women's Health, 2021). Exposure to violence as an adult is also associated with poor health outcomes, such as mental health disorders, depression, anxiety, suicidal ideation, and physical injuries from violence (ODPHP, 2020e). See [Caring for Vulnerable Populations and Communities](#) for more information on ACEs.

Individuals who are economically insecure are more likely to live in impoverished neighborhoods that lack resources and have higher rates of crime and violence (ODPHP, 2020e). Additionally, the national homicide rate is higher for BIPOC adolescents and young adults than their White counterparts (ODPHP, 2020e). Individuals who feel unsafe in their neighborhoods are more likely to avoid community gatherings and outdoor spaces, placing them at higher risk of poor physical and mental health (ODPHP, 2020e). If a community experiences violent crime, families will likely avoid utilizing public parks and partaking in outdoor physical activity out of safety concerns. This negatively affects the family, causing increased isolation and mental health stress and decreased physical activity, socialization, and play for children.

The Role of the Nurse in Addressing Violence

Strategies for public health nurses to address crime and violence include educational programs on building resilience and developing healthy interpersonal relationships. The community health nurse can collaborate to offer school-based programs that build emotional self-awareness and regulation, problem-solving, and teamwork skills to prevent violent behavior. Such educational and training programs can occur in a community center or even an outpatient community health clinic. Building resilience and emotional self-awareness and regulation skills, even from a young age, creates a culture of accountability and can reduce violence. Community and public health nurses can also offer parenting classes to help educate families on how to model resilient behaviors and give strategies for dealing with difficult parental situations. Finally, community health nurses can work with community members to provide high-quality child care, mentoring programs for young individuals, and safe, affordable after-school programs to keep children engaged with playing and learning in a supervised environment.

THEORY IN ACTION

Family Violence Prevention: Kaiser Permanente's Innovative Model

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment>\)](https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment)

In this short video, Kaiser Permanente highlights its innovative and effective model for addressing family violence and transforming the health care response to domestic violence. Community and public health nurses are well positioned in the community to utilize this approach in assessing for intimate partner and domestic violence.

Watch the video, and then respond to the following questions.

1. How does family violence impact a community?
2. What are the components of the innovative model?
3. How might a community health or public health nurse use components of this model in their communities?

The Built Environment

A community's **built environment** includes transportation access and roadways, the availability of green space, locations for community gatherings, and the buildings or other physical structures within the neighborhood (ODPHP, 2020d). Almost 20 percent of economically insecure households in the United States lack access to private transportation (Langston, 2018). Low-income individuals without a vehicle are doubly burdened if they reside in neighborhoods without adequate and affordable public transportation, such as bus routes or subways. These individuals may struggle to access schools, work, health care, and other necessary resources. Economically insecure

individuals, particularly those who identify as Black, Native American, and mixed/other race, are more likely than those who identify as White, Latina/Latino, or Asian or Pacific Islander to report dropping out of the labor force due to transportation issues (Langston, 2018).

The availability of outdoor green space and access to sidewalks and bike lanes have major health impacts on a community. A lack of green space for outdoor activities and community gatherings negatively affects residents' physical and mental health and well-being. Children need green space to play outside. Play is a means for children to learn and grow as individuals. It is difficult to socialize with groups of other children if play is limited to indoors only. Walking is a free and easy exercise activity, but residents may be hesitant to participate in this beneficial physical activity without a sidewalk or wide road shoulder to permit safe walking. Bike paths are also a cost-effective way to increase walking, biking, roller-skating, and other leisure activities and can serve as a means of transportation, but if there is not a safe way to engage in these physical activities, they will not occur.

CASE REFLECTION

Addressing the Client's Neighborhood and Built Environment

Read the scenario, and then respond to the questions that follow.

As described previously, Serena and her husband are trying to meet the basic needs of their family of five while living paycheck to paycheck. Their middle child was recently diagnosed with asthma after having numerous respiratory illnesses. The health care provider has told Serena that she should remove all carpets from the house and ensure there are no pets, woodstove smoke, or second-hand tobacco smoke near her child, as these are all possible triggers for an asthma attack. Serena is very upset, as the apartment they rent has carpet in every room except the kitchen and bathroom and her first-floor neighbors are smokers. Though Serena and her husband do not smoke, they can always smell cigarette smoke in their apartment.

1. What assessments and screenings should the nurse conduct with Serena?
2. How could the nurse assist Serena in getting some much-needed resources for her child who has asthma?
3. How might a community health nurse work with Serena and her family to find strategies to improve their living environment?

The Role of the Nurse in Addressing the Built Environment

Public health nurses are well positioned to work within the local community and government to advocate for shared public green spaces. Building community partnerships is a core policy development role for a public health nurse. From a windshield assessment of the community to raising awareness at the local level and collaborating with policymakers and community leaders, public health nurses can effect positive change within the community. Working with urban design planners and city planners, nurses can advocate for the construction of playground structures, tennis or pickleball courts, and basketball courts to afford more physical activity and community-building opportunities. School nurses can also be involved in this process by advocating for more physical education and outdoor recess time at school and by advocating for more gathering places for children and families to congregate, socialize, and play after school.

GREEN SPACE CUTS URBAN CRIME AND DEPRESSION

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment>\)](https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment)

This short video highlights how a little green space can make a big difference in low-income city neighborhoods by featuring the relationship between the environment and the health of residents living in a Philadelphia neighborhood. Community and public health nurses can be advocates and change agents, creating more green spaces in urban areas.

Watch the video, and then respond to the following questions.

1. In what ways did the neighborhood environment affect the health of its residents both before and after the

Philadelphia LandCare program?

2. Where did the intervention described in the video have the biggest impact?
3. What steps can nurses take to improve the physical environment of the clients in the communities they serve?

To find out more about the LandCare program described in the video, which is now part of the Pennsylvania Horticultural Society, [visit their website \(<https://openstax.org/r/phsonline>\)](https://openstax.org/r/phsonline).

Quality of Housing

Housing quality refers to a home's physical condition and the quality of the environment (neighborhood) in which it is located. Quality housing is characterized by clean air, home safety, enough space per individual, access to heating and cooling systems, and the absence of environmental risk factors. Crowded living conditions are associated with food insecurity, infectious diseases, and poorer mental health (ODPHP, 2020k). Low-income individuals are more likely to live in older homes and homes needing maintenance and repair.

Poor housing quality and poor living conditions contribute to negative health outcomes for a variety of reasons. The presence of lead, mold, asbestos, radon, poor air quality, and overcrowding are all associated with illness and disease. Children under age six are at increased risk for adverse health outcomes due to lead exposure because their bodies are rapidly growing and developing and because they tend to put their hands and other objects into their mouths. Children can be exposed to lead from touching, swallowing, or breathing in lead dust from lead paint, pipes, and water faucets. Lead exposure can result in slowed growth and development, damage to the brain and nervous system, learning and behavioral problems, and hearing and speech issues, all of which may result in lower IQs and underperformance in school (CDC, 2022f). Many of the outcomes associated with lead exposure are permanent; for example, lead poisoning may result in infertility, hypertension, heart disease, renal disease, and even premature death (NIOSH, 2021). Even low levels of lead in the blood have been linked to negative outcomes in a child's attention span and academic achievement (CDC, 2022f).

Many modifiable environmental risk factors related to housing are associated with negative health outcomes. Water issues such as leaking are associated with mold growth, increasing the likelihood of childhood asthma and triggering asthma exacerbation. Mold is also associated with respiratory illnesses, coughing, and wheezing. Exposure to asbestos, a class of mineral fibers used in various industrial products like insulation, cement, textured paint, and shingles, may place individuals at increased risk of developing several health conditions. Asbestos in good condition is not considered harmful, but handling asbestos products may release the fibers into the air; if inhaled, they accumulate in the lungs and may cause lung cancer, asbestosis, pleural disease, and mesothelioma (Agency for Toxic Substances and Disease Registry, 2016; CDC, 2023). While most modern products do not contain asbestos, homes built before the 1970s may have asbestos, placing families living in older rental homes at higher risk of exposure to it (U.S. Consumer Product Safety Commission, n.d.). Exposure to vermin such as cockroaches and rodents causes an increased risk for developing asthma and allergies and places exposed individuals at increased risk of psychosocial distress (CDC, 2009).

The Role of the Nurse in Addressing Quality of Housing

Community health nurses can promote the overall health and well-being of an entire neighborhood and community by addressing the quality of housing. Widespread deterioration in neighborhoods can negatively impact the mental health of residents in that community. The social and economic conditions in a neighborhood affect health outcomes as much as the quality of housing, further disadvantaging low-income groups, creating even more health disparities. To fulfill their core assessment function, community and public health nurses should assess the lived experience of community members; appropriately screen for issues such as lead poisoning, mold-related illnesses, mental health illness, and communicable diseases; and then work to develop policies to address these issues. By championing new laws and regulations on housing quality and strengthening support for affordable housing, the nurse is well positioned to lead effective change. Past successes in public health efforts on quality housing include banning lead paint products and creating local building codes and state statutes governing rental properties.

▶ COMMUNITY HEALTH & WELLNESS: HEALTH SCREENINGS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment>\)](https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment)

In this short video, FIRST 5 Santa Clara County discusses health screenings using evidence-based, standardized screening tools to identify health needs for follow-up assessments. These screenings are completed in elementary schools, preschool programs, and public health clinics, as good health is linked to readiness to learn, fostering better educational opportunities for children.

Watch the video, and then respond to the following questions.

1. How are health and education related?
2. What are some of the barriers to obtaining health care described in the video?
3. What is meant by the term *high touch, high tech*, and how is it related to the role of the nurse?

Environmental Conditions

The most common environmental conditions that may negatively impact population health are air quality, water safety, and extreme weather. Indoor and outdoor air quality is a major contributor to health.

Air Quality

Globally, air pollution is estimated to be responsible for nine million deaths per year, equating to one in six deaths worldwide (Fuller et al., 2022). The USDHHS reports that air pollution is associated with 100 to 200 thousand annual deaths in the United States (ODPHP, 2020p). Air quality is affected by pollution from smoke, dust, carbon monoxide, ozone, and nitrogen oxides. Indoor air quality can be affected by environmental smoke, cooking oils and smoke, secondhand smoke, and exposure to mold or radon. Outdoor air pollution can be affected by environmental smoke, car exhaust fumes, and other outdoor air pollutants. Pollution occurs with motor vehicles and industrial plant emissions and fires ([Figure 8.4](#)). Poor air quality can cause or exacerbate respiratory illness, and air pollution has been linked to lung cancer and heart disease. Urban communities tend to have more sources contributing to pollution and therefore tend to have worse air quality than more rural areas (ODPHP, 2020p). BIPOC communities disproportionately encounter more air pollution than predominantly White communities due to a history of structural racism. BIPOC neighborhoods are more likely to be located near factories and other industrial facilities that emit more pollution due to discriminatory city planning (ODPHP, 2020p). See [Structural Racism and Systemic Inequities](#) for more information.

Exposure to loud noises and living in close proximity to hazardous waste sites are other environmental community factors that adversely impact health. Traffic and construction contribute to noise pollution, which is associated with hearing loss and has been found to elicit stress responses in the body. BIPOC communities and low-income communities are disproportionately impacted by noise pollution. Living near hazardous waste sites or industrial facilities is also associated with increased rates of cancer, respiratory disease, skin conditions, and adverse pregnancy outcomes compared to those not living near these sites (Taylor, 2022).

FIGURE 8.4 Poor air quality affects the residents living in this area. (credit: "Wildland Urban Interface at Sherburne National Wildlife Refuge" by Russ Langford/USFWS/Flickr, Public Domain)

Water Quality

Access to safe, regulated water for drinking, bathing, and cleaning is an important determinant of health. While the U.S. water supply is generally considered safe, it can be contaminated with pathogens or chemicals that can cause illness and disease (ODPHP, 2020e). Each year, an estimated 7.2 million individuals in the United States become ill from waterborne diseases such as cryptosporidiosis, giardiasis, pseudomonas, and vibriosis (CDC, 2020b). See [Epidemiology for Informing Population/Community Health Decisions](#). The Safe Drinking Water Act (SDWA) allows the Environmental Protection Agency (EPA) to set and enforce standards for drinking water quality (CDC, 2022e). Despite these regulations, water quality can still be affected by the natural and built environment and by sociopolitical factors. Studies have found a higher risk of exposure to water contaminants, like nitrates, and arsenic, and to poor water quality in BIPOC communities and communities with lower incomes (ODPHP, 2020p). In addition, the SDWA does not regulate private wells, placing some individuals and families at increased risk for water-related issues if their wells are not properly maintained, particularly those living in rural areas without municipal water sources. Well water also has higher levels of nitrates than water from municipal water systems (ODPHP, 2020p). Arsenic is associated with nausea, vomiting, anemia, abnormal heart rhythms, and paresthesias, and nitrates decrease the blood's ability to carry oxygen to the tissues and can cause hypotension, tachycardia, headaches, gastrointestinal upset, and vomiting (CDC, 2022d).

THE ROOTS OF HEALTH INEQUITIES

Water Quality

Access to safe drinking water is a social determinant of health. Consuming contaminated water has serious negative health consequences, such as is being seen in Flint, Michigan, where children are still experiencing the consequences of lead toxicity caused by unsafe drinking water. The problem began in April 2014, when, for economic reasons, the city changed the source of its water supply from Lake Huron to the Flint River without first taking necessary corrosion control measures. This switch caused water distribution pipes to corrode, ultimately causing dangerously high levels of lead to leach into the drinking water supply. Soon after the change, residents started complaining about the water quality, noting discoloration, smell, and taste, but they were largely ignored.

Pediatrician Dr. Mona Hanna-Attisha was concerned with the number of elevated lead levels she was seeing in her clinic. She compared the blood lead levels of 1,700 Flint children prior to the water switch with their levels after the switch and found that in areas where the water lead levels were highest, there was the greatest increase in children's blood lead levels. In 2015, Dr. Hanna-Attisha sounded the alarm about her findings and held a press conference. Two weeks later, Michigan governor Rick Snyder ordered the water to be switched back to Lake Huron (Alfonsi, 2020). However, the corroded pipes continued to release lead into the drinking water. The governor declared a state of emergency in January 2016 (Ruckart et al., 2019).

Lead poisoning is a preventable environmental health threat to children, who are most susceptible to the adverse effects of lead exposure. There is no safe level of lead; it is an irreversible neurotoxin and impacts cognition and behavior, resulting in potential developmental delays and lowered IQ levels. Lead toxicity can affect every body system, causing neurological, renal, hematological, endocrine, gastrointestinal, cardiovascular, reproductive, and developmental effects. Lead also crosses the placenta, placing pregnant clients exposed to lead in danger of exposing their developing fetus. Low levels of lead in developing babies have been found to affect cognitive development and behavior (CDC, 2020a; Ruckart et al., 2019). Following the Flint water crisis, an estimated 14,000 children under the age of six may have been exposed to lead in their water. "Three years after the crisis began, the percentage of third graders in Flint who passed Michigan's standardized literacy test dropped from 41% to 10%" (Alfonsi, 2020, para. 32).

Flint is a city with a majority BIPOC population, and 40 percent of the population lives in poverty (Kennedy, 2016). Do you think complaints of discolored and foul-smelling water would have been ignored for 18 months if the demographic profile of the Flint population were different? What is the role of a community health nurse in addressing this public health issue? What interventions could the community health nurse implement to assist families affected by this crisis?

Extreme Weather

Severe weather events such as heat waves, tornadoes, and floods may cause direct injury and death or infrastructure damage that leads to negative health effects. Individuals who experience severe weather may undergo declines in mental health and worsening chronic medical conditions. Often, during severe weather events, the health care system is unable to function normally, creating a backlog of clients in addition to the increased number of individuals who require medical care from direct effects of the weather.

Severe weather events correlate with climate change, a long-term change in weather patterns that describes how rising temperatures and changes in amounts of rainfall impact the planet, with rising sea levels, shrinking glaciers, and associated changes in the blossoms of flowers and plants (Denchak & Turrentine, 2021). More than an environmental issue, severe weather due to climate change is a “fundamental threat to human health and well-being” (Levy et al., 2018, p. 1). The effects of climate change, with increasing numbers of severe weather events and shifts in weather patterns, are expected to continue. Variable weather can include unusually harsh conditions in areas that are not used to and are therefore not prepared to deal with them. Individuals and families in affected regions may experience new or exacerbated financial hardships as they manage living with extreme heat, drought, floods, or snowfall.

In areas unaccustomed to warm weather, the warming climate increases the risk of vector-borne diseases and waterborne pathogens. Warmer temperatures increase the geographic distribution of where vectors, such as mosquitoes and ticks, can survive, breed, and spread disease. Increasing rainfall, often secondary to warming temperatures, can produce standing water, creating more breeding grounds for mosquitoes. Warmer temperatures also increase the likelihood of waterborne diseases, as warmer temperatures facilitate pathogen survival, and heavy rainfall further mobilizes pathogens and compromises water and sanitation systems (Levy et al., 2018). Extreme heat is associated with respiratory and heat-related illnesses. These heat-related ailments are especially prevalent in urban areas, where the concrete footprint traps and intensifies heat, creating what is referred to as an urban heat island, a city or metropolitan area with a higher temperature than the rural areas around it.

Weather changes disproportionately affect BIPOC communities and those with low incomes due to issues around location, access to resources, and quality of infrastructure. Additionally, individuals who are Hispanic or Latina/Latino are more likely to work construction and agriculture jobs that expose them to more severe weather (ODPHP, 2020p). A study found that in 169 of the 175 largest U.S. urban areas, BIPOC individuals were more likely than White individuals to live in urban heat islands. The temperature difference between an urban heat island and an outlying area can be as high as 20 degrees Fahrenheit (Ndugga & Artiga, 2021). See [Environmental Health](#) for more information.

HOW THE ENVIRONMENT AFFECTS OUR HEALTH

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment>\)](https://openstax.org/books/population-health/pages/8-2-neighborhood-and-built-environment)

This short CDC video discusses the intersection of the environment and the social determinants of health, highlighting the importance of environmental health.

Watch the video, and then respond to the following questions.

1. What are some examples of how the environment can negatively affect health?
2. How might a nurse use tools like the CDC’s Environmental Public Health Tracking Network described in the video when caring for clients in their community?

The Role of the Nurse in Addressing Environmental Conditions

Community and public health nurses work within the core functions of assessment and policy development to monitor environmental conditions and their effects on health outcomes. They assess and monitor population health, investigating and addressing health hazards and their root causes. In areas with high levels of air pollution, these nurses monitor the community’s respiratory health, as poor air quality can cause or exacerbate respiratory health conditions. For any increased prevalence of air pollution-related respiratory issues, these nurses educate the public and mobilize community partnerships to address the issue. By cataloging the detrimental health effects of air

pollution, public health nurses have evidence to support the implementation of new laws and policies to address its causes. For residents struggling with poor indoor air quality, educating individuals and families on the importance and use of indoor air filters is a great mitigating and possibly a primary prevention intervention.

Community health nurses assess poor health outcomes related to contaminated water and investigate or address these health outcomes. While the EPA sets standards for water quality within public municipal water systems, compliance is often left to local governments. Once a link between water quality and health outcomes is established, community and public health nurses communicate with and educate the local government and the public, and they mobilize efforts to address the root cause. Using legal and regulatory avenues, the public health nurse assures that the community can access one of the most basic human rights, safe water. See [Pandemics and Infectious Disease Outbreaks](#) for more information on waterborne disease.

Community and public health nurses should familiarize themselves with environmental health concerns and join environmental nursing groups such as [the Alliance of Nurses for Healthy Environments \(ANHE\)](#) (<https://openstax.org/r/envirn>) to stay current on the latest climate change information. A national nursing organization focused on the intersection of health and the environment, ANHE offers many learning opportunities, with podcasts, webinars, newsletters, and other events. Its goal is to advance research, incorporate evidence-based practice on the environment, and influence policy (ANHE, n.d.). Massachusetts General Hospital Institute of Health Professions (MGH IHP) has opened a [Center for Climate Change, Climate Justice, and Health](#) (<https://openstax.org/r/mgihip>), created and driven by nurse scholars passionate about tackling climate change issues. This center offers many opportunities for health professionals to learn about the issues and to “address mitigation, adaptation, and resilience through education, practice, research, and service related to the health effects of climate change” (MGH IHP, 2023, para. 1).

Nurses can use information from these resources to implement community interventions and to advocate for policy changes to address climate change. Some community interventions require community health nurses to collaborate with local government, city planners, and urban designers to investigate ways to mitigate the effects of climate change, such as promoting the planting of more trees and greeneries, on the street and on rooftops, to relieve heat and improve air quality. At the family level, the community health nurse can direct families struggling with heating or electricity costs to resources such as low-income home energy assistance programs.

8.3 Educational Environment, Access, and Quality

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 8.3.1 Describe the association between health indicators and educational level.
- 8.3.2 Explain the implications of poverty, disabilities, and discrimination on learning and access to quality education.
- 8.3.3 Discuss the intersection between the social determinants of health and health literacy.

The evidence is clear: individuals with higher levels of educational attainment are more likely to live longer and healthier lives (ODPHP, 2020c). Higher levels of educational attainment refer to the education a person completes after receiving a high school diploma, such as earning an associate or baccalaureate degree. Education is one of the most important modifiable SDOH, as higher education is associated with increased healthy lifestyle behaviors and improved health outcomes. Those with higher educational attainment have greater economic resources and better access to health care (RHIhub, 2020a).

In contrast, a person is said to have low educational attainment if they have not completed high school. This is associated with economic insecurity and can result in overall worse health outcomes. The cycle of poverty and economic insecurity affects both educational access and the quality of education. Individuals in impoverished neighborhoods often have less access to community resources and wield less effective political influence, rendering them less able to demand higher-quality schools. Lower-quality schools lack the resources to support students, resulting in significant educational opportunity gaps based on neighborhood and school district. For example, children from low-income families are more likely to struggle with math and reading. They are less likely to graduate from high school and go to college than children from higher-income families (ODPHP, 2020c). Academically gifted children attending public schools in low-income areas are also less likely to have access to gifted and talented programs if their schools do not offer these resources or if their families cannot afford to access them elsewhere.

(Yaluma & Tyner, 2021). The stress of living in poverty can adversely affect a child's brain development, making it harder for them to do well in school (ODPHP, 2020c). This can have a domino effect, as a college education is associated with safer and higher-paying jobs; individuals who do not graduate from high school or go to college are more likely to have chronic health problems (ODPHP, 2020c).

THE ROOTS OF HEALTH INEQUITIES

The Educational Roots of Health Inequities

The educational roots of health inequities result from institutional and systemic biases in policies that separate individuals into either resource-rich or resource-poor neighborhoods, as these neighborhoods dictate school access. This separation into resource-rich or resource-poor neighborhoods is principally based on socioeconomic position and race, resulting in wide health disparities in life expectancy and health outcomes, as education is a major factor in shaping the course of an individual's life.

(See Weinstein et al., 2017.)

Early Childhood Development and Education

A child's first 5 years of life are critical for cognitive, emotional, and physical growth and development. A healthy, safe, and stable early childhood helps determine if a child will have a healthy, happy life. A variety of social, environmental, and economic factors greatly affect early childhood development. Risk factors for potential developmental delays and future poor health outcomes include early life stressors, low income, and lack of access to quality early educational programs. In contrast, protective factors include higher socioeconomic status (SES), stable relationships with caregivers, and access to quality early education programs (ODPHP, 2020m).

As mentioned previously, early life stressors and ACEs impact a child's health. Early life stressors such as physical abuse, family instability, poverty, and unsafe environments contribute to developmental delays and poor health outcomes later in life. These children may lack adequate coping skills and have difficulty regulating their emotions and behaviors, thereby struggling in early childhood education programs (ODPHP, 2020m). Inadequate social functioning skills like lack of impulse control, difficulty forming relationships, and trouble regulating behaviors can negatively impact a child's ability to learn or connect with peers in early elementary school programs.

Poverty, by itself, negatively impacts children's academic achievement. Research has demonstrated that children from disadvantaged backgrounds are more likely than other children to repeat grades and drop out of high school (ODPHP, 2020m). Children from communities with higher SES and more resources have been shown to experience safer and more supportive environments and better early education programs. Quality early childhood programs help foster the mental and physical development of children. They are linked to increased earning potential and higher educational attainment (ODPHP, 2020m).

Early childhood education programs can help reduce educational gaps. [Head Start \(<https://openstax.org/r/eclkc>\)](https://openstax.org/r/eclkc) is a federally funded early childhood program that supports children from low-income families. It provides comprehensive services and strives to improve health, increase learning and social skills, and prepare young children for kindergarten. Studies have demonstrated that children who experience quality early education programs like Head Start that are comprehensive and include health care and nutritional components partake in less risky health behaviors such as binge drinking alcohol, smoking cigarettes, and using illegal substances and have lower risks for heart disease, obesity, hypertension, hyperglycemia, and hypercholesterolemia (ODPHP, 2020m). Quality comprehensive early childhood development and education programs reduce risky health behaviors and prevent or delay the onset of chronic disease in adulthood.

The quality of education in elementary schools is an important determinant in the health and well-being of children. Receiving a high-quality elementary school education reduces educational disparities in children. Children attending a school with safety concerns, limited health resources, and low teacher support are more likely to experience adverse physical and mental health. Until disparities in access to quality early childhood development programs and quality school systems are addressed, children without access will suffer worse health outcomes (ODPHP, 2020m).

THEORY IN ACTION

Brain Architecture in Early Childhood

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-3-educational-environment-access-and-quality>\)](https://openstax.org/books/population-health/pages/8-3-educational-environment-access-and-quality)

In this University of Minnesota Center for Early Education and Development video, Dr. Megan Gunnar discusses the impact of early childhood development on the future abilities and health outcomes of children.

Watch the video, and then respond to the following questions.

1. How does early childhood development affect learning later in life?
2. List five ways families and communities can help build a strong and proper brain foundation in early childhood.
3. How does a strong brain foundation impact health outcomes?

High School Graduation

Most jobs require at least a high school (secondary) education. Individuals who do not complete high school have limited employment opportunities, earn lower wages, and are more likely to live in poverty. Disparities in high school completion rates exist by racial and ethnic groups with Black and American Indian/Alaska Native students having the lowest graduation rates (ODPHP, 2020o). Students' home and school environments impact their chances of graduating from high school. High school graduation can be affected by family support, the school district, resources within the school, and the greater community.

Lack of parental involvement in school is linked to lower graduation rates. Teacher quality is also a critical factor; students who believe their teachers are of high quality and that they care are more likely to graduate, whereas students who feel their teachers are uninterested in teaching are more likely to drop out (ODPHP, 2020o). Violence and safety concerns also affect high school dropout rates. Low-income families often live in neighborhoods where schools lack resources and underperform. These factors contribute to higher dropout rates and lower academic achievement. In 2016, low-income families were almost four times more likely than high-income families to have a student not complete high school (ODPHP, 2020o). Economically insecure BIPOC communities are disproportionately represented with lower educational attainment in comparison to economically insecure White individuals. Approximately 85 percent of economically insecure White adults have at least a high school diploma, whereas only about 50 percent of economically insecure adults who identify as Latina/Latino have attained their diploma (Langston, 2018).

Reading skill level in third grade is linked to high school completion rates. One Annie E. Casey Foundation study found that almost a quarter of students with below-basic reading skill level in the third grade failed to finish high school compared with 4 percent of students with third-grade proficient reading skills who failed to finish high school (ODPHP, 2020o). Twenty-six percent of students who were not reading at the proficient level in third grade and who had lived in poverty for at least one year during their school years did not finish high school on time or at all (ODPHP, 2020o). Teen pregnancy and parenthood are also risk factors for dropping out of high school, as only half of teens who have given birth earn a high school diploma.

Many positive outcomes come with graduating from high school. Individuals with a high school diploma have a decreased risk of premature death, more employment opportunities, and a higher lifetime earning potential (ODPHP, 2020o). Lacking a high school diploma is associated with self-reported overall poor health and chronic health issues such as asthma, diabetes, heart disease, hypertension, and hepatitis. Additionally, individuals with a high school diploma who are employed full-time earn almost 25 percent more than those who are employed full-time without a high school diploma (ODPHP, 2020o). Supporting individuals to graduate high school is an important public health intervention.

Enrollment in Higher Education

Higher education refers to any education after high school, including community colleges, vocational and technical schools, colleges, and universities. Many higher-paying jobs require a college degree; less than one in five

economically insecure individuals have a college degree, whereas half of economically secure individuals do (Langston, 2018). College graduates have more employment options than individuals without college degrees. On average, lifetime earnings for individuals with a bachelor's degree are double those of individuals without a degree (ODPHP, 2020n). Higher education is associated with better-paying, less hazardous jobs. This all supports an individual's health, as the higher their income, the greater their ability to secure material and social resources like higher-quality housing and social status (ODPHP, 2020n). Overall, higher education is associated with improved health and a decreased risk of premature death. Individuals with more education are more likely to partake in healthy behaviors, such as drinking less alcohol, exercising regularly, and seeking preventive health care when needed (ODPHP, 2020n).

How well an individual's middle and high schools prepare them for college greatly influences their likelihood of graduating. Students who attend high schools that do not provide honors or advanced courses may be less academically prepared for college-level work than students who attend high schools that provide these courses (ODPHP, 2020n). Students without access to a consistent guidance counselor may not receive help navigating the college application and admissions process. In many low-income neighborhoods, schools lack the financial resources necessary to offer these courses and dedicated guidance counselors, potentially lowering college admissions rates for their students (ODPHP, 2020n).

While the diversity of undergraduate college students is increasing, BIPOC individuals still demonstrate lower levels of academic persistence in college compared to their White counterparts (ODPHP, 2020n). Black and Hispanic individuals also have lower college enrollment and graduation rates. These lower enrollment and graduation rates may be affected by the discrimination, social isolation, and stress of debt accumulation that these students face (ODPHP, 2020n). BIPOC students experience discrimination at rates two to four times higher than White students, and in a study up to a quarter of these students reported feeling that the discrimination they experienced adversely affected their academic outcomes (Stevens et al., 2018). Barriers to higher education exist, but strengthening the curriculum in school districts in lower-income communities and offering more teacher and guidance counselor support can help to better prepare students for the admissions process and the rigors of college (ODPHP, 2020n).

The Role of the Nurse in Addressing Educational Disparities

Community and public health nurses play an important role in early childhood, primary, and secondary education. Partnering with school nurses and administrators, community and public health nurses can use their assessment data as a foundation to influence policy development at the local level. By analyzing trends in the data and presenting this information to the local school committee and city officials, nurses can advocate for meaningful change, such as creating or expanding Head Start programs to ensure equal access to evidence-based successful early childhood education programs. Community and public health nurses can also advocate for increased funding for school districts to create high-quality primary education. Community and public health nurses can advocate for and support transition programs to support students moving from middle to high school. Additionally, nurses can advocate for advanced courses and other programs that better prepare students for the future. These types of programs can encourage students to continue with their studies.

EDUCATION GAP: THE ROOT OF INEQUALITY

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-3-educational-environment-access-and-quality>\)](https://openstax.org/books/population-health/pages/8-3-educational-environment-access-and-quality)

In this video, Harvard University's Director of the Achievement Gap Initiative, Ronald Ferguson, discusses educational inequality and encouraging efforts that are being made in Boston to address these gaps. This is an example of a community-level approach to addressing educational inequalities that a community and population health nurse can spearhead and lead.

Watch the video, and then respond to the following questions.

1. Why do you think educational gaps exist?
2. How do you think the Boston Basics program can help address these educational gaps?
3. What is the community health nurse's role in addressing and responding to these educational gaps?

Language and Literacy

Literacy refers to listening and speaking skills, reading and writing skills, and cultural and conceptual knowledge. Health literacy refers to an individual's ability to find, understand, and use health-related information (ODPHP, 2020t). Low literacy skills are linked with lower educational attainment, poorer health outcomes, and chronic diseases like diabetes and cancer (ODPHP, 2020l).

Limited English proficiency (LEP) can be a barrier to accessing health care services. Individuals with limited English proficiency tend to be immigrants to the United States who may speak another language at home. In 2019, almost 22 percent of the U.S. population ages five and above spoke a language other than English at home, and among these individuals, 39 percent reported speaking English less than very well (ODPHP, 2020l). Individuals who identify as having limited English proficiency are less likely to have a primary care provider and, therefore, less likely to have preventive health care (ODPHP, 2020l). These individuals also encounter difficulty following medication instructions and communicating with health care providers.

Many barriers impede individuals with limited English proficiency from receiving appropriate health services. A lack of trained interpreters and culturally responsive health care providers adversely affects their health. Cultural barriers, language barriers, and financial difficulties create significant obstacles for immigrants trying to access health information (ODPHP, 2020l). Language barriers create a quality-of-care issue, especially if the provider is not linguistically competent, and a lack of quality trained interpreters impedes access to mental health services for individuals with limited English proficiency (ODPHP, 2020l). See [Culturally and Linguistically Responsive Nursing Care](#) for more information on this topic.

CASE REFLECTION

Client Education

Read the scenario, and then respond to the questions that follow.

Serena and her children attend the local community center's biannual fair. Twice a year, the community center hosts this one-day event for the community's residents, where they have food, games, health screenings, health promotion education events, yoga, senior center representatives, and sign-up sheets for various community groups. Serena decides to have her blood pressure (BP) taken at the screening tent. Her BP reading is 162/92. The nurse takes it manually and repeats it two times, but the readings are similar. The nurse asks Serena about any medical history of daily medications, but Serena shakes her head no. She feels lucky to be healthy overall and does not take any medications except for ibuprofen for headaches occasionally.

1. What factors could be contributing to Serena's elevated blood pressure?
2. What lifestyle questions could the nurse ask Serena to develop a health teaching plan for her?

8.4 Social and Community Context

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 8.4.1 Describe the impact of civic participation on individual health.
- 8.4.2 Define discrimination and discuss its impact on the social determinants of health.
- 8.4.3 Explain how incarceration is linked to the other social determinants of health.
- 8.4.4 Discuss the importance of social capital and cohesion in relation to health outcomes.

The social and community context determinant of health includes civic participation, discrimination, incarceration, and social cohesion. Because relationships with family, friends, colleagues, and neighbors greatly impact health and well-being, Healthy People 2030 focuses on increasing social and community support (ODPHP, 2020f). Positive relationships help buffer the negative effects of unsafe neighborhoods, discrimination, and poverty and, by extension, improve overall health and well-being (ODPHP, 2020f).

Civic Participation

Civic participation refers to a range of activities that benefit the community and provide health benefits for

participants (APA, 2023). Civic participation helps build **social capital**, the value gained from having positive interactions and connections between people that enables the community to function effectively and collaboratively in problem-solving efforts. It is these relationships and networks that support the neighborhood and community. By building social capital via civic engagement, members of civic groups are more likely to be physically active and to engage in meaningful activities, providing a sense of purpose (ODPHP, 2020g). Examples include volunteering at community parks, nature reserves, senior centers, community centers, and adult day centers. It can also include civic engagement in the form of environmentalism, education, recycling efforts, composting, farming, and community gardening. Overall, volunteers experience increased psychological well-being and emotional health (ODPHP, 2020g), and adult volunteers aged 60 and above have a lower risk of cognitive impairment (Infurna et al., 2016). Community gardening is associated with increased neighborhood pride, motivation to be involved, and access to healthy foods ([Figure 8.5](#)) (ODPHP, 2020g). Group membership has also been found to increase social capital and benefit members by increasing opportunities for social gatherings. Groups such as the Lions Club, Girl Scouts, and Rotary International clubs can be formal, and there can be informal groups, such as book clubs and walking groups (ODPHP, 2020g). Ultimately, individuals and families who are active in their community and have connections with other individuals in their community are happier and healthier.

FIGURE 8.5 Volunteering at a community garden allows residents to socialize and access fresh produce. (credit: "Community Garden" by Kevin Krejci/Flickr, CC BY 2.0)

Discrimination

As discussed in [Structural Racism and Systemic Inequities](#), **discrimination** refers to unfair treatment of individuals and groups based on certain characteristics such as race, ethnicity, gender, age, religion, sexual orientation, and ability (ODPHP, 2020h). It assigns value based on the social interpretation of how one looks or acts, and it manifests in social actions aimed at protecting more privileged groups at the expense of less privileged ones (ODPHP, 2020h). Discrimination is prevalent in the United States, where 63 percent of adults report experiencing discrimination every day, impacting a variety of population groups, such as older adults, certain ethnic and racial groups, individuals identifying as lesbian, gay, bisexual, transgender, and queer/questioning, (LGBTQ), and individuals experiencing disabilities (ODPHP, 2020h). Discrimination is a public health threat. It can precede stress-related emotional, physical, and behavioral changes, resulting in adverse health outcomes across the age spectrum (APA, 2022). These adverse health outcomes include tachycardia, anxiety, hypertension, and gastrointestinal ulcers that lead to negative long-term health outcomes over time. [Caring for Vulnerable Populations and Communities](#) discusses the effects of discrimination on health outcomes in more detail.

Discrimination occurs at both the individual and structural levels. **Structural discrimination** refers to institutional policies, systems, laws, and practices that limit individuals' and populations' opportunities, resources, and power based on race, ethnicity, gender, ability, SES, and religion. These deeply rooted practices and beliefs propagate pervasive unjust treatment and oppression of individuals (Braveman et al., 2022).

Discrimination based on race has been linked to significant disparities in health outcomes, attributed to the cumulative effects of racism on the body. Structural racism in health care often results in Black clients receiving poorer-quality care. The 2019 National Healthcare Disparities Report found that White clients receive a better quality of care than almost 41 percent of Black clients (Taylor et al., 2019). In 2018, non-Hispanic Black infants in

the United States had 2.4 times the infant mortality rate of White infants (USDHHS Office of Minority Health, 2021). This disparity is rooted in racism; structural racism has resulted in Black women receiving poorer-quality care. On an individual level, the stress from enduring discrimination and racism is cumulative and triggers biological processes that places these women at higher risk for pregnancy-related complications such as preeclampsia, eclampsia, embolisms, and mental health related issues (Taylor et al., 2019). [Structural Racism and Systemic Inequities](#) discusses race-based structural discrimination in more detail.

THEORY IN ACTION

What Is Intersectionality?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-4-social-and-community-context>\)](https://openstax.org/books/population-health/pages/8-4-social-and-community-context)

This animation defines *intersectionality* and explores the reasons why common approaches of addressing discrimination fall short in addressing all the negative factors that may hinder an individual's well-being.

Watch the video, and then respond to the following questions.

1. How would you explain intersectionality?
2. How can the nurse apply the concept of intersectionality in community health nursing?
3. Can you think of any client encounters from clinical or work experiences where you witnessed the intersection of multiple forms of discrimination at one time? How did this make you feel?

Incarceration

Incarceration refers to confinement in a prison or a jail. Incarceration affects the health of those incarcerated and their families and communities. BIPOC communities and individuals with lower levels of education are disproportionately affected by higher incarceration rates due to the federal policies of the 1960s and 1970s resulting in increased police surveillance and mass incarceration. As of 2018, Black Americans were incarcerated at more than five times the rate of White Americans (Gramlich, 2020). That year, Black Americans represented approximately 12 percent of the U.S. adult population, yet they represented 33 percent of the incarcerated population, while White Americans represented 63 percent of the U.S. adult population and comprised 30 percent of the incarcerated population (Gramlich, 2020). During this same time period, Hispanic Americans represented 16 percent of the U.S. adult population but accounted for 23 percent of the incarcerated population (Gramlich, 2020). Data indicates that White men without a high school diploma or General Education Development (GED) equivalent have a significantly higher risk of being incarcerated (1 in 8) when compared to their more educated peers (1 in 57) (ODPHP, 2020i). Communities with higher rates of poverty and unemployment are disproportionately burdened by higher incarceration and recidivism (being arrested or incarcerated again) rates (ODPHP, 2020i). [Structural Racism and Systemic Inequities](#) and [Caring Across Practice Settings](#) discuss issues related to incarceration in more detail.

Individuals with a history of incarceration have been found to have worse physical and mental health compared to the general population. Women in this demographic are more likely to have experienced ACEs than women not in the criminal justice system, illustrating how early childhood experiences place certain individuals at higher risk for adverse life outcomes (ODPHP, 2020i). Individuals who have experienced incarceration have higher rates of mental health disorders, hypertension, asthma, cancer, arthritis, tuberculosis, hepatitis C, and HIV (ODPHP, 2020i). This heavy disease burden has implications for when these individuals reenter the community. Already at a financial disadvantage, they may have trouble finding employment and a place to live given their criminal record and lack the resources to seek the medical care needed to manage their conditions. This reinforces the cycle of poverty and poor health outcomes. The United States releases millions of individuals from jail and prison each year, yet recidivism is fairly common, as more than 50 percent of individuals are incarcerated again within 3 years of their initial release. This may be due to the obstacles these individuals face when reentering society (ODPHP, 2020i).

Incarceration often negatively impacts the families of those individuals who are incarcerated. Almost half of incarcerated individuals have minor children, about 19 percent of whom are age 4 or younger (Wang, 2022). Having a parent incarcerated is considered an ACE because it places these children at higher risk for cognitive and health-related challenges throughout their lives and because they are more likely to live in poverty and be homeless.

(ODPHP, 2022i). These children have higher rates of developmental delays, learning difficulties, speech and language issues, attention disorders, and aggressive behaviors, and they are up to five times more likely to be involved with the criminal justice system than children without incarcerated parents (ODPHP, 2020i). Illustrating the generational effects of parental incarceration as an ACE, many incarcerated parents also grew up in challenging situations:

- 17 percent spent time in foster care.
- 43 percent are from families that received public assistance.
- 19 percent lived in public housing before the age of 18.
- 11 percent were homeless at one point before the age of 18.
- 32 percent had or currently have an incarcerated parent (Wang, 2022).

Community and public health nurses have a role in identifying children who are at risk due to parental incarceration. After identification, nurses can begin a targeted approach to secure access to resources and educational programs aimed at supporting these children and their caregivers. This involves an interprofessional team of school nurses, guidance counselors, and therapists and early childhood educational programs for those that qualify. Community and public health nurses can collaborate with the justice system to advocate for programs such as drug treatment courts to help keep individuals out of prison while treating their addiction (ODPHP, 2020i). Correctional nurses can provide and advocate for comprehensive health services during incarceration to address the individual's holistic needs (ODPHP, 2020i; see [Caring Across Practice Settings](#)). Community nurses can help individuals who reenter the community access health care, employment resources, food, and housing.

Social Cohesion

Social cohesion refers to the strengths of relationships within a community (ODPHP, 2020j). An indicator of social cohesion is the amount of social capital within a community. Places of worship, community centers, libraries, and families are common sources of social capital. **Collective efficacy** is another aspect of social cohesion and is based on trust. It refers to a community's ability to create change and influence behavior through social norms (ODPHP, 2020j). This is associated with improved self-rated health, lower rates of neighborhood violence, and improved access to medical care, healthy food, and places to exercise (Matsaganis & Wilkin, 2015).

Research has demonstrated that high levels of social support positively influence health outcomes such as healthier eating habits, exercise, and even dealing with stress (ODPHP, 2020j). For example, social support contributes to lower atherosclerosis levels (Shah et al., 2021) and is a protective barrier to the harmful consequences of discrimination for many first-generation immigrants (Szaflarski & Bauldry, 2019). Many studies have linked social isolation to detrimental health effects and increased overall mortality, especially in older adults (ODPHP, 2020j). The CDC considers loneliness and social isolation in older adults a significant public health threat, with almost one quarter of adults ages 65 and older considered socially isolated (CDC, 2019). Social isolation also disproportionately affects vulnerable populations, including immigrants and lesbian, gay, bisexual, and transgender (LGBT) populations (CDC, 2019). Social isolation and loneliness are associated with the following health outcomes (CDC, 2019):

- 50 percent increased risk of dementia
- 29 percent increased risk of heart disease
- 32 percent increased risk of stroke
- Higher rates of depression, anxiety, and suicide

Social networks are foundational to a healthy and thriving community. They create social cohesion, can spread positive health behaviors, and give a sense of community to individuals and families (ODPHP, 2020j). Community and public health nurses are well positioned to foster the development of social networks, especially in vulnerable populations. Through senior centers, councils on aging, ethnic centers, local Boys and Girls Clubs, local Y clubs (formerly known as the YMCA), libraries, local government offices, and assisted living facilities, community health nurses can nurture the development of community groups and events ([Figure 8.6](#)). By helping to develop programming to refer at-risk individuals and families to existing programs, nurses can make an impact.

FIGURE 8.6 A community center provides a location for children and families to gather and build social capital. (credit: "Community Center" by Billy Brown/Flickr, CC BY 2.0)

THEORY IN ACTION

County Health Rankings Model

[Access multimedia content \(<https://openstax.org/books/population-health/pages/8-4-social-and-community-context>\)](https://openstax.org/books/population-health/pages/8-4-social-and-community-context)

The University of Wisconsin Population Health Institute, with the Robert Wood Johnson Foundation's support, has conceptualized a population health model illustrating a broad vision for health, demonstrating how policies and programs shape a community's health and outcomes, both quantity and quality of life. This video highlights this model, showing all the factors that impact health (the SDOH) and demonstrating that upstream interventions can be implemented at the population health level to ensure that each individual and community thrives.

Watch the video, and then respond to the following questions.

1. What are your impressions of this model?
2. Do you feel the model is an accurate representation of the intersection of health and social, economic, and environmental factors? Why or why not?
3. How might one use this model in population health nursing?

[Explore the model \(<https://openstax.org/r/explorehealth>\).](https://openstax.org/r/explorehealth)

8.5 The Cumulative Effect of Inequalities on Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 8.5.1 Define *health equity* and *health inequity*.
- 8.5.2 Describe health disparities in the context of SDOH.
- 8.5.3 Describe the cumulative impact of inequalities on individual and population health.

Social determinants of health contribute to preventable health disparities, and these disparities may result in **health inequities**, “differences in health status or health resources between different population groups, arising from the social conditions” (WHO, 2018, para. 2). Health inequities are more than just a lack of equal access to necessary resources; they are a result of an unjust system.

Equality refers to situations where each individual is given the same resources or opportunities. **Equity** recognizes that everyone is not the same and distributes the exact resources or opportunities needed by each individual to reach an equal outcome among individuals (Milken Institute School of Public Health [MISPH], 2020). The World Health Organization defines *equity* as the “absence of unfair, avoidable or remediable differences among groups of people, whether those groups are defined socially, economically, demographically, geographically or by sex, gender, ethnicity, disability, or sexual orientation” (WHO, 2021, p. 2). Equity is needed to address the historical injustices that have perpetuated structural racism and discrimination. It is a means to address the imbalance and injustice in

our social systems. *Social justice* refers to overhauling social systems with the goal of sustainable, equitable access into the future (MISPH, 2020).

To achieve health equity, rather than treating everyone in the same way, individuals and communities need to be given resources and opportunities that align with their circumstances (MISPH, 2020). According to the CDC, achieving health equity requires an enduring effort to address historical and contemporary injustices to surmount obstacles to health care and eliminate health disparities (CDC, 2022g). To reduce health disparities, individual needs should be addressed holistically.

The SDOH have a greater influence on health outcomes than clinical care. Clinical care impacts only 20 percent of health outcomes, whereas socioeconomic factors account for 47 percent of health outcomes, and health behaviors account for 34 percent of overall health outcomes (Whitman et al., 2022). Social determinants have a much greater impact than biology or medicine. Within these social factors, there are many inequities. Addressing these differences in SDOH is a step toward health equity (CDC, 2022a). Racism and other SDOH are central drivers of health disparities and inequities within BIPOC communities, creating inequities in access to housing, education, wealth, and employment, thereby placing these individuals at higher risk for poor health (CDC, 2022a). The SDOH are at the root of many health inequities resulting from the unequal conditions in the social and physical environment. It is widely accepted that to influence the health of a population, there needs to be a focus on improving social conditions and addressing those SDOH (CDC, 2022a). Just as nurses assess for medication allergies and medical history, the SDOH need to become a part of every conversation as a foundation to holistically provide appropriate care and services to individuals and families in need.

THEORY IN ACTION

Screening for the Social Determinants of Health

The American Academy of Family Physicians has created [a program called The EveryONE Project](https://openstax.org/r/familyphysician) (<https://openstax.org/r/familyphysician>) to assist health care professionals in advocating for health equity. As a part of this program, it has created a screening tool to assist health professionals in screening every client for the social determinants of health.

Visit its website to read the guide, and then respond to the following questions.

1. How did you feel as you read the team-based approach of The EveryONE Project?
2. Do you think that as a nurse, you will be able to effectively screen clients for the SDOH using this tool? Why or why not?
3. Do you think the health care community has an ethical duty to act and to do more to address the SDOH? Why or why not?

Chapter Summary

8.1 Economic Stability

Economically stable individuals and families have a steady source of income with consistent access to the resources that are essential for a healthy life, such as food, clothing, safe housing, transportation, quality child care, quality education, and health insurance. Almost 12 percent of the U.S. population lives in poverty and experiences economic insecurity. BIPOC communities comprise half of the individuals who are economically insecure, and the cycle of poverty often persists across generations. Poor health outcomes, including early cardiovascular disease, metabolic disease, diabetes, and mental health disorders, are directly linked to living in poverty, illustrating the concept of the socioeconomic gradient.

8.2 Neighborhood and Built Environment

Neighborhoods and the built environment, including the quality and safety of water, air, and soil, the quality and safety of the community's infrastructure, housing, transportation, and roadways, and access to healthy foods that support positive eating patterns, directly impact health. Locations with limited options for affordable and healthy foods are considered food deserts. Neighborhood safety is a huge public health concern. ACEs are more likely to occur in lower-income communities; are linked to lifelong mental illness, chronic disease, and substance use; and negatively impact education and future earning power. Housing quality is an important determinant of health, as lead, mold, asbestos, vermin, and even crowded living conditions are all modifiable environmental risk factors associated with poor health outcomes.

8.3 Educational Environment, Access, and Quality

Education is one of the most important modifiable SDOH; increased educational attainment is associated with an increase in healthy lifestyle behaviors and improved health outcomes. Individuals living in impoverished neighborhoods often have less access to community resources, such as high-quality schools, resulting in significant disparities in educational

Key Terms

adverse childhood experience (ACE) a traumatic incident such as experiencing violence or abuse, witnessing violence at home or in the community, having a family member attempt suicide, or any event or environment that undermines a child's sense of safety, security, and bonding

opportunities. Quality early childhood education programs can help reduce educational gaps, but access remains an issue. Fostering quality, accessible, and affordable early childhood education programs can positively impact educational attainment levels. Encouraging and assisting all students to achieve a high school diploma is associated with better employment opportunities and higher-paying jobs, resulting in overall improved health.

8.4 Social and Community Context

Positive community relationships and civic participation can help buffer the negative impact of unsafe neighborhoods, poverty, and discrimination. Social capital is associated with more physically active, happier, and healthier lives. Discrimination in any form is a public health threat. Structural discrimination is at the root of health disparities seen in BIPOC individuals. The SDOH are intricately tied to structural discrimination, racism, and persistent health disparities. High levels of social support positively influence health outcomes and decrease the incidence of social isolation and its negative impact on mental and physical health.

8.5 The Cumulative Effect of Inequalities on Health

The SDOH have a greater influence on health outcomes than clinical care. Racism and other SDOH are central drivers of health disparities and inequities within BIPOC communities, creating inequities in access to housing, education, wealth, and employment, thereby placing these individuals at higher risk for poor health. Equity is needed to address the historical injustices that have perpetuated structural racism and discrimination. To influence the health of a population, it is necessary to focus on improving social conditions and addressing the SDOH. To reduce health disparities, individual needs must be addressed holistically. The Future of Nursing 2020-2030 report highlights health equity as a major focus for nursing, and this begins with assessing the SDOH with every client encounter.

built environment includes transportation access and roadways, the availability of green space, locations for community gathering, and the buildings or other physical structures within the neighborhood

civic participation a range of activities that

individuals can participate in that benefit the community as well as participant health	from social conditions
collective efficacy a community's ability to create change and influence behavior through social norms	housing instability a situation where individuals and families have difficulty paying rent, live in overcrowded residences, move frequently, or spend a large part of their household income on housing
cost burdened describes households in which more than 30 percent of income is spent on housing	living wage payment for employment that affords a modest standard of living for the individual and family
discrimination unfair treatment of individuals and groups based on characteristics such as race, gender, age, sexual orientation, and ability	poverty a state in which an individual lacks a socially acceptable amount of money or possessions
economic insecurity a situation linked to poverty where an individual or family is unable to consistently afford housing, food, clothing, transportation, child care, or health care	social capital value gained from having positive interactions and connections between people that enables the community to function effectively and collaboratively in problem-solving efforts
economic stability a situation where the individual has a steady source of income and consistent access to resources essential for a healthy life	social cohesion the strengths of relationships within a community; an indicator is the amount of social capital, or shared group resources, within a community
equality a situation where each individual is given the same resources or opportunities	social determinants of health (SDOH) the conditions in the environments where people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks
equity the distribution of the resources or opportunities each individual needs to reach an equal outcome among individuals	social justice the view that everyone deserves equal rights and opportunities; also refers to overhauling social systems with the goal of sustainable equitable access into the future
food deserts areas where residents have limited or absent options for affordable and healthy foods	socioeconomic gradient the association between low socioeconomic position (SEP) and increased disease risk and premature death
food insecurity a condition in which individuals or families have limited access to adequate amounts of food	socioeconomic position (SEP) one's position in society based on social and economic factors of income, education, and employment
generational poverty a persistent lack of a socially acceptable amount of money or possessions and disadvantage where children who grow up poor are more likely to be poor as adults	structural discrimination deeply rooted institutional policies, systems, laws, and practices that limit opportunities, resources, and power of individuals and populations based on race, ethnicity, gender, ability, SES, and religion
health disparities preventable differences in health between groups of individuals, usually resulting from social or economic factors, geographic location, and environment	
health equity a state in which everyone has a fair and just opportunity to attain their highest level of health	
health inequities differences in health status or health resources between population groups arising	

Review Questions

1. Which of the following is a social determinant of health?
 - a. Where you live
 - b. Health behaviors
 - c. Genetic makeup
 - d. Age

2. What is the main driver of economic stability?
 - a. Health
 - b. Food cost
 - c. Employment
 - d. Transportation access

3. Which of the following neighborhood factors is considered an adverse childhood experience?
 - a. Absence of sidewalks to walk to school safely
 - b. Access to green spaces
 - c. Relying on readily accessible public transportation
 - d. Exposure to crime and violence
4. What is the connection between education and health?
 - a. Attending a lower-quality school is associated with health literacy
 - b. Higher education means higher socioeconomic position
 - c. Higher educational attainment is associated with higher health literacy rates
 - d. Health is not adversely impacted by the quality of education
5. Which of the following activities is an example of building social capital?
 - a. Volunteering at the local community center
 - b. Attending parent-teacher conferences at the school
 - c. Composting in your own backyard
 - d. Utilizing the library to check out movies
6. Which of the following scenarios is an example of health equity?
 - a. Providing mobile health screenings for individuals without transportation
 - b. Offering clinic appointments during standard business operating hours
 - c. Providing a health education session in English only
 - d. Offering all clients a fasting glucose screening at age 40
7. Which of the following is an example of a health disparity?
 - a. BIPOC clients who are pregnant experience the highest rates of infant mortality
 - b. Heart disease and cancer are the two leading causes of death across race, gender, and ethnicity
 - c. Older adults have worse overall health outcomes compared with young adults
 - d. Professional tennis players tend to have a higher prevalence of elbow injuries
8. How much does clinical care impact an individual's health outcomes?
 - a. 34 percent
 - b. 10 percent
 - c. 20 percent
 - d. 47 percent
9. Why does the nurse assess the SDOH when caring for individuals and their families in the community?
 - a. The SDOH have a significant impact on the health, wellness, and quality of life of individuals and families
 - b. By assessing the SDOH, the nurse can standardize interventions based on where the individual and family reside
 - c. Because nursing is founded on the principle of social justice
 - d. The nurse wants to investigate the reasons why certain individuals and families have asthma
10. The community health nurse is looking for a way to improve heart health. Within the framework of the SDOH and upstream thinking, what contributing factor to improving heart health would the nurse most likely focus on within the community?
 - a. Vaping
 - b. Low levels of physical activity
 - c. Lack of safe places to exercise
 - d. Unhealthy diet

CHAPTER 9

Health Disparities

FIGURE 9.1 Access to reliable and affordable public transportation such as a subway, bus, or trolley can determine whether an individual obtains health care. (credit: modification of work by David Wilson/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 9.1 Health Disparities Defined
- 9.2 Race and Ethnicity Disparities
- 9.3 Gender Disparities
- 9.4 Geographical Disparities

INTRODUCTION Marinelle is a registered nurse case manager in the Population Health Management Department for a major health insurance company tasked with managing the care of Medicaid beneficiaries in a rural county in Mississippi. Medicaid is a government health insurance program that provides free or low-cost health coverage to some low-income people, families and children, pregnant individuals, older adults, and people with disabilities. It is funded by the federal government and managed by each state. The population in the county where Marinelle works has a diverse range of income levels, from low income to upper middle class. Marinelle is tasked with ensuring that clients with the highest risk factors for poor health outcomes can obtain the health care they need, which requires her to address health disparities in the population. This chapter will define health disparities and discuss the various types of health disparities in the population.

9.1 Health Disparities Defined

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 9.1.1 Define health disparities.
- 9.1.2 Discuss how health care disparities affect access to care.
- 9.1.3 Describe the Agency for Healthcare Research and Quality priority health disparities.
- 9.1.4 Recognize disparities in health as a metric for assessing health equity.

External factors beyond a person's physical and psychological attributes, such as social, economic, and environmental factors, influence health. When one or more of these factors prevent a group from having full access to the health-related resources they need, **health disparities** result. With racial and ethnic diversity increasing in the United States, addressing these disparities is essential to improving the population's health.

Recognizing Health Disparities

Healthy People 2030 defines health disparities as health differences linked to social, economic, and/or environmental disadvantages (Office of Disease Prevention and Health Promotion [ODPHP], n.d.-c). For example, Black adults are more likely to have risk factors for cardiovascular disease, and they are more than twice as likely as White adults to die from the disease (Javed et al., 2022). The CDC (2022c) defines health disparities as preventable differences in disease, injury, or violence or in opportunities to achieve optimal health experienced by socially disadvantaged racial, ethnic, and other population groups. In the United States, individuals who have experienced prejudice or bias because of their racial, ethnic, or cultural identities, without regard for their individual qualities and stemming from circumstances beyond their control, are considered **socially disadvantaged** (Business Credit and Assistance, 2023).

According to the National Institute on Minority Health and Health Disparities (NIMHD), health disparities can cause:

- Higher prevalence of disease, including earlier onset and more aggressive progression of the disease
- Increased risk of premature death from a disease or other health condition
- More prevalent unhealthy behaviors and practices
- Poorer health outcomes

[Table 9.1](#) provides some examples of health conditions and associated Healthy People 2030 goals.

Health Condition	Description	Healthy People 2030 Goals
Infant mortality	Infants born to non-Hispanic Black Americans have an infant mortality rate 2.4 times greater than non-Hispanic White Americans (U.S. Department of Health and Human Services Office of Minority Health [OMH], 2022a).	Prevent pregnancy complications and maternal deaths and improve women's health before, during, and after pregnancy
Maternal mortality	Black women are three times more likely to die from a pregnancy-related cause than White women (CDC, 2023c).	Prevent pregnancy complications and maternal deaths and improve women's health before, during, and after pregnancy
Dementia	Older Black Americans are twice as likely as older White Americans to have Alzheimer's disease or another dementia (Alzheimer's Association, 2023).	Improve health and quality of life for people with dementia, including Alzheimer's disease
Cancer	Individuals with lower incomes and education levels are more likely to get cancer and die from it compared to those who are more affluent (Singh, 2017; Tabuchi, 2020).	Reduce new cases of cancer and cancer-related illness, disability, and death

TABLE 9.1 Examples of Health Disparities (See ODPHP, n.d.-a.)

Health Condition	Description	Healthy People 2030 Goals
Obesity	Obesity rates are significantly higher in Black women and Mexican-American men when compared to other groups (Hill et al., 2017; OMH, 2022b).	Reduce overweight and obesity by helping people eat healthy and get physical activity
Smoking	Native Americans and Alaska Native men and women have a disproportionately higher rate of smoking than other groups. The same is true for individuals who are below the federal poverty level or unemployed (CDC, 2023a; CDC, 2020; Everding, 2019).	Reduce illness, disability, and death related to tobacco use and secondhand smoke
Binge drinking	Young White men are more likely to binge drink than other groups (CDC, 2022d).	Reduce misuse of drugs and alcohol

TABLE 9.1 Examples of Health Disparities (See ODPHP, n.d.-a.)

HEALTHY PEOPLE 2030

Health Equity in Healthy People 2030

Health equity is the state in which everyone has a fair and just opportunity to attain their highest level of health (CDC, 2022b). One of the [five overarching goals](https://openstax.org/r/healthareas) (<https://openstax.org/r/healthareas>) of Healthy People 2030 is to eliminate health disparities to achieve health equity and attain health literacy to improve the population's health and wellbeing. [Figure 9.2](#) provides an overview of the Healthy People 2030 goals related to health equity.

Leveraging Healthy People to Advance Health Equity

Health Equity is the attainment of the highest level of health for all people.

Achieving health equity requires valuing everyone equally with focused and ongoing societal efforts to address avoidable inequalities, historical and contemporary injustices, and social determinants of health — and to eliminate disparities in health and health care.

The infographic is titled "Leveraging Healthy People to Advance Health Equity" and includes the subtitle "Health Equity is the attainment of the highest level of health for all people." It features a central circular icon with icons representing people, data, and social determinants. Below the title, a quote discusses the need to address avoidable inequalities and social determinants of health. The main section is divided into five colored boxes:

- Objectives:** Identify priorities by browsing Leading Health Indicators and other objectives. Compare population-level progress to national targets.
- Data:** Use Healthy People data to track health disparities and inform program and policy development.
- Resources:** Find inspiration by consulting evidence-based resources to use in your community. Review Healthy People in Action stories to learn how others are addressing health equity.
- Frameworks:** Use the Healthy People 2030 framework as a model for program planning. Use the social determinants of health framework to build partnerships across sectors and communicate root causes of health disparities.
- Definitions:** Use the definitions of health equity and health disparities to promote a shared understanding and identify areas for collaborative action to improve health for all.

Leveraging Healthy People to Advance Health Equity

Healthy People 2030

FIGURE 9.2 This infographic displays the Healthy People 2030 goals for advancing health equity. (credit: “Leveraging Healthy People to Advance Equity” by U.S. Department of Health and Human Services, Public Domain)

The populations that most often experience health disparities include racial and ethnic minorities, people with lower socioeconomic status, underserved rural communities, and sexual and gender minorities (NIMHD, 2023). Each of these populations will be discussed in detail later in this chapter. [Table 9.2](#) describes individual health determinants and their effect on outcomes (NIMHD, 2023).

Health Determinant	Description
Individual behaviors	The choices one makes have a direct impact on their health outcomes. For example, health-promoting behaviors such as getting regular exercise and eating a nutritious diet may lead to positive health outcomes. In contrast, behaviors that lead to negative health outcomes include smoking tobacco and driving while intoxicated.
Lifestyles	Unhealthy lifestyles secondary to individual health behaviors lead to a greater prevalence of negative health outcomes, such as those related to disease processes.
Social responses to stress	Individuals without coping skills to deal with stress tend to have less-than-optimal health outcomes, such as the presence of chronic diseases such as diabetes and hypertension.
Biological processes	Biology presents unavoidable risk factors for individuals related to health outcomes, such as inheriting certain diseases from parents like diabetes or hypertension.
Genetics	Genetics relates to a branch of biology that deals with heredity and genes passed from parent to child. Genetics are factors that cannot be altered by an individual, who can only alter behavioral risk factors such as smoking or unhealthy eating.
Epigenetics	Epigenetics refers to how behaviors and environment cause changes that impact how genes work. For example, an individual who lives in a home where other family members smoke may have an increased risk for diseases such as cancer even if the individual's genetics are not associated with cancer.
Physical environment	What individuals are exposed to where they reside has a direct impact on their health outcomes, such as exposure to pollutants in either urban or rural areas.
Sociocultural environment	Sociocultural environment relates to the combination of who individuals interact with and what their cultural beliefs, habits, and traditions are. For example, cultural norms associated with various foods can impact health outcomes. When a family is accustomed to eating high volumes of fried foods or high-carbohydrate foods, there is an increased risk for chronic diseases such as obesity, diabetes, and hypertension.
Interactions with the health care and other systems	When individuals interact negatively with the health care system, the likelihood that they will continue to utilize that particular service is limited, thus leading to poor health outcomes.

TABLE 9.2 Health Determinants and Health Disparities

CONVERSATIONS ABOUT CULTURE

Minority Health Disparities | Michelle's Story

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-1-health-disparities-defined>\)](https://openstax.org/books/population-health/pages/9-1-health-disparities-defined)

This video by John Hopkins Medicine features Michelle Simmons, a West Baltimore resident who describes the impact of health disparities on her family and her community and her efforts to reverse their negative effects.

Watch the video, and then respond to the following questions.

1. What are some of the health disparities Michelle describes in the video, and how might they negatively affect her health and her community's health?
2. What are some of the root causes of health disparities discussed in the video?
3. What choices did Michelle need to make to prioritize her health?

As discussed in [Social Determinants Affecting Health Outcomes](#), the social determinants of health (SDOH) are the environmental conditions that affect health, functioning, and quality of life (ODPHP, n.d.-b). Healthy People 2030

groups these determinants into five categories: economic stability, education, health care access and quality, neighborhoods, and social and community context. Health determinants influence health outcomes. For example, Black women experience lower survival rates related to breast cancer than their White counterparts (NIMHD, 2023). This health disparity is most often related to Black women's lower rates of breast cancer screening and greater chance of a late-stage diagnosis. Poverty also contributes to this disparity as individuals with lower income levels also have lower rates of breast cancer screening and overall poorer health outcomes regardless of their race (Yedjou et al., 2019). See [Structural Racism and Systemic Inequities](#) and [Social Determinants Affecting Health Outcomes](#) for more information on the implications of race and poverty on health outcomes.

SOCIAL DETERMINANTS OF HEALTH: WHAT ARE THEY AND HOW DO THEY IMPACT THE HEALTH OF POPULATIONS?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-1-health-disparities-defined>\)](https://openstax.org/books/population-health/pages/9-1-health-disparities-defined)

This video explains the foundational impact of structural racism, social determinants of health and their impact on historically marginalized populations, and steps necessary to achieve health equity in affected communities.

Watch the video, and then respond to the following questions.

1. In the video, the narrator uses the story of sick fish to show the tendency of society to blame the individual for their health condition rather than considering the outside determinants of health. Describe an example of this from your own community.
2. The narrator describes three strategies for identifying health disparities—pay attention, be aware, and create strategies. In the example from your community, describe how this approach could be used to identify and address the disparities.

Health Care Disparities and Access to Care

While health disparities indicate different health-related outcomes among groups, **health care disparities** are differences among groups related to health care access and use. When people have full access to health care, they have the timely use of the health services they need to achieve optimal health outcomes. Access to health care consists of four key components (Agency for Healthcare Research and Quality [AHRQ], 2023):

- Coverage—Health insurance facilitates entry into the health care system.
- Services—Having a regular source of care is associated with receiving recommended screenings.
- Timeliness—Health care must be provided when it is needed.
- Workforce—Access to health care depends upon the availability of qualified and culturally competent providers.

Insurance Coverage and Related Socioeconomic Factors

Several studies have identified correlations between having health insurance coverage and positive health outcomes (AHRQ, 2022). Collectively, research has shown that insured individuals have increased financial security, improved access to primary care and screenings for health conditions, and improved compliance with medication regimes and that they are less depressed and perceive themselves to be healthier.

The Affordable Care Act (ACA) of 2010 expanded both affordable health insurance options for Americans and the number of people eligible for Medicaid, and it supported innovation in health care delivery to lower health care costs (U.S. Department of Health and Human Services [HHS], 2022a). As a result, more than 20 million Americans gained access to health insurance (HHS, 2022b). In addition, the ACA established protections for preexisting conditions and mandated coverage for essential health benefits (HHS, 2022b).

Despite the gains made by the ACA, many Americans remain uninsured. Disparities in health insurance coverage exist primarily among individuals under age 65, as almost all adults 65 and older are covered by Medicare (AHRQ, 2022). Individuals under age 65 can be covered by private health insurance or other government-sponsored plans, such as Medicaid or a military health plan. Most of the remaining uninsured individuals are in families with at least one employed worker (Garfield et al., 2019). Not all employers offer health insurance to their employees. For example, agricultural, construction, and service workers are more likely to work for businesses that do not provide employer health plans. Also, part-time workers may not be eligible for coverage. Lastly, some workers are eligible to

join an employer plan but cannot afford the premiums.

People in low-income households, minority communities, and some urban and rural communities are less likely to have health insurance. For example, Non-Hispanic American Indian or Alaska Native and Hispanic groups are less likely to be insured (AHRQ, 2022). Additionally, how Medicaid is administered from state to state may create differences in health care treatment and options between beneficiaries according to the state in which they live. For example, one state may have a higher threshold to determine who is eligible for Medicaid benefits than another state. Individuals who live in states with higher eligibility requirements but who have lower incomes will face limitations to health care access if they cannot afford private health insurance or pay out of pocket for their care.

Differences in income levels result in major differences in health outcomes. For example, individuals with limited income tend to have higher incidences of chronic diseases such as diabetes and hypertension. These individuals also have limited access to health care services because of related logistical issues. For example, they are more likely to lack reliable or timely transportation to and from a doctor's office or medical clinic.

Availability of Health Care Services and Providers

To meet the population's health needs, the health care delivery system must have adequate infrastructure and resources (AHRQ, 2022). Staffing shortages and the location and capacity of health care facilities are key concerns. The number of health care workers in hospitals and long-term care facilities has decreased since January 2020, and almost 63 percent of U.S. counties have been designated as primary care professional shortage areas. Among these areas, rural counties are disproportionately affected. Living near primary care services can increase clients' likelihood of receiving preventative care and treatment for a chronic health condition (Figure 9.3) (AHRQ, 2022). Further disadvantaging clients living in rural areas, 135 rural hospitals closed between 2010 and 2020 (AHRQ, 2022). These closures force clients to travel farther to receive hospital-related services.

FIGURE 9.3 Lack of access to a health care provider is often a barrier for clients living in rural areas or in urban areas where reliable transportation is an issue. This photo shows a provider examining a client in a COSSMA, Inc. clinic in Cidra, Puerto Rico, that was built with USDA Rural Development funds to offer the community medical, dental, and mental health services. (credit: "Opened in 2008, this COSSMA facility in Cidra, PR, is one of six health clinics on Puerto Rico built with USDA Rural Development funds" by Preston Keres/USDA/Flickr, Public Domain)

Priority Health Disparities

For over 20 years, the Agency for Healthcare Research and Quality (AHRQ) has monitored health care quality and disparities to identify opportunities for improvement. In the [2022 National Healthcare Quality and Disparities Report](https://openstax.org/r/ahrqnqrdr) (<https://openstax.org/r/ahrqnqrdr>) (NHQDR), the agency identified four priority issues: maternal health, child and adolescent mental health, substance use disorder, and oral health.

Maternal Health

According to the NHQDR, the United States has the highest maternal mortality rate among industrialized countries. The rate continues to increase, with higher mortality rates among marginalized racial and ethnic groups. The NHQDR notes other disparities relative to prenatal care. Hispanic, American Indian/Alaska Native, Black, and Native Hawaiian/Pacific Islander clients are less likely than White and non-Hispanic White clients to receive prenatal care. Between 2016 and 2019, rates of severe maternal morbidity, eclampsia/preeclampsia, severe postpartum hemorrhage, and venous thromboembolism or pulmonary embolism increased overall, with disparities noted among racial and ethnic groups. Between 2017 and 2019, pregnancy-related mortality ratios (per 100,000 births) differed significantly among groups (CDC, 2023b). The rate for Non-Hispanic Native Hawaiian or Other Pacific Islander was the highest at 62.8, followed by Non-Hispanic Black at 39.9, Non-Hispanic American Indian or Alaska Native at 32, Non-Hispanic White at 14.1, Non-Hispanic Asian at 12.8, and Hispanic at 11.6 (CDC, 2023b). Plans to address maternal health disparities include extending postpartum coverage, investing in rural maternal health services, creating and expanding a more diverse maternal health workforce, and creating stronger workplace protections for caregivers (AHRQ, 2022).

I KNOW MY BODY

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-1-health-disparities-defined>\)](https://openstax.org/books/population-health/pages/9-1-health-disparities-defined)

In this video, tennis player Serena Williams describes her postpartum experience with life-threatening complications despite presumably having access to quality health care.

Watch the video, and then respond to the following questions.

1. What, if anything, surprises you about Ms. Williams's story?
2. What contributed to the delay in the health care providers' recognition and treatment of her condition?
3. What can you take from this story that you can apply to your practice?

Child and Adolescent Mental Health

Mental health issues are widespread. Almost 20 percent of children and adolescents ages 3–17 in the United States have a mental, emotional, developmental, or behavioral disorder (AHRQ, 2022). However, the increasing mental health issues among this age group do not correspond to an increase in mental health service access and utilization. Recent initiatives to address this issue include the designation of “988” as the universal number for the Suicide and Crisis Lifeline (FCC, 2022). [Caring for Vulnerable Populations and Communities](#) discusses the mental health crisis in more detail.

Substance Use Disorder

Substance use disorders (SUD) are a costly, pervasive health concern. Defined as the misuse of illicit drugs, prescription drugs, and/or alcohol, these conditions negatively affect health, and they cost the U.S. economy billions of dollars. There are significant barriers and disparities related to preventing and treating SUD. Less than 50 percent of people treated for SUD complete treatment, with Non-Hispanic Native Hawaiian/Pacific Islander individuals having the lowest percentage of completion among this group (AHRQ, 2022). Rates of drug overdose deaths involving opioids increased between 2018 and 2020. The largest increases were noted among non-Hispanic Black people in large urban areas. Multiple initiatives, including expanding access to naloxone and to evidence-based treatment, aim to address these issues (AHRQ, 2022). [Caring for Vulnerable Populations and Communities](#) discusses SUD in more detail.

Oral Health

Oral health is essential for good nutrition, quality sleep, and school/work attendance and performance (AHRQ, 2022). Poor oral health is associated with chronic health conditions. Oral health care has improved for children but not for adults. Two indicators tracked to measure the quality of oral health care delivery in the United States include the prevalence of untreated dental caries and emergency department visits for dental conditions. Key interventions for improving oral health include fluoridating the public water supply, reducing financial barriers to dental services, and improving proximity to dental care. NHQDR data show gains among children and adolescents. Disparities have decreased between Asian, Black, Hispanic, and multiracial groups and White groups and between low- and high-

income households. A key reason for the improvement is the inclusion of dental benefits in Medicaid and CHIP programs. Dental care for adults is generally not included in their health insurance coverage.

Measuring Health Disparities

After health disparities are identified, assessing and monitoring their severity and impact is essential. Researchers and policymakers have identified relevant metrics that correlate with the effects of health disparities. These can be used to track the population's health and the impact of the disparity as well as to reflect the effectiveness of interventions. Ultimately, addressing health disparities leads to health equity, which Healthy People 2030 defines as the attainment of optimal health for everyone (ODPHP, n.d.-b). As discussed in [The Health of the Population](#), the AHRQ (2022) tracks several metrics across racial and ethnic groups to monitor the effects of health disparities including:

- Life expectancy—In 2020, life expectancy in the United States decreased for the first time due to the COVID-19 pandemic. This decline was more remarkable for Hispanic and non-Hispanic Black groups than for non-Hispanic White groups.
- Leading causes of death—In 2020, the leading causes of death in the United States were heart disease, cancer, COVID-19, and unintentional injuries. Certain racial and ethnic groups have increased risks for these conditions.
- Years of potential life lost (YPLL)—This measures premature death. It adjusts mortality statistics for age at death and estimates the average time the person would have lived. Death from unintentional injuries is the leading cause of YPLL across the age spectrum. In 2020, heart disease, liver disease, and diabetes were rising rapidly as leading causes of YPLL.

Healthy People 2030 monitors progress on all the identified objectives for any differences among age groups and acknowledges that measuring health disparities is fundamental to addressing health equity (ODPHP, n.d.-b). [The Health of the Population](#) discusses Healthy People 2030 in more detail.

9.2 Race and Ethnicity Disparities

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 9.2.1 Identify contributing factors that influence race and ethnicity disparities.
- 9.2.2 Recognize internal and external system processes and structures that perpetuate racism and other forms of discrimination within health care.

As discussed in [Structural Racism and Systemic Inequities](#), racism has physical, behavioral, and emotional effects (Javed et al., 2022). Accordingly, racial and ethnic minorities are most often impacted by health disparities. According to the AHRQ (2022), racial and ethnic minority communities have outcomes similar to those of White communities for fewer than half of all quality-of-care measures.

Characteristics of Minority Groups

Minority health refers to the characteristics and attributes of health that are specific to a racial or ethnic minority group who are socially disadvantaged in part because of racist or discriminatory acts and are underserved in health care (NIMHD, 2023). These characteristics and attributes are often secondary to discrimination, racism, and genetics. For example, Black individuals tend to have higher incidences of hypertension than their White counterparts. The U.S. Office of Management and Budget identifies the following as minority populations:

- American Indian or Alaska Native
- Asian
- Black or African American
- Hispanic or Latino American
- Native Hawaiian and Pacific Islander (OMB, 1997).

The National Institute on Minority Health and Health Disparities has developed a framework (see [Figure 9.4](#)), that identifies health determinants relevant to understanding minority health (NIMHD, 2023). The model depicts the influences on minority health at the individual, interpersonal, community, and societal levels throughout the

lifespan.

		Levels of Influence*			
		Individual	Interpersonal	Community	Societal
Domains of Influence (Over the Lifecourse)	Biological	Biological Vulnerability and Mechanisms	Caregiver-Child Interaction Family Microbiome	Community Illness Exposure Herd Immunity	Sanitation Immunization Pathogen Exposure
	Behavioral	Health Behaviors Coping Strategies	Family Functioning School/Work Functioning	Community Functioning	Policies and Laws
	Physical/Built Environment	Personal Environment	Household Environment School/Work Environment	Community Environment Community Resources	Societal Structure
	Sociocultural Environment	Sociodemographics Limited English Cultural Identity Response to Discrimination	Social Networks Family/Peer Norms Interpersonal Discrimination	Community Norms Local Structural Discrimination	Social Norms Societal Structural Discrimination
	Health Care System	Insurance Coverage Health Literacy Treatment Preferences	Patient-Clinician Relationship Medical Decision-Making	Availability of Services Safety Net Services	Quality of Care Health Care Policies
Health Outcomes		 Individual Health	 Family/ Organizational Health	 Community Health	 Population Health

National Institute on Minority Health and Health Disparities, 2018
 *Health Disparity Populations: Racial and Ethnic Minority Groups (defined by OMB Directive 15), People with Lower Socioeconomic Status, Underserved Rural Communities, Sexual and Gender Minority Groups, People with Disabilities
 Other Fundamental Characteristics: Sex and Gender, Disability, Geographic Region

FIGURE 9.4 The NIMHD Minority Health and Health Disparities Research Framework includes the factors necessary to understand and promote minority health and reduce or eliminate health disparities. (credit: “National Institute on Minority Health and Health Disparities Research Framework” by U.S. Department of Health and Human Services, Public Domain)

Income Inequality

According to the U.S. Census Bureau, in 2021, the gap between the top 10 percent of households with an annual income of \$211,956 and the bottom 10 percent of households with a yearly income at or below \$15,660 increased by 4.9 percent from 2020 (Semega & Kollar, 2022). The household income at the top of the range did not increase significantly. Instead, the spread between the middle to lower incomes increased, meaning the lowest-income households experienced a greater income decline than middle-income households (Semega & Kollar, 2022).

Minority groups are disproportionately represented in these statistics. Pay for ethnic minority individuals is significantly less than that of their non-minority White people. Black and Hispanic adults continue to earn less than White or Asian adults. In 2020, median household income was approximately \$46,000 for Black and \$55,500 for Hispanic workers compared to \$75,000 and \$95,000, respectively, for White and Asian workers (U.S. Department of the Treasury, 2022). These limited incomes make it more difficult for ethnic minorities to afford health care services, which in turn makes it more difficult to stay healthy and manage health conditions.

Environmental Factors

Approximately 24 million people in the United States live in impoverished/disadvantaged neighborhoods (Christie-Mizell, 2022). These are neighborhoods that are affected by high levels of poverty, contain dilapidated buildings and structures, have a disproportionate number of female-headed households, and have high unemployment and crime rates. Racial and ethnic minorities are more likely to live in these areas. Census data show 20.9 percent of Black Americans live in these neighborhoods compared with 4.3 percent of White Americans (Christie-Mizell, 2022). Accordingly, living in these areas disproportionately exposes minority populations to poor environmental factors including unsanitary living arrangements, increased risk of violence, or limited access to grocery stores selling healthy foods. Research has confirmed that these residents have higher rates of chronic disease and experience poorer health outcomes (Christie-Mizell, 2022).

Systemic Discrimination or Exclusion

Social drivers such as racism, sexism, ableism, classism, and homophobia exacerbate inequalities, with minorities having a disadvantage. Unfortunately, racism and other social drivers are deeply entrenched in societal and cultural norms. Systematic discrimination and exclusion result in limited access to community resources such as public transportation, quality education, and employment opportunities. [Structural Racism and Systemic Inequities](#) and

[Caring for Vulnerable Populations and Communities](#) discuss this topic in more detail.

Systemic Discriminatory Practices

As discussed in [Structural Racism and Systemic Inequities](#), racism is one of the most common contributing factors to health disparities for ethnic minorities (Braveman et al., 2022). It is frequently systemic and structural, making it difficult to recognize. Systemic and structural racism are forms of racism that are pervasively and deeply embedded in systems, laws, written or unwritten policies, and entrenched practices and beliefs that produce, condone, and perpetuate widespread unfair treatment and oppression of people of color, with adverse health outcomes. Examples of systemic and structural racism include:

- residential segregation,
- unfair lending practices,
- barriers to home ownership and accumulating wealth,
- public schools' dependence on local property taxes,
- environmental injustice,
- biased policing and sentencing of men and boys of color, and
- voter suppression policies.

Systemic and structural racism are part of the fabric of society. To address their effects, it is essential to acknowledge systemic and structural racism and to take mutually reinforcing actions in different parts of the community (Braveman et al., 2022).

THE ROOTS OF HEALTH INEQUITIES

Race, Racism, and Cardiovascular Health

The effects of historical practices that aimed to facilitate home ownership for White populations and discourage ownership for Black populations continue today. For example, the Federal Housing Administration created maps indicating mortgage insurance risk. Areas with a high Black population were colored red, indicating these areas were high-risk areas for insurance. This practice, known as redlining, essentially prevented Black Americans from being able to own homes and become economically stable. Redlining consigned populations of color to live in under-resourced and unsafe neighborhoods. Living in disadvantaged neighborhoods, a social determinant of health, is linked to poor health. Javed et al. (2022) found that neighborhood disadvantage increases the risk of cardiovascular disease and poor cardiovascular disease outcomes for the inhabitants. [Structural Racism and Systemic Inequities](#) discusses redlining in more detail.

(See Javed et al., 2022.)

The Effect of COVID-19 on Health Disparities

The COVID-19 pandemic further exacerbated racial disparities. According to the CDC (2021), COVID-19 had a disproportionate impact on individuals from certain racial and ethnic groups. For example, individuals from minority communities experienced a higher risk for infection, more hospitalizations, and more deaths related to COVID-19 when compared to their White counterparts. Such disparities occurred in each region of the United States. A mistrust of the U.S. health care system, discussed in [Demographic Trends and Societal Changes](#), was a key factor in minorities having increased infection rates. For example, racial and ethnic minority groups, particularly Black Americans, did not readily trust the COVID-19 vaccine and often delayed receiving it (Na et al., 2023). This, coupled with delays in and the lack of access to COVID-19 testing and the presence of certain comorbidities such as diabetes and asthma, led to higher rates of infection and, ultimately, death related to the disease (Na et al., 2023). In many instances, members of minority populations did not seek care until their disease was more advanced, thus necessitating the need for hospitalization and increasing death rates (Shearn & Kockrow, 2023). In addition to the disparities associated with health care, minority populations were disproportionately represented in “frontline” and lower-paid jobs, such as health care, food service, and other jobs that could not be performed remotely and placed them in close proximity to others (OECD, 2022). Some of these workers lost their jobs, and others continued to work in person and had a higher risk of contracting COVID compared to workers with white-collar jobs who could work remotely. [Structural Racism and Systemic Inequities](#) for a more detailed discussion.

HOW COVID-19 IS HIGHLIGHTING RACIAL DISPARITIES IN AMERICANS' HEALTH

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-2-race-and-ethnicity-disparities>\)](https://openstax.org/books/population-health/pages/9-2-race-and-ethnicity-disparities)

This video discusses how COVID-19 has exacerbated health disparities associated with race in the United States. It addresses how health outcomes are worse for Black people in the United States when compared to their White counterparts and discusses how the economy impacts health outcomes.

Watch the video, and then respond to the following questions.

1. How did you feel watching the video and listening to the stories?
2. How does one's race impact their health outcomes?
3. What actions can the community health nurse take to address racial health disparities?

9.3 Gender Disparities

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 9.3.1 Describe how gender affects health outcomes.
- 9.3.2 Assess influencing factors contributing to gender disparities.
- 9.3.3 Discuss health disparities faced by the LGBTQIA+ community.

Research shows men and women experience different health outcomes beyond what would be expected for sex-specific conditions and treatments. Women and members of the LGBTQIA+ community frequently experience poorer health outcomes and face more barriers to health care access.

Concepts Related to Sex and Gender

The terms *sex* and *gender* are sometimes used interchangeably. While they are interrelated terms, they have distinct differences. **Sex** refers to the physiological and biological characteristics of males and females. **Gender** refers to male and female characteristics that are socially constructed (World Health Organization [WHO], 2023). **Gender identity** refers to a person's internal experience and belief of gender, which may or may not correspond to their physiology or designated sex at birth (WHO, 2023). LGBTQIA+ is used to refer collectively to lesbian, gay, bisexual, transgender, queer/questioning, intersex, asexual/aromantic/agender, and other related groups. The terms used to describe these groups are fluid and may change frequently, and not all people feel that they are represented by a specific term.

Physical differences can result in the development of sex-specific conditions. For example, each sex has a different reproductive system and corresponding reproductive diseases. Gender health disparities appear to encompass both sex and gender characteristics as biological, psychological, and social mechanisms intertwine to affect health outcomes in those with long-term disabling conditions (Thakral et al., 2019).

GENDER DISPARITIES IN HEALTH CARE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-3-gender-disparities>\)](https://openstax.org/books/population-health/pages/9-3-gender-disparities)

In this video, women share their experiences of health care bias that delayed their diagnoses and treatments.

Watch the video, and then respond to the following questions.

1. What are the trends or consistencies in the cases described in this video?
2. What can nurses learn from these stories that they can incorporate into their practice?

Gender Differences

Gender norms are social and cultural principles that influence ideas on how different genders are supposed to behave in society. Such norms are often harmful. For example, gender stereotypes, or generalized preconceptions about what roles or traits should be performed by men and women, often limit their potential and create inequality. Society may also assign rank or status according to gender (i.e., men have a higher standing than women), which

causes inequalities between genders that intersect with other social and economic inequalities. Discrimination based on gender often crosses, or intersects, with other societal factors such as ethnicity, disability, socioeconomic status, age, geographic location, gender identity, and sexual orientation (WHO, 2023). This is known as **intersectionality**, a concept that considers how multiple disadvantages can interact with clients individually and reflect the inequities and injustices at the systems level. Sexism, racism, classism, colonialism, heterosexism, and ableism are a few of the structures that result in systems-level oppression and privilege (Crenshaw, 1991).

Globally, gender norms negatively affect girls and women more than boys and men (Office of the High Commissioner for Human Rights [OHCHR], 2023). For example, over 575 million girls reside in countries where their basic rights related to education, health, and safety are violated as a consequence of inequitable gender norms (Save the Children, 2023). According to the OHCHR, gender stereotypes and discrimination, intersecting with other social and economic stereotypes, are particularly detrimental to women from minority or Indigenous groups, women with disabilities, women from lower caste groups or with lower economic status, and migrant women (OHCHR, 2023).

Boys and men may also be negatively affected by gender norms, particularly those that emphasize rigid notions of masculinity. For example, some gender norms may encourage young men to engage in risky practices such as smoking, unprotected sexual behavior, and alcohol use and abuse, and it may make them less likely than women to seek medical attention (WHO, 2023). Some conceptions of masculinity lead males to commit violence against women and make men subject to violence perpetrated by other men. These pressures may lead some individuals to develop mental health issues (WHO, 2023).

Individuals who identify as gender diverse or transgender also experience negative consequences related to gender. Gender-diverse individuals do not conform to conventional gender norms of being a man or a woman, or they may not “place themselves in the male/female binary” (OHCHR, 2023, para 1). Individuals who are transgender identify with a different sex than the one assigned to them at birth. Globally, both groups experience marginalization, exclusion, violence, discrimination, and other human rights violations related to their gender identities (OHCHR, 2023).

Gender affects people’s experiences with and access to health care. How health services are organized and provided may either enable a person’s access to health care services, information, and support or hinder it (WHO, 2023). Women’s health and well-being is placed at risk because of gender inequality and discrimination. Women more frequently face barriers to accessing health information and services than men. Throughout the world, women face restrictions on movement in the health care system, lack of access to decision-making power, low health literacy rates, discriminatory attitudes of communities and health care providers, and a lack of training among health care providers specific to the health care needs and challenges they face (WHO, 2023).

Findings from a recent survey on women’s experiences with the U.S. health care system are consistent with the WHO’s conclusions. For example, 29 percent of U.S. women aged 18–64 who were surveyed reported their doctor dismissed their concerns, and another 15 percent reported their provider did not believe they were telling the truth (Long et al., 2023). Among survey participants aged 40–64, only 35 percent reported their health care provider discussed what to expect with menopause (Long et al., 2023). In another study, researchers used data from the CDC Behavioral Risk Factor Surveillance System (BRFSS) to study differences between males’ and females’ ability to access medical care for atherosclerotic cardiovascular disease (ASCVD). They found that women were more likely to report a delay in accessing health care and an inability to see a health care provider or take prescribed medications due to cost than men (Daher et al., 2021).

Global health-related challenges females face include (WHO, 2023):

- Higher rates of unintended pregnancies for women and girls.
- Greater risk of developing diseases and conditions such as malnutrition, lower vision, and respiratory infections.
- Greater risk of experiencing elder abuse than older males.
- Higher rates of violence directed toward them when compared to males, which includes sexual and physical violence. Approximately one in three women worldwide have experienced either physical and/or sexual intimate partner violence or non-partner sexual violence in their lifetime.
- In some developing countries, women experience female genital mutilation and early and forced marriage.

▶ HOW THE GENDER GAP IN CLINICAL DRUG TRIALS IS AFFECTING WOMEN

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-3-gender-disparities>\)](https://openstax.org/books/population-health/pages/9-3-gender-disparities)

Decades ago, the United States took an important step toward addressing gender disparities in medicine. In 1986, the National Institutes of Health (NIH) established a policy requiring that women be included as subjects of clinical research. The following year, the Food and Drug Administration (FDA) began requiring pharmaceutical companies to demonstrate medication safety and effectiveness by sex, age, and race (Office on Women's Health, 2020). Despite these policy gains, more work is needed; this video offers a glimpse of the impact of the persistent gender gap in today's clinical drug trials.

Watch the video, and then respond to the following questions.

1. Beyond the immediate physical effects the women in the video experienced, what other consequences could these women face?
2. Knowledge gaps in medical research are a form of gender bias in health care. What other forms of gender bias against women exist in health care?

Special Considerations for the LGBTQIA+ Population

Research shows that the LGBTQIA+ population experiences poorer health outcomes compared to the cis-heterosexual population. In a systematic review of the literature, Medina-Martinez et al. (2021) found that as compared to the cis-heterosexual population, this community experiences higher rates of mental health problems, substance misuse, and suicide. They also found that certain cancers, including colon, liver, breast, ovarian, and cervical, are more prevalent among lesbian and bisexual women. Gay and bisexual men have higher rates of sexually transmitted infections, including HIV, as well as increased rates of anal, prostate, testicular, and colon cancers (Medina-Martinez et al., 2021). Compared with the general population, individuals who are transgender experience a higher prevalence and earlier onset of disabilities, more chronic health conditions, and higher rates of health problems related to AIDS, substance use, mental illness, and sexual and physical violence (Medina et al., 2021). For children and adolescents who identify as lesbian, gay, bisexual, transgender, questioning, or queer (LGBTQ), the risks of suicidal thoughts and behaviors is higher (AHRQ, 2022).

Along with the disease risks for members of the LGBTQIA+ population, there are the issues of homophobia, stigma, and discrimination regarding their identity (CDC, 2022c). Limited access to culturally appropriate and orientation-appropriate services can hinder treatment. Finally, members of this group may be fearful about talking about their gender identity and sexual orientation. LGBTQIA+ people face barriers when trying to access health care, including negative and discriminatory experiences with health care workers (Medina-Martinez et al., 2021). Transgender people often experience verbal and physical abuse, hostility, and refusal of care during their interactions with the health care system or with individual health care providers (Medina et al., 2021). See [Caring for Vulnerable Populations and Communities](#) for more information on health care challenges related to the LGBTQIA+ population.

UNFOLDING CASE STUDY

Part A: Addressing Disparities

Read the scenario, and then answer the questions that follow.

As part of her role as a registered nurse case manager for Medicaid clients, Marinelle works with pregnant clients to coordinate their prenatal care. These clients are part of a group that has been identified as high risk for pregnancy-related complications. For the past few months, Marinelle has tracked her clients' prenatal appointments and detects a trend in missed appointments. Most clients who miss appointments live in the same area of the county. It is a small rural neighborhood located in the vicinity of an abandoned factory. All the clients are Black women.

1. Which of the following factors should the nurse consider as most likely contributing to the clients' poor pregnancy-related outcomes?
 - a. Genetics

- b. Biological factors
 - c. Cultural environment
 - d. Physical environment
2. One aspect of health care access is clients' ability to attend scheduled appointments. Which of the following factors is most likely to facilitate clients' ability to access health care?
- a. Having a chronic disease
 - b. Having adequate insurance coverage
 - c. Having strong social support
 - d. Having the ability to take time off work for appointments
-

9.4 Geographical Disparities

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 9.4.1 Examine how health status and health outcomes vary by geographical location.
- 9.4.2 Explain how a zip code influences health.
- 9.4.3 Assess contributing factors leading to geographical disparities.

Throughout history, **geography** has influenced the health and well-being of communities in various ways. The environment affects the nation's food supply and plays a role in disease transmission. Geography also affects health care delivery and health outcomes of the population. **Geographical disparities** refer to the differences in health care access and outcomes based upon where an individual lives. Disparities are often discussed in terms of rural or urban living; however, there can be health disparities between populations of different states.

The U.S. Census Bureau defines urban and rural areas based on population size and density. For an area to be considered urban, it must encompass at least 2,000 housing units or have a population of at least 5,000. Rural areas are considered all population, housing, and territory not included in an urban area (U.S. Census Bureau, 2023). Most counties in the United States have a mix of rural and urban populations (U.S. Department of Agriculture [USDA], 2023). According to the 2020 census, 80 percent of the U.S. population live in urban areas, while 20 percent live in rural areas (U.S. Census Bureau, 2022).

Factors Influencing Population Health Related to Location

The 2022 National Healthcare Quality and Disparities Report compares health care quality and disparities scores on over 100 health-related measures among states (AHRQ, 2022), with the following results:

- Best overall health care quality: Maine, Massachusetts, New Hampshire, Pennsylvania, Rhode Island, Iowa, Minnesota, North Dakota, Wisconsin, Colorado, and Utah
- Lowest overall health quality: Alaska, Arizona, California, Montana, Nevada, New Mexico, Wyoming, Washington D.C., Georgia, Mississippi, Oklahoma, Texas, and New York
- Fewest racial and ethnic disparities overall: Arizona, Hawaii, Idaho, Oregon, Washington, Arkansas, Kentucky, Virginia, West Virginia, Kansas, and New Jersey
- Most racial and ethnic disparities overall: Connecticut, Massachusetts, New York, Pennsylvania, Illinois, Minnesota, Ohio, Washington D.C., North Carolina, and Texas

There are several reasons for variations among states in terms of health care quality and disparities (AHRQ, 2022). First, health policy can vary by state. Some states may offer more health-related resources or social programs than others. Health care delivery infrastructure can vary by state. For example, some states regulate the construction of new hospitals and other treatment facilities more closely. Finally, disease prevalence can vary by state. For example, diabetes, arthritis, and chronic obstructive pulmonary diseases are more prevalent in eastern U.S. states (Raghupathi & Raghupathi, 2018). Diabetes, in particular, is influenced by cultural, behavioral, and environmental factors associated with certain geographical areas (Zang et al., 2021); it is more prevalent in the southeastern and Appalachian portions of the United States (CDC, 2022a). Asthma is another disease with some geographical trends, although a lot of variation related to population density and demographics can exist in a particular state. The Northeast Mid-Atlantic asthma belt (from Greensboro, North Carolina, to Boston, Massachusetts) has been shown to

have a higher prevalence of asthma possibly due to poverty, poor air quality, and less access to specialists (Pate et al., 2021). The Asthma and Allergy Foundation of America (2018) identified a second group of states with an increased prevalence of asthma and associated ED visits and deaths. The Ohio-Lake Erie asthma belt spans from Louisville, Kentucky, to Detroit, Michigan.

Health and related outcomes vary not only by state, but also by county, town, or zip code. Research has linked zip codes to health outcomes (Holmes et al., 2018). For example, people living in neighborhoods with limited access to healthy foods and safe areas to exercise are at higher risk for health problems.

ZIP CODES AND LIFE EXPECTANCY

This interactive site [What makes a long life? \(https://openstax.org/r/rwjf\)](https://openstax.org/r/rwjf) from the Robert Wood Johnson Foundation provides a tool that illustrates the differences between life expectancy based on a person's address. Enter a street address or zip code of interest to see how the life expectancy of people living at that location compares to others in the county, state, and nation, and then answer the following questions.

1. What address or addresses did you enter?
2. Are the findings consistent with what you expected?
3. Among the locations you searched, did you discover significant differences among nearby locations? If so, what were they?

Factors Influencing Population Health Related to Population Density

Some of the most common geographical disparities exist between those who live in rural areas and those who live in urban areas. Individuals living in rural areas face geographic isolation, lower socioeconomic status, higher rates of health risk behaviors, limited access to health care specialists and subspecialists, and limited job opportunities (Rural Health Information Hub [RHIH], 2023). Additionally, residents who live in rural areas are less likely to be employed by organizations that provide health insurance coverage. If individuals living in rural areas also live below the poverty level, they are less likely to be covered by Medicaid (RHIH, 2023). Rural health disparities are often caused by access to health care and public health services, socioeconomic status, health behaviors, and health insurance status. Rural Americans are at a greater risk of death from heart disease, cancer, unintentional injury, chronic lower respiratory disease, and stroke than Americans who live in urban areas (RHIH, 2022). Rural residents tend to be older and more obese and to have more health problems than urban residents. They are more likely to smoke cigarettes and are less likely to use seat belts (Figure 9.5) (FDA, 2021). Table 9.3 presents relevant factors affecting rural health outcomes.

FIGURE 9.5 National efforts to promote the use of seat belts include public information campaigns, such as this valentine-themed graphic from the National Transportation and Safety Board. Studies have shown that residents of rural areas are less likely to wear seat belts than

residents of urban areas, which is one factor contributing to higher traffic fatality rates in rural areas (CDC, 2017). (credit: “NTSB Valentine” by National Transportation Safety Board/Flickr, Public Domain)

Factor	Discussion
Access to health care and public health services	<ul style="list-style-type: none"> Rural areas tend to have shortages of quality physician offices and other health-related resources. Health care organizations in rural areas have difficulty recruiting health care providers. Limited access to health care providers and services equates to poor health outcomes for individuals.
Socioeconomic status	<ul style="list-style-type: none"> Individuals living in rural areas tend to have higher rates of poverty compared to their urban counterparts. Job opportunities tend to be scarcer in rural areas than in urban areas. High poverty equates to limited health care access, leading to poor health outcomes.
Health insurance status	<ul style="list-style-type: none"> The highest prevalence of uninsured individuals is among those living in rural areas. Higher poverty rates in these areas limit residents' ability to pay for health insurance coverage. Depending on the policies in the state in which they reside, they may not qualify for Medicaid. Lack of adequate health insurance equates to limited access to care, leading to less-than-optimal health outcomes.
Health behaviors	<ul style="list-style-type: none"> Individuals living in rural areas often have limited access to resources that lead to positive health outcomes. Additionally, these individuals tend not to exhibit other health behaviors such as physical activity, maintaining a healthy body weight, and getting sufficient sleep. Stress and other environmental factors may lead individuals living in rural areas to adopt unhealthy behaviors such as smoking, drug use, or alcohol use.

TABLE 9.3 Factors Affecting Health Outcomes in Rural Populations (See Rural Health Information Hub, 2023.)

UNFOLDING CASE STUDY

Part B: Addressing Disparities

Read the scenario, and then answer the questions that follow based on all the case information provided in the chapter thus far. This case study is a follow-up to Case Study Part A.

Marinelle contacts the clients who have missed the most prenatal appointments. These clients report difficulty finding transportation to the appointments. Many clients feel stressed about not having enough money and resources to support their families after their infants are born. One client describes her difficulty trying to find a home closer to town and in better condition than her current home. Marinelle works to find reliable transportation for the clients to help them make it to their appointments. She also arranges for a social worker to visit the clients to discuss their economic concerns.

3. What should Marinelle consider as a factor influencing clients living in this neighborhood?
 - a. Racial discrimination
 - b. Residential segregation
 - c. Environmental injustice
 - d. Gender differences

4. Which of the following is the best indicator for Marinelle to use to evaluate the effectiveness of her interventions to address maternal health disparities in this population?
 - a. Client satisfaction
 - b. Provider satisfaction
 - c. Rate of pregnancy-related complications

- d. Number of missed appointments

ACCESS TO MATERNAL HEALTH CARE IN RURAL COMMUNITIES: A PATIENT'S PERSONAL STORY

[Access multimedia content \(<https://openstax.org/books/population-health/pages/9-4-geographical-disparities>\)](https://openstax.org/books/population-health/pages/9-4-geographical-disparities)

In this video, a family discusses the barriers to maternal health services they face while living in a rural area.

Watch the video, and then respond to the following questions.

1. What are some of the specific barriers faced by the family presented in the video?
2. What is the importance of having access to health care services in rural areas?
3. What lessons learned from this situation can be applied to other rural health situations?

Chapter Summary

9.1 Health Disparities Defined

Health disparities occur when there is a difference in health care access and outcomes between two or more groups of individuals. Health disparities occur for various reasons, including limited access to health services due to higher rates of poverty, which limits the ability to purchase health insurance. The key to addressing health disparities is to minimize the effects of the social determinants of health.

9.2 Race and Ethnicity Disparities

Minority health refers to the characteristics and attributes of health specific to a racial or ethnic minority group who are socially disadvantaged and are underserved in health care. Factors that exacerbate inequalities among various groups of individuals include income inequality, environment, racism, sexism, ableism, classism, and homophobia. Systemic and structural racism also disadvantages minority populations. The COVID-19 pandemic exacerbated racial disparities.

9.3 Gender Disparities

Sex refers to the physiological and biological

Key Terms

gender male and female characteristics that are socially constructed

gender identity a person's internal experience and belief of gender, which may or may not correspond to their physiology or designated sex at birth

geographical disparities differences in health care access and outcomes based on where an individual lives

geography a science that deals with the description, distribution, and interaction of the diverse physical, biological, and cultural features of the earth's surface

health care disparities differences among groups related to access and use of health care

health disparities health differences linked to social, economic, and/or environmental disadvantages

health equity the state in which everyone has a fair and just opportunity to attain their highest level of

characteristics of males and females; gender refers to male and female characteristics that are socially constructed. Gender norms are social and cultural principles that influence ideas on how different genders should behave in society. Gender affects people's experiences with and access to health care. Research shows that the LGBTQIA+ population experiences poorer health outcomes compared to the cis-heterosexual population.

9.4 Geographical Disparities

Geography has historically influenced the health and well-being of communities, health care delivery, and health outcomes of the population. Geographical disparities are differences in health care access and outcomes based upon where an individual lives. Disparities exist between rural and urban areas, populations of different states, and even by zip code in the same county. Individuals living in rural areas face issues such as geographic isolation, lower socioeconomic status, higher rates of health risk behaviors, limited access to health care specialists and subspecialists, and limited job opportunities.

health

intersectionality intersecting disadvantages related to the inequities, injustices, oppressions, and privileges perpetuated by structures including racism, classism, colonialism, sexism, heterosexism, ableism, and others

minority health distinctive health characteristics and attributes of racial or ethnic minority populations who are socially disadvantaged due in part to being subject to racist or discriminatory acts and are underserved in health care

sex the physiological and biological characteristics of males and females

socially disadvantaged those who have experienced prejudice or bias because of their identities as members of racial, ethnic, or cultural groups, without regard for their individual qualities and stemming from circumstances beyond their control

Review Questions

1. A public health nurse is reviewing data that shows that families living closer to an industrial plant have higher rates of cancer. Which of the following determinants should the nurse consider in this situation?
 - a. Epigenetics
 - b. Sociocultural environment

- c. Biological processes
 - d. Physical environment
2. A nurse researcher has found that clients living in rural areas tend to have higher rates of hospitalization for chronic lung disease than those living in affluent urban areas. Which of the following terms describes what the nurse researcher has identified?
- a. Health disparities
 - b. Health determinants
 - c. Intersectionality
 - d. Socially disadvantaged populations
3. A community health nurse educates a group of families on healthy eating habits to reduce their risk of diabetes. The nurse encourages them to share healthy meal ideas with each other. Which domain and level of influence does this intervention address?
- a. Behavioral and community
 - b. Behavioral and individual
 - c. Sociocultural environment and interpersonal
 - d. Sociocultural environment and societal
4. A community health nurse is working with a group of gay Black clients who are describing some of the negative social interactions they have experienced. This group is likely affected by which of the following:
- a. Intersectionality
 - b. Entitlements
 - c. Gender disparities
 - d. Racial disparities
5. A home health nurse notices that, among clients who were recently released from the hospital, female clients were more likely than male clients to report experiencing uncontrolled pain while hospitalized. What contributing factor should the nurse consider in this situation?
- a. Gender roles
 - b. Gender biases
 - c. Biological differences
 - d. Environmental differences
6. A public health nurse determines that a non-English-speaking Hispanic client needs additional medical evaluation and treatment for cancer. Which of the following statements best describes the nurse's assessment of this situation?
- a. This client is insured and should be able to receive treatment accompanied by a medical interpreter.
 - b. This client has a primary care provider who should be able to help the client navigate the system.
 - c. This client's access to health care may be limited by the ability of the health care system to provide services when they are needed.
 - d. This client's access to health care may be limited by the availability of culturally competent providers.
7. Which of the following statements by a nursing student would indicate the need for further education?
- a. "A difference in health status between older adults and the young may indicate a health disparity."
 - b. "Race is not a determinant of health."
 - c. "Individuals who live in high-poverty areas may need assistance accessing health care services."
 - d. "If I don't have a high school diploma, my risk for chronic disease rises."
8. A nurse studying the percentage of the population that reports having a regular source of health care notices that some states have significantly higher rates of care than other states. Which of the following factors is most likely the reason for the difference?
- a. Differences in health literacy rates

- b. The geographic distribution of health care providers
 - c. The income requirements for Medicaid eligibility
 - d. Availability of public transportation
- 9.** A nurse educating a group of men on the importance of performing testicular self-exams recognizes that which of the following factors influences the likelihood that they will adhere to this recommendation?
- a. Low health literacy levels
 - b. Poor social support
 - c. Gender bias related to health care access
 - d. Gender norms related to masculinity
- 10.** A nurse working in a rural public health clinic recognizes that which of the following risk factors for poor health outcomes is prevalent in the community?
- a. An increased likelihood of engaging in risky behaviors
 - b. A decreased risk of experiencing chronic lung disease
 - c. An increased likelihood of wearing seat belts
 - d. A decreased risk of cancer

CHAPTER 10

Socio-Ecological Perspectives and Health

FIGURE 10.1 Each person's health is affected by a wide array of factors in their personal and professional lives and in the environments in which they live, work, and play. These workers planting a tree may get good exercise on the job, sometimes they may work in fresh air and sunshine, and they may be able to work and socialize with others on the job, all of which can benefit their health. On the other hand, they may have to work in inclement weather, their work may be physically arduous or even dangerous, they may work by busy roads or highways where they are exposed to loud noise and air pollution, and they may be exposed to other damaging chemicals—for example in fertilizers—all of which can be [detrimental to their health \(<https://openstax.org/r/osha>\)](https://openstax.org/r/osha). (credit: modification of work "Landscaping Crew" by Lisa Chen/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 10.1 Factors That Influence Health Practices
- 10.2 Theories and Models of Health Behavior
- 10.3 Core Principles of the Socio-Ecological Model

INTRODUCTION Mo is a 55-year-old client who is generally in good health. He works full-time for a landscaping company where he maintains lawns and gardens most of the year and shovels and plows in the winter. Recently, Mo has started thinking about how he can stay healthy as he looks toward retirement over the next decade.

The health of clients like Mo is affected by many factors, not solely by their medications, how often they see health care providers, their physical endurance, their family's health, their health insurance coverage, their level of education, or any other single factor. Nurses use theoretical perspectives to perform comprehensive assessments and to plan effective care in partnership with clients. **Theories** provide a means to explain phenomena systematically and to guide thoughts and decision-making processes by fostering an understanding of the causal pathways between factors of health and disease (Eriksson et al., 2018). This chapter describes the many influences on health, socio-ecological models (SEMs), and other theories of health and human behavior. Mo appears throughout the chapter as an example of how an individual's health may be affected by a wide array of circumstances in their personal and professional lives.

10.1 Factors That Influence Health Practices

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 10.1.1 Identify factors that influence individual health practices.
- 10.1.2 Describe how the interaction of genetics, behavior, environmental and physical influences, medical care, and social determinants of health interact to determine a person's health and well-being.

Dynamic and complex interactions among a person, their community, the environment, and society at large influence the overall health experience of clients and communities. Clients' health depends on more than just their own decisions and personal health practices, or health behaviors. **Health behavior** encompasses the actions, habits, activities, policies, and procedures of individual clients, communities, organizations, and governments that can either support or undermine health. The term "behavior" can carry a judgmental or negative connotation that implies blame or moralizes health choices, when in reality the health behavior depends on numerous factors.

For example, whether or not a client participates in physical activity outside of their working time may appear to be their *choice*, and whether or not a client consumes microwaved meals and packaged snacks at each meal rather than eating a lot of fresh fruits and vegetables may be viewed as a *preference*. However, there may be some actions a client would like to take to support their health, but barriers to participation in their home, workplace, community, health system, or greater society may prevent them from doing so. Significant factors impact choices, compulsions, preferences, necessities, and other decision-making processes about health and related activities.

Socio-ecological models (SEMs) are models that offer a way to study and organize how personal, situational, community, societal, political, and other contexts affect client and community health behaviors and outcomes. Socio-ecological perspectives are a focus of this chapter. Before discussing SEMs in more detail, this section explores some of the concepts that can shape, and be shaped by, health behavior.

THE ROOTS OF HEALTH INEQUITIES

Labeling Client "Behavior"

Many factors influence client "compliance" or "adherence" to care plans, suggested health interventions, or engagement with what is generally accepted as a healthy lifestyle. Assigning feeling, meaning, or blame to client health behavior without a thorough consideration of other socio-ecological factors can do serious harm. For example, clients may be labeled "noncompliant" when documenting or discussing a medication plan instead of naming factors such as pharmacy access, financial situations, or unpleasant side effects. This labeling of clients can influence how other providers interact with the client, creating an inequity in providing health care.

(See Cox & Fritz, 2022.)

CASE REFLECTION

Factors That Influence Health Practices

Read the scenario, and then respond to the questions that follow.

While generally healthy, Mo has been diagnosed with dyslipidemia for which he takes atorvastatin; he also has seasonal allergies that he manages well with daily over-the-counter loratadine and fluticasone under the direction of his primary care nurse practitioner. Mo wears corrective lenses. He has the occasional tennis elbow flare-up during his busy seasons at work. About once or twice per year, he experiences respiratory bronchitis and uses an albuterol inhaler as needed. The bronchitis can be particularly bothersome, which motivates him to get his seasonal immunizations like flu and COVID-19 as soon as his local pharmacy has them in stock. Sometimes, he says it is tough to sleep because he lives near the highway, which can be noisy overnight. He has not had any prior surgeries. His family history is significant for dyslipidemia and coronary artery disease; his mother (living) and his father (deceased over 20 years) had type 2 diabetes mellitus and chronic lymphocytic leukemia. Mo has never had genetic testing but is of Ashkenazi Jewish descent. Aside from seasonal allergies, he has no known allergies, and his

immunizations are up to date.

Mo states he does not mind the physical nature of his landscaping work, but each year it seems a bit harder to work quickly. He proudly tells you he also works on his own yard, having planted 100 tulip bulbs for the coming season. He lives with his wife in a single-family home in a small town about 30 minutes by car from the capital city. He uses the 5-mile bicycle and walking path once a week in nice weather. Mo's town has several grocery stores and a large farm where he is able to buy organic produce. Mo has two adult children who do not live at home and one grandchild. His daughter is a nurse, and his son works in finance. Mo spends as much time as possible with his family and socializes with friends a few times per month.

1. Identify three components of Mo's profile that are health-promoting, are risk-reducing, or may affect his health in a positive way.
 2. Identify three components of Mo's health that present health risks, present safety concerns, or may affect his health in a negative way.
-

The Centers for Disease Control and Prevention (CDC, 2019) recognize five main factors that influence health:

- Genetics
- Behavior
- Environmental and physical influences
- Medical care
- Social factors

These factors are discussed below. While reading about these factors, think about how each component identified as either supportive or potentially detrimental to Mo's health could be categorized. The cultural beliefs, norms, values, and practices of clients and families can influence individual definitions, understanding, and experiences of health. For more information on culture and health, see [Cultural Influences on Health Beliefs and Practices](#).

Genetics

Family health history helps identify strong risk factors or predictors for acquiring certain conditions and disorders and alternatively for lowering the risk of health conditions. **Genetics** involves the study of how genes, traits, and diseases are passed from one generation to the next. Although genetic associations can be robust, genetics are still only one component in an overall health picture. As heritability and the presence of certain genes or attributes are measurable, scientists can calculate the impact of genetics versus lifestyle, social, and other factors on specific health risks. Some health conditions can have exceptionally strong genetic linkages, with a high likelihood that if one or both biological parents have a condition, their offspring will have it, too. For example, while the risk of developing breast cancer in the general population is 12.9 percent, children of parents with a certain gene mutation have a 50 percent risk of inheriting the mutation, dramatically increasing the risk of developing cancer (National Cancer Institute, 2020). Some aspects of health may be loosely related to genetics. The heritability of lifespan is only estimated to be between 7 and 25 percent (van den Berg et al., 2019), which suggests that there are many other factors that contribute to how long a client may live beyond the age of their oldest relatives at death.

Mo has a few possible genetic health risks. His parents were noted to have dyslipidemia and coronary artery disease as well as type 2 diabetes mellitus and cancer. Mo may be at increased risk of these conditions from a genetics standpoint, but he may also have had exposure to environmental and lifestyle factors similar to his parents that can precipitate these conditions. Mo is also of Ashkenazi Jewish descent. Ashkenazi Jews are one of several ethnic groups known to carry an increased likelihood of select genetic conditions (National Gaucher Foundation, 2023).

Behavior

Broadly, **behavior** encompasses the way a person acts, the mannerisms they display, and the conduct they employ. *Health behavior* refers to specific actions that support or undermine health. Some individual health behaviors, such as staying adequately hydrated and participating in mindfulness practices like meditation, journaling, or guided imagery, can lower the risk of conditions or lead to improved health. Other health behaviors can precipitate or worsen conditions, such as smoking and getting insufficient sleep. Behavior is one of many factors that can influence client health, and all clients do not have the same access to engaging in select health-promoting

behaviors.

Many recognized structures, inequities, and ideologies, as well as broad societal organization, have a greater influence on health behavior than individual choices and nonconscious processes (Rejeski & Fanning, 2019; Short & Mollborn, 2015). These external factors can create barriers or opportunities that influence the ease with which individuals can engage in health-promoting behaviors. Think back to the examples at the start of this section: a client who does not engage in physical activity and a client who does not eat fruits and vegetables. The client who does not participate in leisure-time physical activity may not have safe places to walk in their neighborhood or might work odd hours that leave little daylight time for walking and jogging. The client who eats mostly packaged foods may not live near a grocery store that sells any fresh fruits and vegetables or sells them at affordable prices. These situations highlight the significance of city planning, equitable access to jobs with daytime hours, and community buying power that could incentivize a full-service grocery store chain to locate a store in the neighborhood. These factors outweigh the influence of clients' personal activity and meal preferences or conscious health decisions. A comingling of other health factors affect whether individuals are aware that a particular factor supports or hinders health.

Mo engages in some health-supporting behaviors, such as keeping up social contacts and participating in physical activity. He also regularly takes medication in support of his identified health conditions and has agreed to receive immunizations as scheduled. Some of his behaviors represent health risks and require further assessment. For example, the physical nature of his job has been a challenge and at times exacerbates his tennis elbow.

Environmental and Physical Influences

When thinking of health and the environment, one may consider several aspects such as access to drinking water and exposure to air pollution. While clean air and water are essential to physical and mental well-being, other aspects of the environment can dictate health status ([Figure 10.2](#)). The primary environment for most people is their home. Even dwellings that clients note as pleasant, comfortable, and preferred can represent health risks. For example, clients who live in multiunit buildings (e.g., apartments or condominiums) and do not smoke still face a health risk if other people in their building smoke in their own home units, on balconies, or outside of the buildings in designated smoking areas that are in close proximity to the living area (Willand & Nethercote, 2020). If the physical environment around a client's home or place of work has a well-marked, smooth, tree-lined sidewalk, this can support engagement in outdoor physical activity. Similarly, living near nature or being able to see green space from a window in the home supports self-esteem, life satisfaction, and happiness and helps clients avoid depression, anxiety, and feelings of loneliness (Soga et al., 2021). Alternatively, living near a highway places a client at risk for hearing constant noise and being exposed to pollution and has been associated with neurodegenerative disorders such as Alzheimer's disease, multiple sclerosis, and Parkinson's disease (Yuchi et al., 2020). A healthy home environment may not be available in densely populated areas. For many people, opportunities to relocate from an unhealthy home environment to an improved setting may not be affordable.

FIGURE 10.2 One of the big reasons for indoor smoking bans is to protect workers from secondhand smoke, an environmental contaminant. While everyone may experience serious health consequences following exposure to secondhand smoke, not everyone faces the same risk. Children, adolescents, and individuals who are non-Hispanic Black, have lower incomes, have less education, live in rental or multiunit buildings, live with a smoker, and work in certain industries face a [disproportionate risk of secondhand smoke exposure](https://openstax.org/r/cdcgovab) (<https://openstax.org/r/cdcgovab>). (credit: "Smoke-free area" by Vasile Cotovanu/Flickr, CC BY 2.0)

THE ROOTS OF HEALTH INEQUITIES

Home Air Quality: Environmental Racism

"Redlining" was a discriminatory home loan practice that emerged in the United States in the 1930s when banks would deny mortgages or offer loans on unfavorable terms to clients and families based on their race. Redlining led to neighborhood segregation and ongoing disparities. Modern-day disparities in air quality can be linked to these nearly 100-year-old practices. Researchers studied the association between air pollution and redlining in 202 cities across the United States. They determined that BIPOC communities, particularly Black and Hispanic people, are exposed to higher levels of air pollution despite general improvements in air quality across the nation. One reason for poor air quality in these communities is the presence of hazardous industrial factories in redlined neighborhoods. While banks and lenders today may have antidiscrimination practices in place and there is legislation meant to prevent redlining, the health impact of this racist practice persists. Higher levels of contaminants such as nitrogen dioxide and fine particulate matter present in formerly redlined neighborhoods can contribute to premature death, chronic conditions across body systems, environmental allergies, cognitive problems in children, and complications with reproductive and fertility health. See [Structural Racism and Systemic Inequities](#) for more information on redlining and [Environmental Health](#) for more information on the negative effects of pollution on health.

(See Lane et al., 2022; Manosalidis et al., 2020.)

The physical environment to which a client has access can impact health and behavior. Consider Mo: Mo exercises regularly in nice weather. He lives in a town that has a 5-mile biking and walking path that he uses for walking and jogging. This walking path gives Mo a safe place to participate in physical activity. If Mo lived in a city that did not have such a path, would he be able to walk for 5 miles on the sidewalk? Would he need to dodge oncoming traffic while jogging? If there was not a path designed specifically for walkers and joggers, would he consider outdoor physical activity too much of a hassle? Without a place to exercise outside, would he need to join a gym? Could he afford to join a gym? Mo is in an ideal position where he enjoys exercise and has access to resources that allow him to exercise in the community environment. On the other hand, living next to a highway may pose a threat to Mo's health due to poor air quality, conditions that are not conducive to sleep, and risk for neurodegenerative disorders.

Medical Care

Medical care refers to services rendered by a health care clinician during visits to clinics, offices, hospitals, surgical centers, schools, labs, and other places. Access to medical care can improve health through prevention, diagnosis, treatment, or palliation of illnesses, injuries, and diseases. The presence or absence of barriers to medical care for clients and communities influence their health behavior. Access to medical care provides clients with preventive health screenings, symptom management, and access to treatment and medications to manage chronic conditions. Access to care depends on many factors, such as a client's insurance status and comfort or trust in specific providers or in the health system as a whole (Greene & Ramos, 2021).

Members of marginalized communities face additional barriers to finding a provider who might welcome them and understand their needs. Older adults, LGBTQIA+ clients, and clients with language barriers are a few examples of those who might have physical access to care but do not fully receive the care they need due to factors such as systemic ageism, heterosexism, and stigma in health settings (Al Shamsi et al., 2020; D'cruz & Banerjee, 2020; Gibb et al., 2020). [Caring for Vulnerable Populations and Communities](#) shares more information regarding the care of populations vulnerable to marginalization, discrimination, and exclusion in the health setting. Even factors that change day to day can impact medical care. For example, scheduling and attending a medical appointment involves: finding time to make a phone call, being able to succinctly describe the health concern, finding a convenient day and time to attend an appointment around work and other commitments, ensuring access to and money for transportation to get to the appointment, paying for the copay in the setting of lost wages, and more. Geographic access to a hospital or care provider can also differ for many Americans in rural versus urban environments. For example, although the United States has climbing maternal morbidity and mortality rates, in recent years access to perinatal services in rural communities has decreased, and these communities have a nine percent greater probability of severe maternal morbidity and mortality compared to urban residents (Kozhimannil et al, 2019).

Mo sees his primary care provider annually and as needed. The primary care clinic is situated in Mo's town, and he finds it easily accessible. This makes his quarterly visits for monitoring of chronic conditions easy, and Mo has never missed an appointment for a cholesterol check. Mo can quickly see the primary care provider for an evaluation of his respiratory health and inhaler refills as needed. If he ever needed surgery or inpatient care, he could easily access the larger hospitals in the capital city, which is only about 30 minutes away by car. Further, his daughter is a nurse, which gives him access to extra support. She can help him make sense of any of the primary care provider's recommendations or test results and can help him prepare to explain his health issue in a succinct manner to make the most of any visit scheduled. The same is not true for many Americans. Health inequities are apparent and harmful when clients face barriers such as limited health plan coverage, living far away from hospitals and clinics, language barriers, or lack of family support. Any barrier to care access can impact a client's ability to receive care, which can lead to poor health outcomes and continuation of society-wide health inequities.

A CRISIS IN MATERNAL CARE ACCESS

An increasing number of locations in the United States are becoming "maternity care deserts," leaving pregnant clients and families without access to birth centers or hospitals and providers that can provide obstetric care. In a [2022 report](#) (<https://openstax.org/r/marchofdimessites>), March of Dimes determined that the growth of these deserts was affecting nearly 7 million people of childbearing potential and over a half million babies. March of Dimes developed a [companion site](#) (<https://openstax.org/r/marchofdimes>) to the report with summaries and interactive maps. *Please note, the report refers to women and mothers. Authors and editors of this textbook acknowledge and support that women and mothers are not the only clients with childbearing potential.*

Visit the links, and then respond to the following questions.

1. What are the health consequences of living in a maternity care desert?
2. Is your school or home in an area considered a maternity care desert?
3. How do clients receive medical care when living in a maternity care desert?
4. What individual health behaviors are impacted when living in a maternity care desert?
5. What might it take to eliminate maternity care deserts?

Social Determinants of Health

Social determinants of health (SDOH) have crossover with the factors previously discussed, but they also bring different perspectives and antecedents to a client's full health picture. Other chapters within this textbook discuss SDOH in greater depth. Briefly, per Healthy People 2030, social determinants of health are the conditions and environments where people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks (Office of Disease Prevention and Health Promotion [ODPHP], n.d.-a); they are discussed at length in [Social Determinants Affecting Health Outcomes](#). Social determinants across domains, including a client's economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context can influence or are influenced by the factors associated with health behavior.

Not all clients have the same access to engaging in healthy behaviors and lifestyle interventions. For example, teen clients have identified support from caregivers, family members, and peers regarding healthy eating and exercising and access to organized sports as two factors essential to facilitating a healthy lifestyle (Cardel et al., 2020). What happens to teens without such supports? There are many benefits to outdoor play for children and teens alike (Chaudhury et al., 2019; McCormick, 2017), and nurses might suggest increasing outdoor play time to families during health encounters. Unfortunately, not all clients and families have the same access to recreational areas, parks with amenities such as play structures, vegetation, and outdoor spaces with tree canopy and shade coverage in their neighborhoods (Kephart, 2022). How might a nurse approach suggesting increased outdoor activity for families that are not afforded access to safe green space ([Figure 10.3](#))? While nurses can acknowledge that health behaviors can bolster or hinder personal health and wellness, they must remember that placing ultimate accountability for engaging in health behaviors solely on an individual is not in alignment with nursing practice principles of justice and equity.

FIGURE 10.3 A preschool-aged child plays tag indoors. When communities do not have access to robust green space, nurses can counsel families on creative indoor physical activities. Nurses can recommend activities that encourage movement, fun, and family bonding, such as online guided dance or exercise classes on sites like YouTube or different indoor games for children of all ages. (credit: "Playing Tag with Milly" by Donnie Ray Jones/Flickr, CC BY 2.0)

Mo's social determinants affect his experience of health. He considers himself economically stable. He finished high school, he is employed full-time, and he owns a home. He has health plan coverage and, as discussed, can easily access health services when he needs them. He enjoys the environment in his own backyard and can access outdoor recreation space in his neighborhood. Mo has a positive social and community context. His job does pose health risks to both his musculoskeletal function (tennis elbow) and respiratory wellness (allergies and bronchitis). He knows that living near the highway can affect his sleep, and he might be surprised to hear about the risks that

traffic and pollutants pose to his respiratory conditions—and to the vibrancy of his tulip garden! All in all, Mo's social determinants contribute to a positive experience of health.

Intersectionality

None of the factors that influence health behavior exist, form, evolve, or influence on their own. Similarly, barriers or health risks relevant in one factor or category can worsen those in another and perpetuate inequalities and injustices in health. **Intersectionality** considers how more than one disadvantage can interact for clients on an individual level and reflect the inequities and injustices at the systems level. Racism, classism, colonialism, sexism, heterosexism, and ableism are a few of the structures that result in systems-level oppression and privilege (Crenshaw, 1991). Intersectionality focuses on systems of oppression and privilege, not individual identities, and while all people have intersecting social identities, not all people belong to groups that are harmed by oppressive structures or supported by subsequent privilege (Aguayo-Romero, 2021). Considering the intersectionality of genetics, behavior, environment, medical care, social determinants, and societal structures allows for a better understanding of the complexity of health and illness across the population. It also serves as a reminder to all clinicians that addressing disparities, inequities, biases, injustices, and other problems that perpetuate oppression in health care is a priority that must be addressed to promote health for all.

INTERSECTIONALITY

[Access multimedia content \(<https://openstax.org/books/population-health/pages/10-1-factors-that-influence-health-practices>\)](https://openstax.org/books/population-health/pages/10-1-factors-that-influence-health-practices)

This CDC video defines intersectionality and explores its role in health outcomes.

Watch the video, and then respond to the following questions.

1. How would you define intersectionality?
2. What different groups do you belong to?
3. The video states that public health professionals can use the intersectionality framework as an equity lens. What does this mean?

10.2 Theories and Models of Health Behavior

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 10.2.1 Explain the purpose of theories and models of health behavior.
- 10.2.2 Describe five common theories and models nurses may use with clients.

Health behavior can support or undermine client health. Healthy behaviors and lifestyle interventions can prevent illness, ameliorate symptoms, and improve overall health. Some examples of healthy behaviors and lifestyle intervention include changing one's diet, engaging in physical activity, stopping smoking, practicing harm reduction, managing stress, and attending support groups (Wang & Geng, 2019). Nurses often provide client teaching related to healthy behaviors and lifestyle interventions that, in concert with prescriptions and medical treatments, can support client well-being. Models and theories of health behavior can guide nurses in identifying health behaviors requiring change in clients and communities and methods for accomplishing health promotion and disease prevention through behavior change. As client, family, and community behaviors that promote health and reduce risk are essential to meeting population health goals, this section will discuss models and theories relevant to the study and change of health behavior. A wide range of clinicians have used Social Cognitive Theory, Theory of Planned Behavior, Health Belief Model, Transtheoretical Model/Stages of Change, and Pender's Theory of Health Promotion in various contexts to describe client health behavior and promote engagement in healthy behaviors, such as diet, mobility, and other aspects of care and treatment.

HARM REDUCTION PRACTICES

Harm reduction refers to practices in health care that support clients who engage in known risk behaviors with

kindness, compassion, and respect. Many harm reduction experts report that harm reduction is “meeting people where they are,” meaning clinicians can recognize that select behaviors carry risk but that for personal want or need the client is not planning to stop the behavior. Harm reduction strategies may include educating clients who are sex workers on the use of barrier methods and birth control or providing clients who use injection drugs with clean syringes and test kits to confirm the contents of injected drugs. Harm reduction is a departure from past ineffective practices of advising clients to simply stop participating in risky behaviors.

Visit the [National Harm Reduction Coalition \(<https://openstax.org/r/diseasecontrol>\)](https://openstax.org/r/diseasecontrol) website for information and resources on key issues such as syringe access, overdose prevention, sex work, hepatitis C, supervised consumption services, and xylazine.

Click on one of the topics, and then respond to the following questions.

1. How does the information on the website differ from what you may have previously read, heard, or learned about the issue?
2. What information on the website is congruent with what you may have previously read, heard, or learned about the issue?
3. Can you name one action you can take in your future nursing practice to implement harm reduction?
4. How might you use the principles of health behavior change to partner with a client to reduce their risks?

Social Cognitive Theory

Albert Bandura developed the Social Cognitive Theory to analyze and explain human function with consideration of the dynamic interactions among the individual, the environment, and their behavior (Bandura, 2001b). Bandura’s theory assumes that people are active agents in their own development and that they are proactive, self-regulating, self-reflecting, and self-organizing but that their personal agency is influenced by social systems (Bandura, 2001a). Individual factors may include personal values, self-efficacy, and outcome expectations. Environmental factors include the feedback and behaviors of others. The behavioral component may involve prior behavior and experiences. Per the Social Cognitive Theory, an individual’s behaviors ultimately are determined by interactions of personal goals, self-efficacy, outcome expectations, and social factors (Bandura et al., 1999). The theory has become one of the foremost in the area of motivation and is used in health to predict and understand clients’ health behavior (Schunk & DiBenedetto, 2020; Wu et al., 2021). The theory is most applicable to behaviors that are planned, requiring forethought on the part of the client, in contrast to decisions that may be made in the moment (Bandura, 1991).

Improving access to care for clients and families in rural settings can improve population health outcomes. One way to improve care access is to support client engagement as active members of their own care team. Researchers recently conducted a study to determine the impact of interventions based in Social Cognitive Theory on the self-efficacy of older rural clients in participating in their own health care (Ohta et al., 2021). A total of 156 clients aged 65 years and older from three different rural communities participated in educational sessions regarding health management, health literacy, collaboration, shared decision-making, and chronic disease, all with consideration of the personal, environmental, and behavioral factors relevant to the Social Cognitive Theory. Another 121 clients, also aged 65 years and older, did not attend any educational sessions. All clients completed questionnaires regarding participation in health management and collaboration with clinicians and participated in research interviews about engagement and collaboration in their own health care. The researchers determined that rural older adults can be motivated to participate in their own care and collaborate with clinicians. They also identified facilitators and barriers from each aspect of the Social Cognitive Theory. Education and empowerment were clear facilitating factors. Regarding barriers to participating, individual views on the hierarchy between clinicians and clients contribute to low health care self-efficacy. Researchers found that a reluctance of these individuals to speak up or challenge hierarchy contributed to a lack of motivation to meaningfully participate in care. The rural environment was also a barrier compared to an urban environment as rural residents have fewer opportunities for mutual assistance with their health needs and may socialize less often. This finding points to the need for strong community health programming to support care access and population health goals.

Theory of Planned Behavior

In developing the Theory of Planned Behavior, psychologist Icek Ajzen postulated that it is possible to predict an individual's intention to perform a behavior. Intent to behave in a certain way as well as variance in the behaviors of an individual are accurately predicted through analysis of attitudes toward the behavior, subjective norms, and perceived behavioral control (Ajzen, 1991). Per the theory, individuals' perception that a behavior will have an expected outcome, perception of the risks and benefits of the outcome, and attitude contribute to their intent to behave in a certain way. The following are concepts important to this theory:

- Intention: willingness or desire to perform an action
- Attitude: feelings about an action
- Subjective norms: thoughts of the greater society on the action
- Perceived behavioral control: belief in the ability to or access to carrying out an action
- Risk perception: thoughts about benefits and hazards of acting or not act

For example, if Mo perceives that wearing protective headphones while working with landscaping equipment will preserve his hearing and that the headphones are not too uncomfortable, and he cares about preserving his hearing, he is likely to wear protective headphones at work. Alternatively, if he does not think protective headphones impact his hearing or that working around loud equipment can damage hearing, and if he thinks that the headphones are uncomfortable, he is unlikely to change his behavior. The intent, or motivation, coupled with a person's actual ability to perform the behavior predict behavioral achievement. Ajzen designed the theory to help explain all behaviors that can be self-controlled. Researchers have used this theory to understand human behavior related to farming practices, consumer habits, and tourism behaviors, and this theory has been used to understand wildlife behavior as well (Choi & Johnson, 2019; Miller, 2017; Savari & Gharechae, 2020; Ulker-Demirel & Ciftci, 2020).

Psychology researchers have used the Theory of Planned Behavior to examine the perceptions and experiences of 114 winter sports participants about sun-safe behaviors and related perceptions (Knobel et al., 2023). Although many people associate sunscreen use with outdoor summer activities, the risk of sunburn and skin cancer is present throughout all seasons ([Figure 10.4](#)). Study participants answered questions about how often they used sunscreen, their intent to use sunscreen the next time they engaged in a winter outdoor sport, how they feel when using sunscreen, norms about sunscreen use, and perceived risks of using or not using sunscreen. Concepts of the Theory of Planned Behavior were strongly associated with sun-safe behaviors. For example, winter sports participants who intended to use sunscreen the next time they participated in winter sports were most likely to engage in sun-safe behaviors. Another example of a key factor in explaining the variation in using or not using sunscreen was the perceived behavioral control, meaning the participants who found sunscreen application easy to do and accessible were more likely to practice sun safety. Using the theory to organize the survey and results, the researchers were able to suggest ways to develop guidelines for promoting sun safety among winter sports participants.

FIGURE 10.4 As noted in the Healthy People 2030 box below, skin cancer is the most commonly diagnosed cancer in the United States, and it is preventable. Nurses can lead or become involved in public and private campaigns to educate individuals on the dangers of prolonged unprotected sun exposure and on the effective use of sunscreens every day, not just at the beach or in the summer. (credit: "Sunbather" by Eden, Janine and Jim/Flickr, CC BY 2.0)

HEALTHY PEOPLE 2030

Reduce the Proportion of Students in Grades 9 through 12 Who Report Sunburn

The most commonly diagnosed cancer in the United States is skin cancer, most of which is preventable. One method for preventing skin cancer is through regular use of sunscreen. Over 50 percent of high-school-aged students report having a sunburn annually. One goal of Healthy People 2030 is to [decrease the proportion](https://openstax.org/r/healthgob) (<https://openstax.org/r/healthgob>) of high-school-aged students that experience sunburn through implementing health promotion and educational activities about sun and skin safety.

(See ODPHP, n.d.-d.)

Health Belief Model

In the 1950s, the U.S. Public Health Service struggled to educate the public on the importance of preventing disease and engaging in screening tests to detect asymptomatic conditions, even when preventative interventions and screenings were provided at no cost (Rosenstock, 1974). The Service and behavioral researchers set out to develop a model that could describe behaviors related to the avoidance of disease. The resulting Health Belief Model (HBM) suggests that an individual's belief of how threatening an illness or disease may be, coupled with the belief in the effectiveness of a recommended behavior, predicts the likelihood of engaging in a health behavior. Many researchers and health program leaders have used this model to explain and predict acceptance of health and medical care recommendations (Janz & Becker, 1984). Through research and application of the original model, its modern interpretation includes key constructs of perceived susceptibility, perceived severity, perceived benefits, perceived barriers, cues to action (e.g., readiness), and self-efficacy (Skinner et al., 2015). Susceptibility and severity work together to compose an individual's perceived threat. For example, an individual may be susceptible to a common cold if they spend time with a friend who has a cold but do not consider the cold a severe illness and therefore see little health threat in socializing with an ill contact.

A group of nurse researchers studied college students' behaviors related to vaccination for preventing the human papillomavirus (HPV), using the Health Belief Model to guide their work and findings (Oh et al., 2021). HPV is the most common sexually transmitted infection in the United States and is associated with cervical cancer, genital

warts, and other cancers. Vaccination can prevent transmission of the virus as well as its progression. After surveying 306 students about their health care access, sexual activities, HPV knowledge and threat assessment, and intent to take action via vaccination, the nurse researchers were able to define barriers and facilitators of vaccine uptake based on the Health Belief Model. These findings also enabled them to determine those students most at risk of not receiving the vaccine. For example, students who self-identified as Black and did not speak English at home were less likely than other students to complete the HPV vaccine series. Knowing which students were most at risk for not completing the vaccine series allowed appropriate targeting of health promotion activities. In alignment with the Health Belief Model, the researchers also identified increasing knowledge about HPV, promoting the benefits of HPV vaccination, and health care provider recommendations to become vaccinated as factors that would support engagement in healthy behaviors among college students.

HEALTHY PEOPLE 2030

Reduce Infections of HPV Types Prevented by the Vaccine in Young Adults

A widely available vaccine can help prevent many cases of cancers caused by HPV infection. All children should be encouraged to start the HPV vaccination series at age 11–12 years. There is a critical need for nurses and other care providers to [promote this vaccine series \(\)](https://openstax.org/r/healthypeopleb) and to provide education on the risks and prevalence of HPV.

(See ODPHP, n.d.-c.)

The Transtheoretical Model/Stages of Change

Researcher James Prochaska and colleagues identified six specific stages of behavior change following studies of smokers (DiClemente & Prochaska, 1982; Prochaska & Velicer, 1997). These stages, along with 10 processes of change, form The Transtheoretical Model, also known as the Stages of Change. Since its original development, the model has been applied to behavior change related to substance use, mental health, disease prevention, cancer screening, sun exposure, and pregnancy prevention (Skinner et al., 2015). The model posits that individuals progress through precontemplation, contemplation, preparation, action, maintenance, and termination when changing a behavior. Individuals in

- *precontemplation* do not intend to take action in the next 6 months,
- *contemplation* intend to take action within the next 6 months,
- *preparation* intend to take action in the next 30 days and have taken behavioral steps toward change,
- *action* change overt behavior for less than 6 months,
- *maintenance* change overt behavior for more than 6 months, and
- *termination* have no temptation to relapse and full confidence in maintaining the change (Skinner et al., 2015).

This model allows for consideration that behavior change occurs over time and does not always happen in a linear fashion. Meaning, the thoughts and actions of clients may move “backward” through the stages as they progress to a long-term behavior change. As an example, the client who has quit smoking cigarettes for 7 months may pick up smoking again for 1 month and decide to start the cessation process once more. This client would move from maintenance to contemplation or preparation as they work toward eliminating a health risk behavior once more.

Nurse researchers developed a walking program to improve metabolic control in clients with type 2 diabetes mellitus (Kaplan Serin & Citlik Saritas, 2021). Using the Stages of Change, researchers coached a cohort of clients through walking training five times, four times, three times, two times, and one time during the precontemplation, contemplation, preparation, action, and maintenance stages, respectively, over the course of 10 weeks. They also shared concepts such as the benefits of walking, the consequences of a sedentary lifestyle, and tips for walking comfortably and enjoying exercises via 30–45-minute coaching calls. The intervention group also received daily text messages or brief calls reminding them to exercise and/or record clinical parameters such as blood glucose or blood pressure. Another cohort of clients received no training regarding the walking program but did receive twice-weekly calls reminding them to exercise. Seventy-five percent of clients in the intervention group and 17 percent of clients in the control group progressed through the Stages of Change. At the end of the study, members of the intervention group had improvements in daily average step counts, body mass index, metabolic output, and blood pressure

readings. The nurse researchers concluded that walking for behavior change supported by the Transtheoretical Model can improve metabolic control for clients with type 2 diabetes mellitus.

Health Promotion Model

Nurse theorist Dr. Nola Pender developed the Health Promotion Model over 40 years ago (Pender, 2011). The model aims to help nurses understand the determinants of health behavior to promote health through effective behavioral counseling. The major concept of the Social Cognitive Theory—that individual factors, behavior, and environment interact—is foundational to the Health Promotion Model (Srof and Velsor-Friedrich, 2006). While Social Cognitive Theory and other theories and models of health behavior might address some of the same concepts in client, family, and community care, Pender developed the Health Promotion Model with a focus on nursing. The model directs nurses to assess for eight beliefs when planning for behavior change and health intervention. [Table 10.1](#) lists the eight beliefs. Dr. Pender developed a brief manual for the Health Promotion Model, [linked here](#) (<https://openstax.org/r/deepblue>), which includes a sample clinical assessment to guide nurses as they work with clients on health promotion and behavior change.

Belief	Description
Perceived benefits of action	Perceptions of the positive or reinforcing consequences of undertaking a health behavior
Perceived barriers to action	Perceptions of the blocks, hurdles, and personal costs of a health behavior
Perceived self-efficacy	Judgment of personal capability to organize and execute a particular health behavior; self-confidence in performing the health behavior successfully
Activity-related affect	Subjective states or emotions occurring before, during, and following a specific health behavior
Interpersonal influences (family, peers, providers)	Norms, social support role models—perceptions concerning the behaviors, beliefs, or attitudes of relevant others in regard to engaging in a specific health behavior
Situational influences (options, demand characteristics, aesthetics)	Perceptions of the compatibility of life context or the environment with engaging in a specific health behavior
Commitment to a plan of action	Intention to carry out a particular health behavior, including the identification of specific strategies to do so successfully
Immediate competing demands and preferences	Alternative behaviors that intrude into consciousness as possible courses of action just before the intended occurrence of a planned health behavior

TABLE 10.1 Health Promotion Model Beliefs (See Pender, 2011.)

Health promotion behaviors during pregnancy can help pregnant people prevent complications and support positive outcomes for newborns. Complications such as preterm labor and small-for-gestational-age infants are not always avoidable. However, health behaviors, including physical activity, stress management, and consuming nutrient-dense foods, can help pregnant clients avoid such complications and support a healthy pregnancy. Further, promoting health and reducing risk in individual client pregnancies supports broader population health goals related to improving infant mortality and maternal health. The Health Promotion Model guided a recent study aiming to determine predictors of health-promoting behavior in pregnant women (Jalili Bahabadi et al., 2020; please note the study specifically notes pregnant women; however, this chapter's editors and authors acknowledge that other people are capable of pregnancy). Through surveys of 300 pregnant women, researchers identified social support, perceived barriers, and perceived benefits of health-promoting lifestyles as influential on whether or not pregnant women would engage in health-promoting lifestyles. Using concepts from the established model to form the study and organize the results allows for targeted interventions going forward. For example, increasing awareness among pregnant clients of the benefits of health-promoting behaviors is one way to inspire the adoption of healthy activities.

HEALTHY PEOPLE 2030

Reduce the Rate of Infant Deaths

Changes in access to health care for pregnant people and continuation of health coverage per state policy for birthing parents and babies is one systems-level intervention that has contributed to a decreasing infant death rate over the last decade. Still, thousands of infants die from conditions such as preterm birth and low birth weight each year—and there are notable disparities by race/ethnicity, income, and geographic location. Healthy People 2030 aims to [reduce the rate of infant deaths](https://openstax.org/r/healthinfants) (<https://openstax.org/r/healthinfants>) and 3 years into the program has seen rates improve from 5.8 infant deaths before age 1 per 1,000 live births to 5.4 infant deaths before age 1.

(See ODPHP, n.d.-e.)

THEORY IN ACTION

Adopting a Health Behavior

Think back to Mo from the Case Study as you watch one of these short videos on the theories discussed earlier in the chapter. Select one video below to review a theory or model.

- [Social Cognitive Theory](https://openstax.org/r/socialcognitivetheory) (<https://openstax.org/r/socialcognitivetheory>)
- [Theory of Planned Behavior](https://openstax.org/r/plannedbehaviour) (<https://openstax.org/r/plannedbehaviour>)
- [Health Belief and Transtheoretical Models](https://openstax.org/r/healthbeliefa) (<https://openstax.org/r/healthbeliefa>)
- [Pender's Health Promotion Theory](https://openstax.org/r/healthpromotionmodel) (<https://openstax.org/r/healthpromotionmodel>)

Watch the video, and then complete the following exercise.

1. Pick one of Mo's health problems or a condition he may be at risk for (the health problem may be acute, chronic, self-limiting, or requiring treatment and may be individual or a risk for his family/community).
2. Identify a health-promoting behavior that can address Mo's actual or potential health problem.
3. Use your selected theory or model of health behavior described in the video to predict barriers, facilitators, and/or nursing interventions related to the chosen health-promoting behavior.

10.3 Core Principles of the Socio-Ecological Model

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 10.3.1 Identify the core principles of socio-ecological models.
- 10.3.2 Describe how socio-ecological models serve as a framework to understand how behaviors both affect and are affected by various contexts.
- 10.3.3 Discuss health behavior using the components of a theory or model.

The Socio-Ecological Model (SEM) is a classic theory of child development that scholars and clinicians from different disciplines have adapted over time to fit the phenomena of other fields. Its core principles encourage the view of individuals as existing within many relationships and contexts. A consistent idea among similar models is that multiple factors can influence health, and clinicians, educators, researchers, and policymakers must take a broad approach to thinking about health and the many shaping factors. Using the SEM as well as theories facilitating an exploration of the nested, interdependent, intersectional, dynamic interactions of individuals and their surroundings in today's complex world will help nurses meaningfully understand and address health problems. The Socio-Ecological Model offers a way to study and organize how personal, situational, community, societal, political, and other contexts influence health behaviors and outcomes. Nurses and nursing students can guide their professional practices with this model to support thorough assessments of client health and targeted, realistic care planning, among other benefits. While SEMs can help structure the research, work, planning, and implementation processes of nurses in community/public health, remember that SEMs may not include all contextual factors that are important to a particular community or specific health problem. Further, not all findings from work guided by SEMs

will apply to individuals within a population or community.

The current version of the model has evolved from many interprofessional theories and studies of health and behavior that started in the 1970s with psychologist Urie Bronfenbrenner, who called for researchers to consider how human growth and behavior can both accommodate and change based on environments and systems and how people interact with them (Bronfenbrenner, 1977). Bronfenbrenner originally developed this model to describe child development and identified four systems nested around the individual child that impact development: microsystem, mesosystem, exosystem, and macrosystem. Years later, Bronfenbrenner added chronosystems as an additional context imperative to consider in analyzing child development (Bronfenbrenner, 1986). [Table 10.2](#) presents definitions of each system.

System	Definition
Microsystem	Complex relations between the developing individual and environment and the immediate setting of the individual. The setting is a place with particular features in which the individual engages in particular activities in particular roles—for example, their home (a child), school (a student), or workplace (an employee).
Mesosystem	The interrelations among major settings containing the developing individual at a particular point in their life—for example, interactions among family, school, and peer groups.
Exosystem	An extension of the mesosystem that includes other specific informal and formal social structures that do not contain the individual but do encompass the settings where the individual is found—for example, major institutions of society, the neighborhood, mass media, government agencies, and social networks.
Macrosystem	Institutional patterns of the culture and subculture. Macrosystems direct norms and activities. A macrosystem may include codified laws, regulations, and rules but can also include informal and implicit norms. For example, the economic, social, educational, and legal systems shape the meaning and motivation of how individuals are treated and interact with each other in different settings.
Chronosystem	The influence of time on an individual's development, including life transitions and events over the course of life.

TABLE 10.2 Systems of Bronfenbrenner's Socio-Ecological Model (See Bronfenbrenner, 1977; 1986; 1995.)

UNICEF Socio-Ecological Model

Specific to population health, the United Nations Children's Fund (UNICEF) uses a SEM as a conceptual framework for many health-promoting initiatives (Baudot, 2015). The model facilitates an analysis of barriers and benefits to health. For example, researchers have used the model to study and improve health in complex settings related to organization priorities, including childhood immunization in Nigeria, nutrition in the Marshall Islands, suicidal ideation in China, and the relation of poverty, the environment, and menstrual health management in India (Angeli et al., 2022; Kodish et al., 2022; Olaniyan et al., 2021; Zhou et al., 2022). Levels of the UNICEF model include individual, interpersonal, community, organizational/institutional, and policy/systems (also known as enabling environments). UNICEF also specifies methods or actions to take to effect change at each level. [Table 10.3](#) provides definitions of the levels and actions for health change.

Level	Definition	Method for Change
Individual/ Interpersonal	Knowledge, attitudes, and practices among a person (individual) and families, friends, and social networks (interpersonal) that affect decisions and actions	Advocacy Social mobilization
Community	Social beliefs and norms, economic conditions, community resources, knowledge, and attitudes about an issue among community members, and the sense of empowerment and efficacy in a community that impacts choices, decisions, and practices	Behavior change communication and social change communication

TABLE 10.3 UNICEF Socio-Ecological Model Levels and Methods for Change (See Baudot, 2015.)

Level	Definition	Method for Change
Organizational/ Institutional	Conditions of a system (e.g., educational system, health care system) that affect inclusion and quality, such as specific institution policies, guidelines, access, geographical proximity, physical infrastructure, resource management, capacity, and safety	Social mobilization
Policy/System Enabling Environments	Policies and governance that either facilitate or discourage inclusivity and quality	Advocacy

TABLE 10.3 UNICEF Socio-Ecological Model Levels and Methods for Change (See Baudot, 2015.)

CDC Social-Ecological Model

The CDC has also used a social-ecological model (also SEM) for violence prevention to help community health clinicians and other workers in the field of violence prevention better understand the factors that influence violence, place people at risk of violence, and protect people from perpetrating or experiencing violence (CDC, 2022). The CDC model has four levels: individual, relationship, community, and societal. [Table 10.4](#) defines the levels of the model and includes proposed prevention strategies to address violence at each level.

Level	Definition	Prevention
Individual	Factors of an individual's biological or personal history that increase the likelihood of experiencing violence or becoming a perpetrator. For example, age, education, income, substance use, and history of abuse may correlate with violence.	Promote violence-prevention attitudes, beliefs, and behaviors (e.g., healthy relationship skill programs and conflict resolution training).
Relationship	Close relationships, meaning those with social peers, partners, and family members, influence an individual's behavior and can contribute to the violence experience.	Prevention and mentoring programs for parents and families that strengthen parent-child communication and promote healthy relationships.
Community	Schools, workplaces, and neighborhoods in which social relationships occur. Some communities have characteristics that are associated with becoming victims or perpetrators of violence.	Improving the physical and social environment across community settings and addressing other conditions, such as poverty and alcohol access, that support violence in communities.
Societal	Broad societal factors that either encourage or inhibit violence. Social and cultural norms and health, economic, educational, and social policies that maintain inequalities between groups may promote violence.	Promote societal norms that are protective against violence, and bolster household economic security, opportunities for education and employment, and policies that affect structural determinants of health. Figure 10.5 shows an example of change at the societal level.

TABLE 10.4 CDC Social-Ecological Model Levels and Prevention Strategies (See CDC, 2022.)

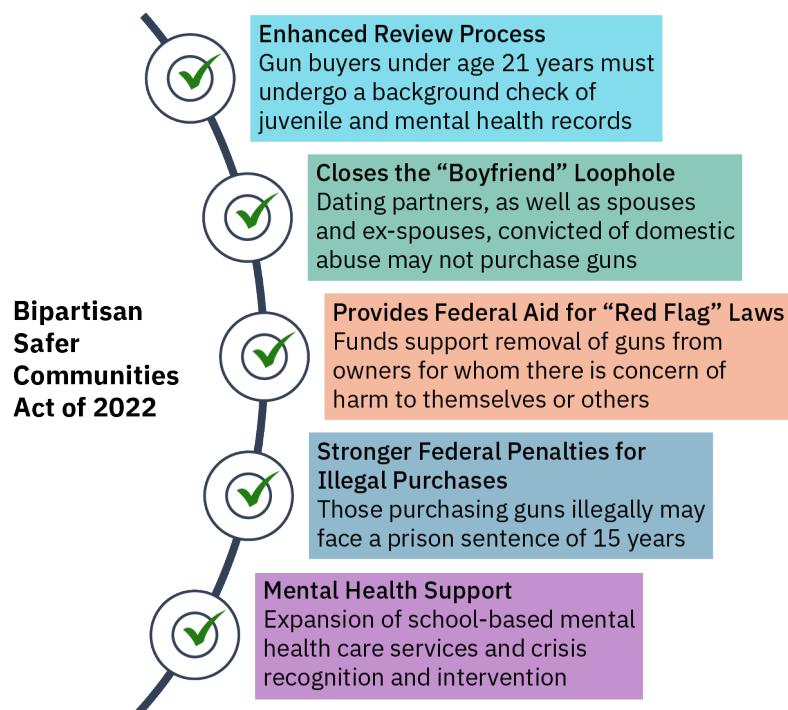

FIGURE 10.5 Access to a weapon can significantly increase the harm caused by violent incidents. Legislative measures included in the 2022 Bipartisan Safer Communities Act can mitigate the occurrence and impact of violence in communities. This bill represents the most significant federal legislation to address gun violence in nearly 30 years. HEALTHY PEOPLE 2030

Reduce Firearm-Related Deaths

Firearm-related injuries and deaths are a major health issue in the United States, and the problem is worsening. In 2018, there were 11.9 firearm-related deaths per 100,000 people in the United States, and by 2021 that number had increased to 14.6. The United States averages almost two mass shootings per day in which four or more people are killed or injured. Deaths and injuries following homicides, suicides, unintentional injuries, and mass shootings are both tragic and preventable with comprehensive policy and community-focused approaches. [Generating such solutions \(<https://openstax.org/r/healthfirearm>\)](https://openstax.org/r/healthfirearm) remains elusive and contentious and must start with acknowledgement of gun violence as a public health problem. For more information on ending gun violence, visit the [Everytown for Gun Safety \(<https://openstax.org/r/everytownresearch>\)](https://openstax.org/r/everytownresearch) site.

(See ODPHP, n.d.-b; O’Rourke, 2023.)

THEORY IN ACTION

The Social-Ecological Model, Health Promotion, and Gun Violence

[Access multimedia content \(<https://openstax.org/books/population-health/pages/10-3-core-principles-of-the-socio-ecological-model>\)](https://openstax.org/books/population-health/pages/10-3-core-principles-of-the-socio-ecological-model)

In this video, Mighty Fine of the American Public Health Association shares information about deaths and injuries secondary to gun violence. He notes that homicides, unintentional shootings, assaults, suicides, and mass shootings are events that contribute to gun violence being a major public health problem in the United States.

Watch the video, and then complete the following exercise.

Categorize each of the interventions that Fine discusses based on the level of prevention and the level of the CDC Social-Ecological Model.

Levels of prevention include:

- primordial,
- primary,
- secondary,
- tertiary, and
- quaternary.

The CDC Social-Ecological Model levels include:

- individual,
- relationship,
- community, and
- societal.

Models in Research and Practice

Using models and frameworks is not just for major organizations. Nurses and care teams can demonstrate, assess, evaluate, and plan for the complex and interacting nature of individual, community, and system factors through the use of models and frameworks. Nurses can impact change across levels by using these models and frameworks and considering the many factors that can impact the development of health problems and the success or failure to adequately address problems. Client behaviors can affect their health, institution, community decisions, and larger system policies. Occurring concurrently, institutions, communities, policies, and social factors affect client health and behavior. Research teams also use these models to direct studies and organize data so meaningful clinical change can result. This section will explore several recent population health projects that were guided by the SEMs.

Health literacy measures how well clients can find, understand, and use information and services to make informed health decisions for themselves or others. When health literacy is poor, clients may not engage in health care services, may lack sufficient access to care, and may not employ health-promoting behaviors. Researchers used the SEM to guide a study of factors at the interpersonal and organizational levels that impact health literacy among clients seeking care at a **federally qualified community health center** (FQHC) (Greaney et al., 2020). FQHCs are clinics providing primary care services to all clients regardless of their ability to pay (Centers for Medicare and Medicaid Services, 2017). Ensuring that the clinicians of FQHCs are prepared to address and improve health literacy is important in helping clients access their care and improve their health. As the SEM posits that individual behaviors are influenced by intrapersonal, interpersonal, organizational, community, and policy-level factors, the researchers determined that exploring the interpersonal and organizational levels via staff interviews was essential to understanding health literacy at these critical centers. Staff participants recognized the impact of health literacy on client and population health outcomes and discussed creating a centralized health information database for clients of varying levels of health literacy. Such a database could include pictures and other visual aids to communicate health information. Training for staff on assessing health literacy among clients was also suggested, representing an organizational-level change that supports interpersonal clinician-client health communication.

Pregnancy in children and adolescents poses significant health risk to both the pregnant person and the infant. Pregnant children and adolescents are at a higher risk of mortality, preterm delivery, and delivering low birth weight babies (World Health Organization [WHO], 2023). In addition to physical health risks, young pregnant people face challenges completing their education and maintaining employment, which have both immediate and long-term implications for the health of the individual and their family. Researchers used the SEM to guide a study of contraceptive service use in the Ebonyi State of Nigeria, given the model's ability to help describe the multiple layers and influences of environmental, social, and community factors that influence health behavior (Ezenwaka et al., 2020). [Table 10.5](#) provides a listing of factors impacting contraceptive access at each SEM level related to this study. The research team determined that many barriers to accessing contraception existed across the SEM levels for youth in the Ebonyi State, and most were not within the control of children or adolescents. Strategic involvement of community partners, clinicians, and community adults would be essential in promoting contraceptive service use among children and adolescents.

SEM Level	Factors
Individual	Poor awareness and knowledge of contraception Fear and experience of side effects Cost of services Lack of confidence/low self-esteem related to seeking contraception
Interpersonal	Poor parental communication of sexual health matters
Community (cultural, societal, religious)	Gendered cultural norms Cultural and religious norms Societal shaming Misconceptions about contraceptive use
Organizational	Unfriendly/judgmental providers Lack of privacy and confidentiality Poor support for youth-friendly health centers
Societal	Peer and media influence Restricted sexuality education Lack of social and community support Poverty level

TABLE 10.5 Factors Affecting Contraceptive Service Use among Adolescents by SEM level

Beyond the challenge of developing a vaccine for COVID-19, clinicians and scientists faced obstacles in addressing vaccine hesitancy among the global population during the pandemic. Researchers conducted an online survey of 592 adults in the United States to examine intentions to obtain a COVID-19 vaccine, using the SEM to determine relations between vaccine intentions and the intrapersonal, interpersonal, institutional, and community-level factors (Latkin et al., 2021). Intrapersonal factors of the respondents who felt negative or ambivalent about becoming vaccinated against COVID-19 included Black race, lower educational attainment, conservative political ideology, no influenza vaccination in the last year, skepticism about COVID-19, and lower engagement in preventative behaviors. Lower levels of perceived social norms (i.e., social rules or typical behaviors and actions) and preventative behaviors were interpersonal factors contributing to negative or ambivalent intention to become vaccinated. Institutional factors such as lower trust in national health agencies also contributed to negative or ambivalent feelings. At the community level, lower perceived likelihood of becoming ill with COVID-19 was associated with negative vaccine intentions. At the time of vaccine development through today, studies that evaluate vaccine hesitance in the context of all SEM levels are important to developing targeted interventions. Targeted interventions are important to supporting vaccine uptake among a sufficient enough percentage of the global population to avoid acquisition, recurrence, or resurgence of vaccine-preventable illnesses such as COVID-19.

Intimate partner violence (IPV) is a global health issue affecting people of all genders and across age groups. In Mexico, nearly 44 percent of women have reported experiencing IPV in their lifetime (Willie et al., 2020). Femicide, the intentional murder of women because they are women, is prevalent in Mexico with an estimated seven women killed each day (Meyer, 2017). These circumstances inspired a research team to investigate access to IPV resources among women in Mexico. A research team collected information via a survey of 950 Mexican women who experienced IPV to determine the socioecological factors that influenced their utilization of community-based supports (Willie et al., 2020). The socioecological levels used to organize the study were individual, partner, family, and community. At the individual level, the team determined that women who were separated or divorced from their partner used 70 percent more IPV resources than women in common-law marriages. Women who knew about more community resources accessed more resources. The severity and manner of the violence also mattered: The women surveyed indicated that they were more likely to use community resources when there was a greater risk of lethality, as well as when a family member of the violent partner was encouraging the abuse. Also, at the relationship level, women being likely to disclose IPV to family and friends increased the resources used. In the community, strong norms regarding resource utilization also supported resource access by women experiencing IPV. The study's results can aid researchers and clinicians in developing targeted interventions to promote IPV services available at community sites, such as emergency medical services, counseling, and hotlines. Additionally, these findings can support the creation of community-wide outreach efforts to strengthen social norms around utilizing support and interventions for IPV.

THEORY IN ACTION

Socio- and Social-Ecological Models

Visit the [CDC website](https://openstax.org/r/uniceforg) (<https://openstax.org/r/uniceforg>) page about the socio-ecological model, view the [UNICEF report online](https://openstax.org/r/Transtheoretical) (<https://openstax.org/r/Transtheoretical>), or review this video [Health Belief and Transtheoretical Models—Fundamentals of Nursing](https://openstax.org/r/transtheoreticalmodels) (<https://openstax.org/r/transtheoreticalmodels>) to see how SEMs can be depicted via illustration. Select a model that you would like to use to conduct a practice application, and then sketch the model on a piece of paper.

Think back to Mo from the chapter opening scenario, and then complete the following exercise.

1. Pick one of Mo's health problems or a condition he may be at risk for (the health problem may be acute, chronic, self-limiting, or requiring treatment and may be individual or a risk for his family/community).
2. Fill in each level of your sketched model with information from his scenario.
3. Add information to each level that you know about barriers and facilitators to health from your other foundational nursing courses.
4. Identify at least one nursing action at each level of the model that can contribute to ameliorating Mo's health problem and to helping clients in the future that may have similar health problems.

The chapter began with a reminder that clients do not exist in isolation and emphasized the interdependence of clients and the environment. Multilayered external influences impact a client's symptoms, health conditions, access to care, quality of care, and opportunities for improved health. Nurses can identify and address the intrapersonal, interpersonal, community, organizational, policy, behavior, genetic, environmental, and social factors that influence the health and well-being of people and populations.

By using SEMs and theories of health behavior, nurses can comprehensively organize and address health. While SEMs are not a replacement for individual-level assessment and intervention in health care, the SEM recognizes the complexity of health status, health promotion, risk reduction, and disease prevention given the interplay between clients and their own situations and environments. SEMs help provide a comprehensive perspective of population health problems and offer insights into solutions across levels. By considering individual, interpersonal, community, and societal factors, the SEMs allow for a more holistic understanding of health problems that can arise from multiple sources. SEMs also acknowledge that individual behavior or choice is not solely responsible for the health outcomes of a particular client or the larger population, collectively. Instead, SEMs emphasize the importance of broader contextual factors and encourage clinicians and researchers to intervene at multiple levels to create sustainable and meaningful health change.

Chapter Summary

10.1 Factors That Influence Health Practices

Nurses are well-positioned to explore the health of clients and communities and to provide meaningful intervention across levels. Nurses need a thorough understanding of health behavior and the factors that may be supportive of or detrimental to health.

Individual client behaviors can greatly influence health, but a person's participation in a healthy lifestyle or motivation to adopt a health habit are not simply a function of wanting or not wanting to be well. Genetics, individual and collective behaviors, environmental and physical influences, medical care, and social determinants influence the health of an individual and community. Further, these factors can impact each other. The ever-changing nature and dynamic relations among these factors make the experience, processes, and outcomes associated with health highly complex.

10.2 Theories and Models of Health Behavior

Nurses may apply theories of health behavior to address the health needs of clients and communities in a thorough and systematic way. Models and theories relevant to the study and change of health behavior include the Social Cognitive Theory, Theory of Planned Behavior, Health Belief Model, Transtheoretical Model/Stages of Change, and Pender's Theory of Health

Key Terms

behavior the way a person acts, the mannerisms they display, and the conduct they employ

federally qualified community health center (FQHC)

clinics providing primary care services to all clients regardless of their ability to pay

genetics the study of how genes, traits, and diseases are passed from one generation to the next

health behavior the actions, habits, activities, policies, and procedures of individual clients, communities, organizations, and governments that can either support or undermine health

intersectionality a concept that considers how disadvantages interact for clients at both an individual level and systems level to identify and describe the inequities, injustices, oppressions, and

Promotion. These allow nurses to explore and recommend interventions to meet the unique needs or circumstances of clients and communities. Nurses can use theories to promote health, prevent disease, and facilitate well-being across populations.

10.3 Core Principles of the Socio-Ecological Model

Clients and communities are unique, dynamic, complex, and constantly evolving. As such, nurses, researchers, educators, and policymakers must analyze and address the health of clients and communities with a broad lens that considers the interaction of many factors. SEMS have been used in health, education, and other disciplines as a guiding framework to evaluate, identify, and improve health and the human experience globally. SEMs provide a way for nurses, clinicians, and others to perform thorough health assessments, identify barriers and facilitators of health, and plan for interventions that can support health across personal, community, and system-wide levels. SEMs can help describe and organize the complex interplay between clients and their environments and specific contextual factors. SEM facilitates a more holistic understanding of health problems and promotes sustainable and effective interventions for supporting population health.

privileges perpetuated by structures including racism, classism, colonialism, sexism, heterosexism, ableism, and others

medical care services rendered by a health care clinician during visits to clinics, offices, hospitals, surgical centers, schools, laboratories, and other places

socio-ecological model (SEM) a model that facilitates the study and organization of how client and community health behaviors and outcomes are affected by personal, situational, community, societal, political, and other contexts

theories used to explain phenomena in a systematic way and to guide thoughts and decision-making processes

Review Questions

- The nurse is providing education to a client with a family history of hypertension. Which statement by the client does the nurse recognize as requiring further teaching about familial risk?
 - "My family history increases my risk for hypertension."
 - "Genetics alone predict my own health and diagnoses."

- c. "The interaction of genetics and environment affects health."
 - d. "Lifestyle factors affect the genetic expression of a disease."
2. The nurse is developing an education program for a client on healthy family nutrition using Pender's Health Promotion Model as the framework. Which client statement indicates to the nurse that the client has a high level of perceived self-efficacy?
- a. "Eating healthy is expensive but within our family budget."
 - b. "I am confident that I can create a healthy weekly meal plan."
 - c. "My children's school encourages healthy lunches."
 - d. "It is hard to find time to shop and prepare healthy meals."
3. The nurse is creating a community program to promote outdoor exercise using Bronfenbrenner's Socio-Ecological Model and is working with town planners to obtain funding and approval for sidewalks and walking and biking trails. Which of Bronfenbrenner's systems is the nurse utilizing?
- a. Microsystem
 - b. Mesosystem
 - c. Chronosystem
 - d. Macrosystem
4. The nurse is working to change negative social beliefs towards breastfeeding in a rural area using the UNICEF Socio-Ecological Model. At which level of this model is the nurse effecting change?
- a. Individual
 - b. Community
 - c. Organizational/institutional
 - d. Policy/system and enabling environments
5. Which situation is an example of a nurse engaging in the Socio-Ecological Model to guide nursing care?
- a. Administering insulin to a client with type 2 diabetes who has seen a worsening of their glycemic control despite taking metformin
 - b. Evaluating the causative factors of an observed increase in the number of grade-school children with newly diagnosed asthma
 - c. Evaluating the impact of lisinopril on a client's blood pressure 3 months after starting the medication
 - d. Planning an education session for a client following surgery with a goal of independently changing the surgical site dressing
6. Which statement by a client with a family history of diabetes indicates an understanding of the genetic component of this disorder?
- a. "Since I have a family history of diabetes, I will also develop diabetes."
 - b. "A family history alone does not mean I will develop diabetes."
 - c. "Eating healthy will not prevent diabetes since it's in my family."
 - d. "Diabetes skips a generation, so I will not get it."
7. Using the UNICEF Socio-Ecological Model, which statement is an example of a community health center working at the organizational level to promote health care?
- a. Teaching a client how to self-administer insulin injections
 - b. Assisting a new mother with breastfeeding
 - c. Treating all clients regardless of their ability to pay
 - d. Lobbying to ensure health care for transgender clients
8. The nurse is caring for a client with diabetes who is having a hard time managing blood glucose levels. Using Bronfenbrenner's Socio-Ecological Model, which factor would the nurse identify as most likely contributing to the client's difficulty managing their diabetes at the exosystem level?
- a. Limited access to healthy food options

- b. Family history of diabetes
 - c. Sedentary job
 - d. Lack of reliable transportation
- 9.** The nurse is counseling a client who is trying to stop smoking. According to the Theory of Planned Behavior, which factor would the nurse recognize as representing risk perception?
- a. The client's partner smokes.
 - b. The client's clothes smell of smoke.
 - c. The client has tried to quit several times.
 - d. The client believes smoking is unhealthy.
- 10.** The nurse is discussing the importance of exercise and eating healthy to a client with hypertension. Which client behavior would the nurse assess as being in the precontemplation stage of the Transtheoretical Model?
- a. The client states they will think about changing their diet.
 - b. The client begins walking three times a week.
 - c. The client meets with a dietitian to learn about healthy eating.
 - d. The client believes that exercise will not lower blood pressure.

CHAPTER 11

Evidence-Based Decision-Making

FIGURE 11.1 Public health initiatives seek to protect and enhance the health of people and the communities in which they live, work, and play. Furthermore, evidence-based practice interventions help implement these initiatives safely and effectively. These protective initiatives help teenagers enjoy life milestones such as graduating from high school. (credit: modification of work “Transit Tech CTE High School Graduation” by Marc A. Hermann/MTA/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 11.1 What Is Evidence-Based Decision-Making?
 - 11.2 Where to Find Evidence-Based Interventions
 - 11.3 Evaluating the Quality of the Evidence
-

INTRODUCTION Amari and Milo are two nurses working in a community health clinic. When they notice an increasing rate of anxiety in teens within the community, they find that the interventions they have used successfully in the past to help clients reduce anxiety, such as providing educational packets and programs regarding anxiety reduction, are no longer eliciting the same results.

To efficiently identify intervention changes they can make to improve outcomes for their teenage clients, Amari and Milo must combine what they find in current research with their extensive experience as client advocates. They will use evidence-based decision-making strategies to develop effective interventions. This chapter walks Amari and Milo through the process of addressing their identified community concern. It also discusses the foundations of evidence-based decision-making, where to find evidence-based information and interventions, and how to evaluate the quality of evidence for use. Furthermore, it explains the importance of evidence-based practice and evidence-based decision-making and specific tools health care providers, including nurses, can use to find and implement evidence-based interventions.

11.1 What Is Evidence-Based Decision-Making?

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 11.1.1 Describe evidence-based decision-making in public health.
- 11.1.2 Describe the steps of evidence-based decision-making.
- 11.1.3 Explain the importance of evidence-based decision-making in public health.
- 11.1.4 Identify tools to support evidence-based public health decision-making.

Health care is designed to help enhance the quality of life for clients through preventative care, maximization of development, care of acute illness, and guidance toward death. Health care providers should use the most up-to-date information on care and treatment plans in these efforts. Evidence-based public health (EBPH) uses the best available current research and information to make decisions that encourage health promotion, disease prevention, and health maintenance. Comprehensively, “EBPH involves accessing the best available research to inform decisions, systematically using data and information systems, applying appropriate frameworks in program planning, engaging the community in assessment and decision-making activities, evaluating the program, and disseminating lessons learned to key stakeholders” (Ruebush, 2019, p. 1). **Evidence-based decision-making** (EBDM) is an essential element of EBPH. A key part of effective practice is applying evidence-based information.

EBDM is similar to **evidence-based practice** (EBP), yet each has its nuances for use in nursing. EBP uses the best available research, clinical experience, and client preferences to inform client-care interventions and evaluation. EBDM is the process of using the most recent research and clinical practice experience to make optimal decisions regarding a policy, practice, and/or program. Foundationally, EBDM extends from EBPH as they both consider the context of the community in conjunction with found evidence to identify and implement appropriate interventions. Additional considerations in the EBDM process include community partner buy-in, feasibility, cost-effectiveness, sustainability, health equity, and public sentiment.

Use of Evidence-Based Decision-Making

Public health is a sector of health care that seeks to protect and enhance the health of people and the communities in which they live, work, and play. Public health decisions and initiatives can have a broad impact, so it is important that they direct health care providers to use the most efficient and effective practices to promote the best possible results. Public health decision makers use EBDM to methodically determine which interventions work best in public health and then share this information with clients and other health care professionals.

The following are fundamental characteristics of EBDM that nurses and health care providers must consider (Cincinnati Children’s Hospital Medical Center [CCHMC], 2023):

- Using the best available peer-reviewed information to make decisions
- Using multiple forms of evidence
- Systematically utilizing data and information systems
- Employing program planning frameworks
- Optimizing community participation in decision-making and assessment, followed by a comprehensive evaluation
- Providing learned information to affected individuals and decision makers
- Implementing successful communication, scientific methods, common sense, and political concerns throughout each step

The National Collaborating Centre for Methods and Tools (NCCMT) has outlined seven steps in the evidence-based decision-making process in public health. [Figure 11.2](#) breaks down these steps—define, search, appraise, synthesize, adapt, implement, and evaluate—to describe the process of EBDM.

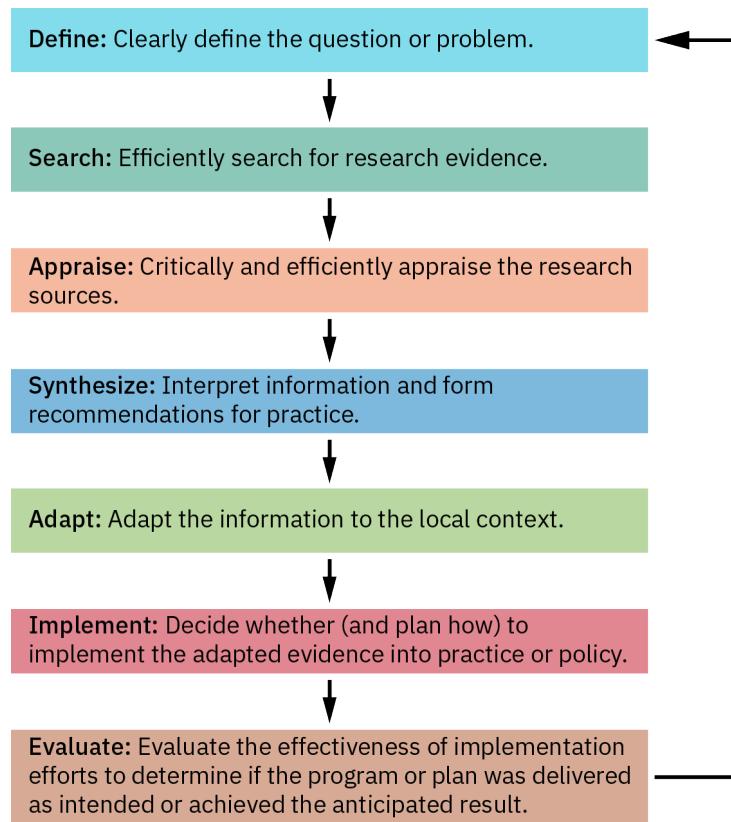

FIGURE 11.2 The National Collaborating Centre for Methods and Tools (NCCMT) has outlined seven steps in the evidence-based decision-making process in public health. These steps include define, search, appraise, synthesize, adapt, implement, and evaluate. (See National Collaborating Centre for Methods and Tools, 2023a; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Defining the Problem

The first step in the EBDM process is to clearly **define** the concern, the problem or question that needs to be addressed. Questions to consider in this step include:

- Who is the target group?
- Which problem or problems need to be solved?
- What is the anticipated plan to implement necessary changes?

The concern is generally formatted as an answerable **PICOT question**. A PICOT question frames the problem in terms of the affected population, the proposed intervention, the groups in the population that will be compared to determine the effectiveness of the intervention, the outcome being studied, and the time frame in which the study will take place. [Table 11.1](#) presents the breakdown of a PICOT question.

P	Population	<p>Outlines the client or client population affected by the problem and with whom the nurse will be in contact. Populations may be defined in multiple ways, some of which include the following:</p> <ul style="list-style-type: none"> • General population: population as a whole • Specific community types: rural or urban dwelling • Population-based descriptors: age, socioeconomic status, risk status, demographics, or literacy levels
I	Intervention	Refers to the change or treatment that will be implemented for the outlined client (population).
C	Comparison	Outlines the reference groups for whom the population in question will be compared. This would be a comparison for the chosen intervention.
O	Outcome	The result that the project will be studying or evaluating.
T	Time	The time interval in which this project will take place, such as when and for how long the intervention will be in place and then compared to the outlined control group.

TABLE 11.1 PICOT Question Breakdown

Identifying each component of a PICOT question helps to clearly define the problem. This question then guides the literature search and the steps in EBDM in public health. As noted, the population may include individuals, communities, or a larger population group. The nurse must decide if the population will be further defined, such as by age, literacy level, or socioeconomic status. Interventions may involve a specific change or treatment, or they may test an approach to health not previously used or studied in this specific population with the outlined concern. The comparison may be a different intervention, often the one currently in practice, or the absence of the proposed intervention. Outcomes will contain measurable results or the aftermath of the implemented intervention. Time outlines how long the intervention will be in place and/or how long outcomes will be measured. [Table 11.2](#) provides example PICOT questions as well as the breakdown of the elements for each question.

Examples	Population	Intervention	Comparison	Outcome	Time
Do early intervention programs provided between 14 and 16 years of age prevent underage drinking among adolescents who live in rural areas within the United States?	Adolescents in rural areas within the United States	Early intervention programs	No early intervention programs	Prevent underage drinking	14–16 years of age
For adults over age 60, does a daily 20-minute exercise regimen reduce the risk of hypertension compared with no daily exercise regimen over 3 years?	Adults over age 60	20-minute daily exercise regimen	No daily exercise regimen	Risk of hypertension	3 years
Are women ages 18–25 years who use intrauterine devices (IUDs) for contraception at an increased risk for developing blood clots compared to women 18–25 years who use oral contraception over 5 years?	Women ages 18–25 years	IUD contraception	Oral Contraception	Risk for blood clot development	5 years

TABLE 11.2 Example PICOT Questions

Searching the Literature

The next step in the process, **searching**, involves reviewing the literature to examine what research is available to address the defined concern and additional data points, which should consider the population in question. A clearly defined question guides nurses' evidence search. [Where to Find Evidence-Based Interventions](#) will further discuss potential sources. Public health may utilize both qualitative and quantitative data or information as they both may apply to this subset of health care, and both may be used to help answer questions in public health. **Quantitative research** contains numbers and objective data to evaluate outcomes and determine results. Quantitative data are expressed by amounts in numerical terms. Often in public health, this is epidemiologic data. **Qualitative research** deals with nonnumerical data such as experiences, attitudes, and behaviors. Qualitative data are expressed in word form, cannot be quantified, and describe perspectives of individuals and populations. Another option for seeking information is a focus group. **Focus groups** are interviews conducted with small groups of participants who share similar traits or interests that will inform the current problem or issue in discussion. These groups are often used to gauge health beliefs, evaluate programs, and provide information fitting the needs assessment.

A community **needs assessment** is an appraisal that identifies a community's strengths and resources. The needs assessment gives reviewers a quick overview of existing systems and policies and areas that need improvement or additional resources. [Assessment, Analysis, and Diagnosis](#) covers conducting a community needs assessment in more detail. Often a windshield survey is part of the community assessment. This is the process of observing the community while driving or walking through it to obtain a visual overview. [Creating a Healthy Community](#) discusses windshield surveys in more detail. An additional part of this needs assessment is identifying any possible community partners. Community partners are those individuals or organizations who are impacted by the project's evaluations and outcomes and thus are interested in the process. While selecting search modalities, health care providers should consider all public health angles, such as issues in the community context, community and political actions and preferences, research, and public health resources. These link closely with the NCCMT model for evidence-based decision-making (see [Where to Find Evidence-Based Interventions](#)). Finally, public health nurses may also obtain information regarding a population's morbidity and mortality rates through [the National Vital Statistics System \(<https://openstax.org/r/nchsnvss>\)](#). Public health care providers may also utilize public health surveillance to obtain data. The four types of broad categories for public health surveillance are noninfectious health conditions, infectious diseases, both infectious and noninfectious diseases and health conditions, and risk factors and exposures (Centers for Disease Control and Prevention [CDC], 2023a).

While searching the literature, nurses must seek data that note the experiences and requirements of marginalized

communities. Since research and scientific work are driven, and thus inhibited, by the perspectives and biases of those who conduct the work, there are notable communities and populations that lack accurate representation within studies, scientific theories, policies, and fact statements. To gather accurate information regarding these marginalized communities, nurses should utilize disaggregated data, or data that has been further broken down into subcategories, such as gender or race, to evaluate health inequities. Additionally, nurses must have a full understanding of the social determinants of health and how these apply to the root causes of inequitable health care access and availability. Ultimately, to identify disparities that may go otherwise unnoticed, data should be analyzed from an intersectional vantage point that recognizes the interdependence of different social identities such as gender, race, ethnicity, age, religious beliefs, developmental abilities and disabilities, and socioeconomic status.

Appraising the Literature

While a significant amount of published research may be available for any given concern, the studies may not be of equal quality. Critically **appraising**, or assessing each study for relevance and credibility, is necessary to ensure the information provided is meaningful, trustworthy, and relevant. Literature that is meaningful will be useful in some way and/or produce important information. Information is considered trustworthy based on its confirmability and the reviewer's confidence in the believability of the information produced in the literature. Finally, relevance considers how pertinent the evidence is to the current problem and population. While there may be literature and evidence that provide valuable information, if the information is irrelevant to the topic in discussion or does not consider similar circumstances for the population, it may not be useful or applicable. This appraisal step should help nurses and other health care providers determine if the methods used in the selected studies or data points are strong enough to use in the problem-solving process. Once each source has been appraised for validity and then reviewed, the information can be synthesized. [Where to Find Evidence-Based Interventions](#) in this chapter will further discuss where to find evidence-based interventions, and [Evaluating the Quality of the Evidence](#) will discuss evaluating the quality of evidence.

In addition to appraising research articles themselves, all other forms of data should be appraised accordingly. Depending on the population, problem, and resources available, some sources may hold a greater weight based on the specific topic and community in question.

Synthesizing the Data

Synthesizing the data involves compiling the information to determine what the research says about the concern. The nurse synthesizing the articles and other data points should consider overlapping themes or messages from different sources. If the research offers conflicting messages, referring back to the appraisal step will be helpful in determining which may be more trustworthy or applicable to the current project. The research that the appraisal process determines to be of the highest quality should hold more weight in decisions. Additionally, in this step, health care providers should synthesize the information gathered from other data sources to identify common themes or attributes of the community or client.

Adapting the Information

The **adapting** step of this process involves determining if this synthesized information can apply to the client (which may be a single person, a family, a community, or a population). In population health, the client is often a community or a whole population, and therefore interventions must work broadly. Referring to the synthesizing step, the nurse should identify actionable steps as possible interventions. In the adapting stage, nurses should consider whether these interventions will be successful or relevant to the client in question and/or if the intervention will need adaptation to work efficiently. Components to consider are the identified problem, the identified intervention, the level of client (single person, family, community, or population), and any other affected individuals that need to be considered, such as organizations or partners in the process. An intervention that is successful in one community may not be successful in another community. Community and population attributes should be considered to determine applicability across clients. These should be considered and discussed during the dissemination phase of the project. Limitations or additional factors to consider should be discussed to help others determine if the intervention(s) can be applied to their specific population.

Implementing the Intervention

The **implementation** stage involves acting on the information and carrying out the determined plan after a possible intervention or action is identified and brainstorming has taken place regarding how this may need to be adapted to

the client in question. In this step, public health nurses will identify actionable and tangible steps for the process. In the public health sector, these often include changes in practice, programs, or policies. This may mean revision of the previously designed practice, program, or policy or delivery of a new version of these components. Client characteristics are crucial at this step as they drive how interventions may be implemented.

Thinking back to the appraisal step, recall that interventions that seem optimal based on research may not be the best option for the current problem. For example, literature might state that frequent time away or vacation would benefit the mental health of teens and young adults. Yet this population may have limited financial means or transportation that make this intervention less feasible. While multiple pieces of evidence may support an intervention, a public health nurse can use their expertise to determine whether an intervention is appropriate for a specific population. If this is discussed in the adapt stage, it may be possible to alter aspects of an intervention to meet the needs of the local context.

Evaluating the Effectiveness of the Plan

Evaluation, the final step in this process, entails determining if the plan accomplished what was intended and, if not, what may need to be changed moving forward. The previously determined indicators are used as an objective measurement of success for the project. Once the effectiveness has been reviewed and evaluated, the team may then determine if they should continue with the intervention(s) as designed or adjust them based on the evaluation.

THEORY IN ACTION

The Importance of Evidence in Decision-Making

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-1-what-is-evidence-based-decision-making>\)](https://openstax.org/books/population-health/pages/11-1-what-is-evidence-based-decision-making)

The NCCMT has created the video “Using Evidence in Public Health Decisions: Why It Matters” to emphasize why using evidence-informed decision-making is essential in public health.

Watch the video, and then respond to the following questions.

1. How does EBDM impact financial decisions regarding implementation of health interventions?
2. Discuss how EBDM can help build the relationship between health care providers and the public.

(See NCCMT, 2017.)

Additionally, the information should be disseminated for use by other health care providers or systems. An essential step in all health care research is sharing results to benefit the population as a whole. Sharing information within the nursing community increases the scope of knowledge within the field and helps to ensure all parties stay up-to-date with policies, practices, programs, and interventions. This may also optimize the cost and quality of care by sharing what has or has not worked in the past. This eliminates multiple steps of trial and error regarding the same topic.

UNFOLDING CASE STUDY

Part A: Evidence-Based Decision-Making

Read the scenario, and then answer the questions that follow.

Recall from the beginning of this chapter that Amari and Milo have noticed an increased rate of anxiety in teens within their community and that the interventions they have used previously are not eliciting the same results. To efficiently identify possible interventions for this population, they know their best option is to use evidence-based practice strategies and that they must first draft a PICOT question as the foundation for their EBP project.

Amari and Milo develop the following PICOT question: *Does daily exercise have an impact on anxiety rates in adolescents compared to those who do not engage in daily exercise over 3 months?*

1. Which of the following components must be covered to be an effective PICOT question?
 - a. Population, interest, cost, outcome, time

- b. Population, intervention, comparison, outcome, time
 - c. Price, interest, comparison, overhead, time
 - d. Price, intervention, company, outcome, time
- 2.** In the PICOT question developed by Amari and Milo, which of the following is the proposed intervention?
- a. Anxiety rates
 - b. Adolescents
 - c. Daily exercise
 - d. 3 months

Importance of Evidence-Based Decision-Making

The intent of health care is to ultimately improve client outcomes with the goal of providing the most effective care available. The EBDM process increases the objectivity of public health decision-making. Historically, health care treatments and skills relied on wisdom passed from one person to another in the form of anecdotes and demonstrations, which may be unreliable. This informal transmission of knowledge, skills, and treatments exemplifies a 19th-century technique that American surgeon William Stewart Halsted called “see one, do one, teach one” (Ayub, 2022). Following this philosophy, nurses should see a skill or technique being completed by another nurse, perform this skill or technique themselves, and then teach a less experienced nurse how to do the skill as needed. While this technique has been relatively effective historically, and while the nursing field as a whole is based on collaboration and knowledge sharing, the technique has flaws. If the original nurse did not perform the skill safely based on the most recent evidence, any nurses who learned the skill from the original nurse would follow the same unsafe pattern. For example, if the first nurse demonstrating insertion of a peripheral intravenous line chooses to rip the finger off their glove to touch the vein site after cleaning the identified site, each subsequent nurse may follow this unsafe process, increasing infection risks to all clients moving forward based on this inappropriate protocol. Similarly, the “see one, do one, teach one” technique relies on each nurse’s memory and the efficacy of each nurse who follows, leading to many opportunities for subjective error. Furthermore, this practice is more difficult to implement on a larger scale such as public health nursing where there is often not an opportunity to directly view the application of a skill.

EBP and EBDM are objective and concrete methods for finding relevant information and applying it to a particular problem. In public health, EBDM is used to ensure that interventions are supported by data and thus should be effective and that they reach the intended population (CCHMC, 2023). It also considers the available resources within the community. The EBDM process provides a compelling rationale for a course of action, whether that action is the continuation of an existing practice or the adoption of a new intervention. The process is thorough and can be replicated. According to NCCMT, evidence-based decision-making in public health should consider research, community health issues (with local context), community and political preference and actions, public health resources, and the public health expertise of decision makers (NCCMT, 2023a) ([Table 11.3](#)). Though there may be more steps involved in EBDM than in historic methods of teaching and decision-making, it enables the nurse to use informed and objective data to make the best and safest decision for the client (Erwin et al., 2020).

Public Health Expertise	Sources of Evidence
Decision makers use their public health expertise and consider evidence from these sources:	<ul style="list-style-type: none"> • Available public health resources • Community and political preferences and actions • Available research findings • Community health issues and the local context

TABLE 11.3 Evidence-Based Decision-Making (See NCCMT, 2023a.)

THEORY IN ACTION

Evidence-Informed Decision-Making

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-1-what-is-evidence-based-decision-making>\)](https://openstax.org/books/population-health/pages/11-1-what-is-evidence-based-decision-making)

The video “NCCMT - URE - Evidence Informed Decision Making - A Guiding Framework for Public Health” presents an overview of the EIDM model. It examines the five overlapping ovals depicted in the model as types of evidence used to inform decision-making. The video uses the example of respiratory illness rates to show how two communities might use other sources of evidence to reach different evidence-informed decisions.

Watch the video, and then respond to the following questions.

1. How might health inequities impact the research phase of the evidence-based decision-making process?
2. Discuss how the unique sources of evidence discussed in the model overlap with one another and with public health expertise.

(See NCCMT, 2018.)

Tools to Support Evidence-Based Decision-Making

Multiple resources and tools are available to assist health care providers in using EBDM. To effectively use these tools and resources, it is necessary to have a strong foundational understanding of the specific client, from a single person up to a whole population. Though much of the information will be gathered from research, to align interventions, these tools must also connect to the designated population and the identified concern for them to prove valuable in the decision-making process. Some tools and resources are designed to support clinical decisions, while others are aimed at working through the EBDM process.

Clinical decision-making support tools are formatted as resources in which health care providers can quickly look up information on clinical practices, assessments, diagnostics, and treatments. One example is UpToDate, which focuses on point-of-care utilizing EBP to make recommendations (Wolters Kluwer, 2023b). This user-friendly, broadly accepted tool provides information for all subspecialties of internal medicine. Another available tool is Lexicomp, which houses detailed drug information in real time (Wolters Kluwer, 2023a). These tools can help health care providers at all levels make and discuss clinical decisions to determine what is currently in practice and help determine what may need to change.

Just as there are support tools available to facilitate clinical decisions, many tools are available to assist with the multistep process of EBDM. Some of these tools help determine a searchable question, while others help with the organization and categorization of identified research articles. Resources to help users define the problem focus on turning the identified concern into an answerable question and identifying key terms to guide an efficient search. Search tools are available to help users sift through data points and document results to track trends and highlighted usable factors. Tools for the appraisal step allow users to organize the data and appraise them accordingly. These tools have prompts and helpful formatting templates to keep appraised information organized. Synthesizing tools then help users pull out relevant information from their search and appraisal process. Adapting tools helps users evaluate the evidence for applicability and usability regarding their current concerns. Approaching the tactical aspect of the process, implementation tools help users plan for and carry out implementation based on their specific circumstance. Finally, evaluation tools and resources provide checklists of key aspects of EBDM and how to review the process that has taken place, starting with defining and moving through implementation (NCCMT, 2023b). To complete the process, there are tools to help with the reflection process of the evaluation phase. For example, McMaster University’s Health Evidence website has multiple tools specifically designed for this process in the public health sector.

TUTORIAL: HOW TO USE HEALTHEVIDENCE.ORG

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-1-what-is-evidence-based-decision-making>\)](https://openstax.org/books/population-health/pages/11-1-what-is-evidence-based-decision-making)

McMaster University’s Health Evidence website offers tools for evidence-informed decision-making. Examples of tools include an EIDM checklist, a resource guide, a search tracker, and search strategies for developing a PICOT question.

Watch the video, and then answer the following questions.

1. What are the three main methods for searching within Health Evidence?
2. Health Evidence utilizes sources at which level of evidence to evaluate the effectiveness of public health interventions? Why is this evidence leveling important?
3. What rating system is used in this database?

By utilizing these tools, nurses and other health care providers can make the complex process of EBDM more attainable by breaking these steps into manageable tasks.

11.2 Where to Find Evidence-Based Interventions

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 11.2.1 Identify examples of databases and registries to locate research and evidence-based prevention services.
- 11.2.2 Identify evidence-based programs that contribute to meeting core public health functions and the 10 Essential Public Health Services.
- 11.2.3 Understand how to use data to inform decision-making in public health nursing.

Once nurses and other health care professionals understand EBP and EBDM and when to use them, the next step is to determine where to find evidence-based practice interventions. The PICOT question guides the search for relevant evidence. This section discusses the different resources nurses may use to find research and to identify evidence-based prevention services. It discusses how the 10 Essential Public Health Services and the social determinants of health are key factors that must inform all public health and population health decision-making.

Databases and Registries

With the vast amount of research available, it is crucial to be efficient while searching for relevant evidence.

Databases, collections of information organized in a systematic method, are helpful during the process of searching for sources of existing literature related to the topic of one's inquiry. Multiple databases are available to assist nurses and other health care providers with the process of selecting evidence-based interventions. [Table 11.4](#) provides examples of commonly used and reliable databases.

Database	Description
Agency for Healthcare Research and Quality (AHRQ) https://www.ahrq.gov/ (https://openstax.org/r/ahrqgov)	Includes evidence summaries and clinical guidelines
Cumulative Index to Nursing and Allied Health Literature (CINAHL) Complete https://www.ebsco.com/products/research-databases/cinahl-complete (https://openstax.org/r/ebsco)	Includes scholarly nursing journal articles
Cochrane Library https://www.cochranelibrary.com/ (https://openstax.org/r/cochranelibrary)	Noted as a core source for EBP; includes systematic reviews that are regularly updated and clinical trials
Joanna Briggs Institute EBP Database https://jbi.global/ebp (https://openstax.org/r/jbiglobal)	Database specifically designed to house EBP articles; includes systematic review, recommended practices, evidence summaries, and tools that can be used in professional EBP

TABLE 11.4 Commonly Used Databases

Database	Description
Medline with Full Text https://www.ebsco.com/products/research-databases/medline-full-text (https://openstax.org/r/ebscoproducts)	Includes articles covering biomedical and health fields; specifically noted for public health and public policy
PubMed (National Library of Medicine) https://pubmed.ncbi.nlm.nih.gov/ (https://openstax.org/r/pubmed)	Provided by the National Library of Medicine; specifically noted for reviews of clinical effectiveness

TABLE 11.4 Commonly Used Databases

In addition to databases, registries are available to provide guidance and information. **Registries** are collections of information regarding people and typically outline a specific condition or diagnosis (National Institutes of Health [NIH], 2023). [Table 11.5](#) provides examples of commonly used registries and resources for nurses.

Registries	Description/Link
Alzheimer's Prevention Registry	Links researchers with those participating in Alzheimer's studies and educating the public by sharing factual and reliable information. https://www.endalznow.org (https://openstax.org/r/endalznow)
Autoimmune Registry	Provides a hub for statistics, research, and client data for all autoimmune diseases. The goal of this registry is to support research and reduce time of diagnosis for clients while establishing appropriate funding for autoimmune disease treatment. https://www.autoimmuneregistry.org (https://openstax.org/r/autoimmuneregistry)
Breast Cancer Surveillance Consortium	Provides a collaborative network of breast imaging and historic registries to improve screening protocols and overall outcomes in the United States. https://www.bcsc-research.org (https://openstax.org/r/bcsc)
Clinical Trials Public Data Share Website	Hosted by the National Institute on Drug Abuse (NIDA), which shares completed trials with investigators and the public. The goal of this registry is to share information and promote new research. https://datashare.nida.nih.gov (https://openstax.org/r/datashare)
Mother to Baby	Provides evidence-based information regarding the safety of drugs and other substances for clients who are pregnant or breastfeeding. While information on exposure to chemicals, herbs, and household products is provided here, more specific observational research is conducted and shared regarding medications and vaccines. https://mothertobaby.org/our-work/ (https://openstax.org/r/mothertobaby)
National Amyotrophic Lateral Sclerosis (ALS) Registry	Compiles research and information provided by clients who have ALS. Direct links to current clinical trials are provided for clients. https://www.cdc.gov/als/GeneralPublic_AboutRegistry.html (https://openstax.org/r/generalpublic)

TABLE 11.5 Commonly Used Registries

Registries	Description/Link
The National Institutes of Health (NIH) Registry List	The National Institutes of Health (NIH) has compiled a list of over 50 registries available for reference. Many of these registries are diagnosis or population specific. This is an excellent resource for nurses and other health care providers seeking specific research to support their EBP intervention. <u>https://www.nih.gov/health-information/nih-clinical-research-trials-you/list-registries</u> (https://openstax.org/r/health)
The Community Guide	A collection of evidence-based findings from the Community Preventive Services Task Force. This informative guide helps nurses and other health care providers find interventions to prevent disease and improve health within businesses, schools, health care organizations, communities, or states. <u>https://www.thecommunityguide.org</u> (https://openstax.org/r/communityguide)

TABLE 11.5 Commonly Used Registries

HEALTHY PEOPLE 2030

Evidence-Based Practices Resource Center

As an additional means of finding EBP tools and information, the Healthy People 2030 initiative offers an [EBP resource center](https://openstax.org/r/healthypeopletools) (<https://openstax.org/r/healthypeopletools>) to support health care providers, public health professionals, and policymakers in incorporating EBP interventions into their communities. These resources center on prevention, treatment, and support services for recovery in substance misuse and mental health disorders.

(See HHS, 2023a.)

Data to Inform Decision-Making in Public Health

As discussed previously, public health nurses and other health care providers must consider multiple data points while searching for background and support, including surveillance, interviews, focus groups, and qualitative or quantitative research articles. While considering this information, nurses must also consider the makeup of their community and the overall functions of public health. The World Health Organization (WHO) is the United Nations agency dedicated to global safety and health. The WHO provides multiple sources to help nurses and other health care professionals achieve their public health goals. Within these resources, the WHO has created Essential Public Health Functions (EPHF) for population health, deemed an indispensable set of actions to achieve the goal of public health. These include (WHO, 2021, p. xii):

1. Monitoring and evaluating the population's health status, health service utilization, and surveillance of risk factors and threats to health
2. Public health emergency management
3. Ensuring effective public health governance, regulation, and legislation
4. Supporting efficient and effective health systems and multisectoral planning, financing, and management for population health
5. Protecting populations against health threats, including environment and occupational hazards, communicable disease threats, food safety, and chemical and radiation hazards
6. Promoting prevention and early detection of diseases, including noncommunicable and communicable diseases
7. Promoting health and well-being and actions to address the wider determinants of health and inequity
8. Ensuring community engagement, participation, and social mobilization for health and well-being
9. Ensuring adequate quantity and quality of the public health workforce
10. Ensuring quality of and access to health services
11. Advancing public health research
12. Ensuring equitable access to and rational use of essential medicines and other health technologies

The function of public health can be summarized as monitoring the health status of the community to identify and

investigate health problems and hazards and to educate and empower people to address them (WHO, 2023). To do so, public health nurses should use multiple forms of data to gather the best available information and apply this to program planning frameworks. This evidence may be research articles, community needs assessments, and statistics on medical risk, morbidity, mortality, and the social determinants of health. Examples of programs that align with the EPHF include cancer prevention and screenings, behavioral risk factor surveillance systems, injury prevention campaigns, sudden infant death syndrome (SIDS) education and prevention programs, and smoking cessation campaigns.

Along with the EPHF, public health services must also be considered in decision-making. In order to achieve public health goals to protect and enhance the health of people and the communities in which they live, work, and play, the CDC has outlined 10 Essential Public Health Services (EPHS) that describe the activities all communities should undertake (CDC, 2023b); see [Foundations of Public/Community Health](#) for more information. Originally published in 1994, the EPHS framework was revised in 2020. Foundationally, the 10 EPHS actively promote systems, policies, and overall environments to enable optimal health for all who seek to eradicate barriers that have resulted in health inequities. Examples of possible barriers to equity in health care are those based on socioeconomic status, education level, age, sex, disability, location, race, and ethnicity. The 10 EPHS strongly state that all members of the community should have just and fair opportunity to attain optimal health and overall well-being. The 10 EPHS center on monitoring the status of the population's health, identifying problems for the population, and educating people accordingly about these problems. The foundations of public health center on creating policies, programs, and interventions to address these problems. Additionally, these steps help outline a pathway for nurses and other health care providers to increase equity across the population by building support and organizations to support a diverse population of clients and health care providers.

The decision-making process must also consider the social determinants of health (SDOH) and how they may impact public health functions. See [Social Determinants Affecting Health Outcomes](#) for more information. The SDOH ultimately contribute to personal and community-wide disparities and inequities. For example, if clients lack access to stores with nutrient-rich foods or the economic means to obtain them, they are less likely to make healthier food choices, which will then likely increase their risk of conditions such as type 2 diabetes, obesity, metabolic disorders, or heart disease. This will impact their quality of life as well as life expectancy.

All of these factors must be considered in the decision-making process as they impact one another and how interventions may ultimately succeed or fail. While one public health nurse may go through the EBDM process and eventually implement a successful program in their specific community, the success of that program may not translate to other communities or populations. For example, in a community where members do not feel safe or where distance and transportation are a concern, a program or intervention that relies heavily on the whole community participating in one physical space may not work well.

Ethical and Equitable Research

If nurses cannot find the information they need in the existing literature, they must do their own research or data extraction to inform their decisions. It is not uncommon for public health nurses to fail to find information fitting a specific population as the literature often has large gaps in representation. A significant factor to consider is **research ethics**. Nurses should already be familiar with the ethical codes that govern nursing practice. These ethical standards direct nursing conduct and allow for trust within the community. Similarly, there are ethical considerations related to research and those who conduct it. Research ethics employ fundamental principles guiding the design and implementation of research. These ethics center on respect for society and participants, resources, and regulation of research to prevent misconduct. These are especially important when research impacts human or animal subjects directly. In this process, there are multiple steps and checkpoints researchers need to make to follow safe channels.

The emphasis on research ethics can be traced to the National Research Act of 1974, which created the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. In response to the unethical research practices used in the U.S. Public Health Service's Syphilis Study, known as the Tuskegee Syphilis Study, this commission identified basic ethical principles that should inform the conduct of biomedical and behavioral research involving human subjects and developed guidelines to ensure that such research is conducted in accordance with those principles (CDC, 2021). The Tuskegee study sought to evaluate the natural course of

untreated syphilis in Black men. Participants were not informed of the study's true nature and thus did not give informed consent. Although penicillin became available as a treatment for syphilis during the study, it was never offered to study participants (Brandt, 1978; CDC, 2022). In 1976, the commission published the [Belmont Report](https://openstax.org/r/ohrpregulations) (<https://openstax.org/r/ohrpregulations>) outlining three basic ethical principles to protect subjects in research studies and/or clinical trials—respect for persons, beneficence, and justice—as well as applications of these principles, including informed consent, assessment of risk and benefits, and selection of subjects (U.S. Department of Health and Human Services [USDHHS], n.d.). These principles work to protect participants from harm, maintain their autonomy, and distribute benefits from the research. Nurses in public health settings must obtain information regarding these steps and follow them accordingly. This may look different depending on the community setting and level of research. Research must be conducted with the goal of promoting health equity. Health equity means allowing everyone to have a fair and just opportunity to attain their highest level of health. As public health considers a group of people or a community as a whole, there are many facets to consider while seeking equity of care.

HEALTHY PEOPLE 2030

Health Equity in Healthy People 2030

As Healthy People has evolved over the decades to reflect the most current science and address the latest public health priorities, it has strengthened its focus on [health equity](https://openstax.org/r/priorityareashealth) (<https://openstax.org/r/priorityareashealth>) (USDHHS, 2023b, para. 1). To find out more about Health Equity within Healthy People 2030, click on the link above and explore.

Equity in health research specifically means all who are affected by research and/or who may benefit from its outcomes should have an equal opportunity to contribute to the research. These equity concerns can exacerbate already-existing health disparities. Nurses must consider their role in protecting the population being researched and promoting equity in research to better serve their communities. Unfortunately, nurses and other health care providers have not always conducted research and trials in an ethical manner. One historical example of unethical medical research is the participation of nurses and doctors in the ill-treatment and execution of tens of thousands of German citizens who were mentally, physically, and emotionally ill both before and during the Holocaust (Copeland, 2021). Another example is the role public health nurse Eunice Rivers Laurie played in the previously mentioned Tuskegee Syphilis Study conducted from 1932 to 1972. Rivers worked for the study, forming a relationship with the men, providing them with transportation and hot meals, and giving them ineffective treatments. As a Black nurse, she was trusted by the men and provided continuity of care for the duration of the study (Brandt, 1978).

INTERVIEW WITH TUSKEGEE STUDY NURSE EUNICE RIVERS LAURIE

[Access multimedia content](https://openstax.org/books/population-health/pages/11-2-where-to-find-evidence-based-interventions) (<https://openstax.org/books/population-health/pages/11-2-where-to-find-evidence-based-interventions>)

This 1972 interview from National Public Radio (NPR) features Eunice Rivers Laurie, a public health nurse who worked for the Tuskegee Syphilis Study for 39 years. Laurie discusses her experience working with patients and answers questions about what patients were told.

Listen to the interview, and then respond to the following questions.

1. What was Nurse Laurie's role as a public health nurse in the Tuskegee Syphilis Study?
2. Why were the men in the study not told they had syphilis, according to Nurse Laurie?
3. If you had an opportunity to ask Nurse Laurie about her experience in the Tuskegee Syphilis Study, what would you ask her?

Research equity in health care is imperative to improve community health and promote social change. Diverse perspectives and backgrounds must be represented in research to broadly provide effective and efficient care to all. Health interventions and policies that do not represent these perspectives and backgrounds are likely to fail to meet the needs of marginalized communities. The biases and perspectives of those conducting research combined with the historical lack of focus on marginalized communities in health care result in notable gaps in information and thus gaps in solutions for these populations. Researchers must identify biases within the data they are using as well as

the power dynamics at each step of the decision-making process to support those who may otherwise be overlooked. Accessibility must be considered within each step of the process regarding appropriate education and information sharing per population. This may mean catering to health literacy level, cultural perspectives, and/or resource availability. Foundationally, participants should receive fully transparent information regarding the intent of the research and how this information will be used. Informed consent incorporates fully transparent direction with the option to opt out at any point. As trusted care providers, nurses have a responsibility to advocate for ethical and equitable research. They have a duty to question practices they feel are not following ethical or equitable standards and to seek to rectify these gaps in research and care. They also have a duty to obtain proper approval before conducting any of their own research and to report any researchers who violate the rights of participants.

WHAT IS PUBLIC HEALTH ETHICS AND WHY IS IT IMPORTANT?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-2-where-to-find-evidence-based-interventions>\)](https://openstax.org/books/population-health/pages/11-2-where-to-find-evidence-based-interventions)

This video reviews basic concepts related to public health ethics.

Watch the video, and then respond to the following questions.

1. What are the four principles of medical ethics?
2. What distinguishes public health ethics from medical ethics?
3. Why do public health and community health nurses need to be aware of issues related to public health ethics?

UNFOLDING CASE STUDY

Part B: Evidence-Based Decision-Making

Read the scenario, and then answer the questions that follow based on all the case information provided in the chapter thus far. This case study is a follow-up to Case Study Part A.

Amari and Milo have developed the following PICOT question: *Does daily exercise have an impact on anxiety rates in adolescents compared to those who do not engage in daily exercise over 3 months?* They are now ready to move on to the next step of the evidence-based decision-making process.

3. After developing their PICOT question, what is the next step that Amari and Milo will take?
 - a. Begin to develop an exercise program for adolescents
 - b. Critically appraise the evidence found in the literature
 - c. Search the literature for supporting research
 - d. Implementing the intervention of daily exercise
4. Amari and Milo are ready to start searching the databases and want to find one specific to public health and public policy. Which database would serve them best regarding these specifications?
 - a. PubMed
 - b. AHRQ
 - c. Cochrane Library
 - d. Medline Full Text

11.3 Evaluating the Quality of the Evidence

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 11.3.1 Demonstrate an understanding of the different levels of evidence.
- 11.3.2 Describe how to evaluate a research study.

In the process of EBP and EBDM, nurses and other health care providers need to understand how to evaluate the quality of evidence. Furthermore, they need to understand why this evaluation should take place. Taking the

necessary steps to evaluate the quality of each piece of evidence ensures that each adds value to the project and helps meet the user's needs and expectations. This process may also help identify gaps in what has previously been researched and/or implemented.

Levels of Evidence

Once evidence has been collected from the literature, the information must then be organized and categorized. To help determine the best and most accurate information available, Johns Hopkins University created the Nursing Evidence-Based Practice (JHNEBP) Model, which utilizes a three-step process for a problem-solving approach to decision-making in clinical practice (Johns Hopkins Hospital, 2017; Johns Hopkins University & Medicine, 2020). Information regarding [the JHNEBP Model \(<https://openstax.org/r/welch>\)](https://openstax.org/r/welch) can be reviewed at the Johns Hopkins website.

THEORY IN ACTION

Johns Hopkins Nursing Evidence-Based Practice Model

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-3-evaluating-the-quality-of-the-evidence>\)](https://openstax.org/books/population-health/pages/11-3-evaluating-the-quality-of-the-evidence)

This video discusses the JHNEBP Model.

Watch the video, and then respond to the following questions.

1. What are two goals of this model, and why are they important for implementation?
2. Discuss the three-phase process used in this model.

(See Henry, 2022.)

EVIDENCE-BASED PRACTICE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-3-evaluating-the-quality-of-the-evidence>\)](https://openstax.org/books/population-health/pages/11-3-evaluating-the-quality-of-the-evidence)

Utah State University Library has created a video to help explain EBP and how it can be used in nursing and medical practice.

Watch the video, and then respond to the following questions.

1. What are the three main elements of evidence-based practice?
2. Why are a client's values and preferences a component of evidence-based practice?

Evaluating the Evidence

After understanding the levels of evidence available during the literature review, the next step is to appraise the evidence. The three main steps in evidence appraisal are identifying the type of evidence, determining the evidence level and strength, and then evaluating the quality of the evidence.

Evidence appraisal entails reviewing acquired information and systematically assessing its intended audience, purpose, relevance, applicability, validity, and reliability. The **intended audience** is the demographic that the writer or writers expect to read and interact with the information. The **purpose** of an article, often presented in a purpose statement early in the article, identifies the reason for the project or study. An article's statement of purpose can help a nurse to quickly identify whether the article will help answer the research question. Furthermore, the article should be reviewed for **relevance**, meaning how closely the source's elements relate to the research question and whether the results can be applied to the intended population. **Applicability**, or how well the results and data pertain to a broad or specific population, is an important piece of appraisal. **Validity** refers to the degree to which the information within the article is factual. This is sometimes referred to as accuracy or credibility in research articles. Correspondingly, **reliability** is the extent to which results can be reproduced if research is completed under the same conditions. [Figure 11.3](#) demonstrates the search pyramid tools researchers use to rank the evidence they gather. Each level of evidence pulls from the research obtained at lower levels, meaning the highest and most

synthesized information is at the top of the pyramid. The highest quality, most reliable evidence from the highest level of the decision pyramid is most likely to support effective action and should be used first.

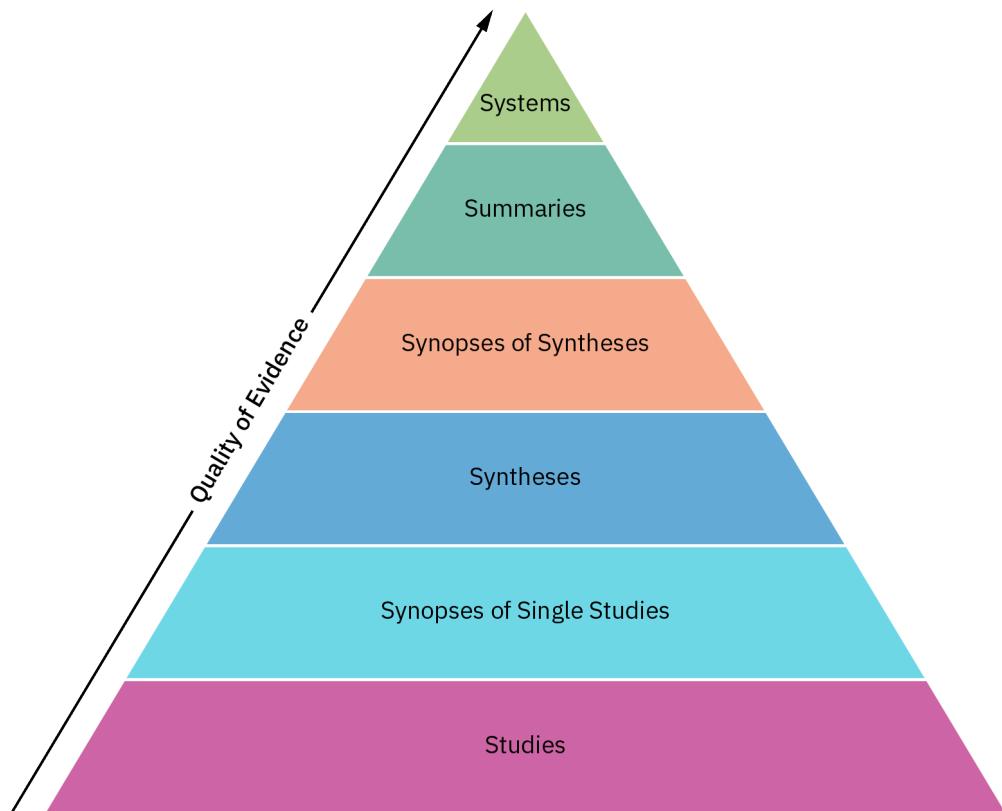

FIGURE 11.3 The National Collaborating Centre for Methods and Tools provides the 6S search pyramid outlining evidence from the lowest to the highest level. (See National Collaborating Centre for Methods and Tools, 2023c; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

UNFOLDING CASE STUDY

Part C: Evidence-Based Decision-Making

Read the scenario, and then answer the questions that follow based on all the case information provided in the chapter thus far. This case study is a follow-up to Case Study Part B.

Using research databases, Amari and Milo found four quantitative studies and three qualitative studies regarding exercise and mental health. Additionally, they surveyed the community to identify components of community exercise programs. This survey included physical locations, cost, and general attendance of these classes and programs. They also spoke with the local school systems to determine how physical education is incorporated into the high school curriculum. Amari and Milo must now appraise the evidence in order to select which data points to use and to what degree.

5. Which factor should Amari and Milo consider in their appraisal of the evidence they found?
 - a. The reputation of the researcher
 - b. The cost of the study
 - c. The length of the study
 - d. The trustworthiness of the study

6. During their appraisal of the evidence, which type of study would provide Amari and Milo with the highest quality of evidence?
 - a. Randomized controlled studies
 - b. Anecdotal reports

- c. Cross-sectional studies
- d. Summaries

CONVERSATIONS ABOUT CULTURE

Minority Representation in Medical Research

[Access multimedia content \(<https://openstax.org/books/population-health/pages/11-3-evaluating-the-quality-of-the-evidence>\)](https://openstax.org/books/population-health/pages/11-3-evaluating-the-quality-of-the-evidence)

This PBS video outlines gaps in representation of racial and ethnic groups in clinical trials and medical research. These gaps limit the amount of information available about diverse populations, which can skew perspectives on care. Nurses in public health must find ways to combat these gaps.

Watch the video, and then respond to the following questions.

1. How can public health nurses help mitigate the discrepancies in representation currently seen in medical trials and research?
2. Reverend Alvin Hathaway states, “That’s not really bias, that’s just accessibility” when discussing funding slanted toward a European data set. What does this mean? How can public health nurses help to broaden this data set?

Each article or source identified in the literature review of a project should be appraised considering the aspects discussed above. [The Johns Hopkins Toolkit \(<https://openstax.org/r/upstate>\)](https://openstax.org/r/upstate) provides a guide to evidence level and quality, which can facilitate this process. Once this appraisal has been completed, the sources can be categorized and ranked to determine which ones may be helpful to use as a foundation for the research ahead. Nurses should use this process to identify strong research that can support the outcomes of their EBP intervention.

CASE REFLECTION

The Final Step in the EBDM Process

Read the scenario, and then respond to the questions that follow.

Throughout this chapter, Amari and Milo have applied the EBDM process to a concern in their community. This segment reveals the outcome of their process. Read the scenario, and then respond to the following questions.

After synthesizing the data, Amari and Milo note that consistent interventions discussed to support mental health in adolescents are regular exercise, appropriate sleep, and relaxation techniques. Specifically, the literature supports structured exercise classes and group movement as a successful method to reduce adolescent anxiety.

While the research supports specific interventions, as public health nurses, Amari and Milo know they need to also take into consideration the NCCMT Model for evidence-based decision-making as it incorporates research, community health issues in the local context, community and political preferences and actions, public health resources, and public health expertise. With that, their assessment notes the limited access to workout facilities such as public gyms for many of the adolescents in the community. Additionally, they note a high price for membership compared to the average family income. They are also aware that many adolescents in the community work to help support themselves and their families. This not only limits their time availability but also speaks to the additional monetary strain. After speaking with a representative of the public school system, they note that physical education classes are optional for high school juniors and seniors. They find many students opt out of this class as their other option is early release or study hall.

Due to all these factors, the nurses identify that although the literature is clear on a specific intervention for exercise, it may not be the best option for their current community. Instead, the two decide they can still implement interventions for daily exercise that consider these community factors.

This leads them to the adapt phase. They decide to implement the following interventions:

Offer free daily classes at the community health center lead by volunteers. These classes will be offered at two different times each day and will be available to all adolescents within the community.

Compile a list of free exercise resources on the health department website that adolescents can use directly by streaming them at home, if possible, or in the community center with free internet. Additionally, Amari and Milo have worked with the high school and obtained support for two computers to be used for this resource that will be available for students during their study hall.

Each participant who attends a class will sign in to track use of this resource. Those who access the electronic resources will have a unique log-in passcode. These will be used to track the amount of exercise over 3 months for each participant. This data will then be looked at in comparison to the level of anxiety reported by adolescents in the community.

After three months of implementation, Amari and Milo review the rates of exercise and rates of anxiety for adolescents in the community. They find a decrease in anxiety for those who participated in exercise at least 5 times a week. Due to these results, the nurses begin brainstorming how they can expand these interventions. They will support daily exercise but note that activity at least 5 days a week helps reduce anxiety. They plan to obtain data for three more months and then disseminate their results at that time.

1. Identify and discuss the last step in the public health decision-making process. What takes place during this step, and why is it important?
 2. Do you agree with the implemented interventions? Why or why not?
 3. What other interventions would you propose? How would you ensure your recommendations are evidence-based? Provide at least two alternative interventions with resources cited for support.
-

Chapter Summary

11.1 What Is Evidence-Based Decision-Making?

Evidence-based decision-making in public health is an objective method that involves seven steps: define, search, appraise, synthesize, adapt, implement, and evaluate. The first step is to define the problem, usually as a PICOT question. This leads the way for the rest of the process. Often, interventions outlined in research may not fit the designated community and require adaptation. The NCCMT's Model for evidence-based decision-making assists with this process.

11.2 Where to Find Evidence-Based Interventions

Databases and registries are potential sources of reliable, evidence-based interventions. Additional frames of reference include the WHO's Essential Public Health Functions (EPHF) and the CDC's 10 Essential

Key Terms

adapt a part of the EBDM process that determines if synthesized information can apply to the client (which may be a single person or a community) in discussion

applicability when evaluating the evidence, assesses how well the study's results and data pertain to broad or specific populations

appraise a part of the EBDM process that involves critically assessing each study for relevance and credibility to ensure the information provided is meaningful, trustworthy, and relevant

database collection of information organized in a systematic method that is helpful when searching for sources of existing literature related to the topic of inquiry

define a part of the EBDM process that clearly identifies the problem or question to be addressed

evaluation a part of the EBDM process that determines the effectiveness of the implemented plan by deciding if it accomplished what was intended and, if not, what may need to be changed

evidence appraisal systematic critique of acquired information to review its purpose, intended audience, relevance, validity, and applicability to the specific question being asked

evidence-based decision-making (EBDM) the process of using the most recent research and clinical practice experience to make optimal decisions regarding a policy, practice, and/or program

evidence-based practice (EBP) using the best

Public Health Services (EPHS). Research ethics are fundamental principles that guide the design and implementation of research. Nurses must consider their role in protecting the population being researched and promoting equity in research to better serve their communities.

11.3 Evaluating the Quality of the Evidence

Evaluating the quality of each piece of evidence ensures that each adds value to the project and helps meet the user's needs and expectations. This process may also help identify gaps in what has previously been researched and/or implemented. Evaluating the quality of evidence involves reviewing the acquired information and systematically assessing its intended audience, purpose, relevance, applicability, validity, and reliability.

available research, clinical experience, and client preferences to inform patient-care interventions and evaluation

focus groups interviews conducted with small groups of participants who have similar traits or interests; informs the current problem or issue in discussion

implementation a part of the EBDM process that involves acting on research information to carry out the determined plan

intended audience demographic that a writer or writers expect to read and interact with an article

needs assessment an appraisal that identifies strengths and resources from the community and gives reviewers a quick overview of existing systems and policies and areas that need improvement or additional resources

PICOT question as part of the EBDM process, involves the problem or concern being formatted to address the population, intervention, comparison, outcome, and time frame in the form of an answerable question

purpose component of a research study or article that identifies the reason it was conducted; often identified as a purpose statement

qualitative research deals with nonnumerical data such as experiences, attitudes, and behaviors; expressed in word form, cannot be quantified, and describes perspectives of individuals and populations

quantitative research contains numbers and objective data to evaluate outcomes and determine

results; expressed by amount in numerical terms

registries collections of information regarding people, typically outlining a specific condition or diagnosis

relevance how closely source elements match the current question and whether the results can be applied to the population in question

reliability the extent to which results can be reproduced if research is completed again under the same conditions

research ethics fundamental principles guiding the design and implementation of research centering on

respect for society and participants, resources, and regulation of research to prevent misconduct

search a part of the EBDM process that involves reviewing the literature to examine what research is available to address a concern

synthesize a part of the EBDM process that involves compiling information, looking for specific trends in data to determine what the research says about the concern or issue

validity how factual the information within the article is; sometimes referred to as accuracy or credibility in research articles

Review Questions

1. The nurse is discussing the importance of evidence-based decision-making (EBDM) with a group of students. Which statement by a student indicates understanding of this process?
 - a. “EBDM is a one-step process to make clinical decisions.”
 - b. “EBDM utilizes subjective decision-making.”
 - c. “EBDM uses interventions with replicable results.”
 - d. “EBDM relies on past nursing experiences.”

2. Which information is the nurse assessing when appraising the applicability of a research article?
 - a. The intended audience of the article
 - b. The degree to which the results relate to a specific population
 - c. The accuracy or credibility of the research
 - d. The purpose of the research

3. While conducting a literature review for an evidence-based project, the nurse recognizes that which type of study represents the lowest level of evidence?
 - a. Case reports
 - b. Cohort studies
 - c. Randomized control trials
 - d. Cross-sectional studies

4. A nurse has developed the following PICOT question: In adult men, is zinc supplementation as effective as vitamin C supplementation in reducing the length of respiratory viral infections over six months? The nurse identifies “zinc supplementation” as which part of the PICOT question?
 - a. Population
 - b. Intervention
 - c. Comparison
 - d. Outcome

5. A public health nurse has developed a research question and searched the literature for supporting evidence. In which step of evidence-based decision-making would the nurse compile the research findings and identify specific trends in the data?
 - a. Defining the problem
 - b. Synthesizing the literature
 - c. Appraising the literature
 - d. Adapting the information

6. Which database would the public health nurse use when conducting research to locate regularly updated systematic reviews?
 - a. Cochrane Library

- b. Agency for Healthcare Research and Quality (AHRQ)
 - c. Medline with Full Text
 - d. Cumulative Index to Nursing and Allied Health Literature (CINAHL)
7. Which action will the public health nurse perform when conducting an ethical community study?
- a. Require each participant who provides informed consent to complete the study.
 - b. Obtain informed consent only from vulnerable populations.
 - c. Get informed consent only if the risks of participating in the study are high.
 - d. Obtain informed consent from each participant in the study.
8. The nurse is developing a PICOT question to study methods to promote smoking cessation in high school students in a rural community. Which statement identifies the targeted population?
- a. The rural community
 - b. Community members who smoke
 - c. All high school students in the community
 - d. High school students in the rural community who smoke
9. Which type of study will the nurse use to understand the experiences of an immigrant group in the community?
- a. Qualitative
 - b. Randomized control
 - c. Needs assessment
 - d. Quality improvement
10. Which activity would the nurse perform during the evaluation phase of evidence-based decision-making (EBDM)?
- a. Carrying out the proposed plan
 - b. Deciding if the evidence is applicable to the population
 - c. Determining the effectiveness of the plan
 - d. Compiling the data

CHAPTER 12

Epidemiology for Informing Population/ Community Health Decisions

FIGURE 12.1 Public health professionals often bring vaccine clinics to the community as a primary method to prevent disease and improve the health of the community. (credit: modification of work "Public Health at Work" by Thad Zajdowicz/Flickr, Public Domain)

CHAPTER OUTLINE

- 12.1 Epidemiology Defined
- 12.2 Historical Perspective
- 12.3 Epidemiological Approaches
- 12.4 Types of Study Design
- 12.5 Epidemiologic Measures
- 12.6 Communicating Inferences from Epidemiologic Data
- 12.7 The Role of Epidemiology in Scientific Decision-Making and Policy Development

INTRODUCTION Did you ever wonder where clinical guidelines originate? For example, screening for lung cancer with computed tomography is recommended for adults 50–80 years of age who have a 20-pack-a-year smoking history. On what evidence is this recommendation based? Recommendations like this one are the result of epidemiological study. This chapter will introduce basic concepts of epidemiology, how it has evolved, and how it is used today, focusing on the application of epidemiology to public health practice.

12.1 Epidemiology Defined

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.1.1 Define epidemiology.
- 12.1.2 Explain the objectives of epidemiology.
- 12.1.3 Examine the role of epidemiology in public health.

Epidemiology is the scientific study of the distribution and determinants of diseases and health outcomes in populations in order to develop methods of controlling health problems, limit the consequences of illness, and maximize health. Epidemiology relies on a methodical and unbiased approach to data collection, analysis, and interpretation. This multidisciplinary science draws from the biologic, economic, social, and behavioral sciences and the scientific disciplines of biostatistics and informatics. Epidemiology is described as the basic science of public health because it provides the foundation for overseeing public health interventions (Centers for Disease Control and Prevention [CDC], 2012).

Epidemiology seeks to establish causal factors for **health events**, defined as disease, injury, or death (CDC, 2012). Epidemiologists define the populations to be studied. These populations may be as small as one town or as large as an entire country. They may be selected based on geography, biologic factors such as gender or age, or social factors such as race, lifestyles choices, or income level. Epidemiologists view the entire health spectrum, from safety and injury prevention—such as bicycle or motor vehicle safety—to disease prevention and control.

Epidemiological Objectives

Epidemiology is founded on principles of health, safety, and wellness. It focuses on the overall health and welfare of populations of individuals, studying patterns of disease frequency and distribution and determinants of health and illness (Frérot et al., 2018). Epidemiological objectives include (Celentano & Szklo, 2019):

- Identifying the causes of disease or factors that increase an individual's risk for disease
- Identifying how diseases are transmitted
- Determining the extent of disease in a community or specified population
- Evaluating preventive and therapeutic measures of health care delivery
- Providing the foundation for developing public policy regarding disease prevention and health promotion

Application of Epidemiology to Public Health

By identifying causes and risk factors for disease development, public health nurses can use evidence-based information to intervene early to reduce morbidity and mortality. For example, in 1950, epidemiologists Doll and Hill demonstrated a causal link between the development of lung cancer and smoking cigarettes. Their studies laid the foundation for public health initiatives to decrease rates of cigarette smoking. In 1965, 42 percent of adults in the United States smoked cigarettes, but by 2021 the rate had fallen to 11.5 percent (CDC, 1999; CDC, 2023).

Epidemiologic studies can identify how diseases are transmitted, enabling public health nurses to advocate for appropriate control programs. Diseases can be transmitted from person to person or from nonhuman sources, such as ticks or mosquitoes, to the human population. Well-designed epidemiologic studies have demonstrated how major communicable diseases are transmitted. For example, measures to ensure staff and client safety where tuberculosis may be present are based on the 1956 work of epidemiologists Riley and Wells (Thomas, 2020).

Determining the prevalence and extent of disease in a community is another function of epidemiology. Public health nurses can use this information to prepare for communicable disease outbreaks. For example, by using epidemiological statistical models, public health nurses can prepare adequate vaccine supplies and plan health services needed to respond to seasonal influenza outbreaks.

Public health nurses can also use evidence-based epidemiological information in health promotion education. For example, epidemiologists study whether screening improves survival for men with prostate cancer. Nurses can use the results of those epidemiological inquiries to assist them in educating at-risk communities. Epidemiological studies, such as studies seeking to discover whether high levels of radon in homes causes disease, can also inform nurses' work to advocate for public policy at the local, state, and federal levels.

12.2 Historical Perspective

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.2.1 Describe the historical origins of epidemiology.
- 12.2.2 Identify key figures influential in the field of epidemiology.
- 12.2.3 Examine the contribution of nursing to the field of epidemiology.

The origin of epidemiology has been traced to physician Hippocrates' "On Airs, Waters, and Places." This medical textbook, written in ancient Greece circa 400 BCE, details Hippocrates' belief that disease was caused not by the supernatural but instead by environmental factors and his recommendations that healers observe their patients' lifestyle choices (Kleisiaris et al., 2014). Several important figures followed Hippocrates in the evolution of epidemiology; this chapter will highlight four of the most influential: Edward Jenner, Ignaz Semmelweis, John Snow, and Florence Nightingale.

Edward Jenner (1749–1823) developed an immunization against smallpox that ultimately resulted in its eradication (Riedel, 2005). Smallpox affected all levels of society in 18th-century Europe, killing 400,000 people each year. Many of those who survived went blind (Louten, 2022; Riedel, 2005). The case-fatality rate in London was estimated to be as high as 80 percent in infants and 60 percent in children and adults. Edward Jenner had heard that dairy maids seemed to be protected from smallpox after having contracted cowpox. He theorized that inoculating a person with matter from a cowpox lesion would provide them with protection from smallpox. To test his theory, Jenner inoculated a young boy with matter from the cowpox lesions of a dairy maid and then inoculated the child 6 weeks later with matter from a fresh smallpox pustule. Jenner's experiment seemed to work: the child did not contract the disease. This is the first recorded scientific attempt to control an infectious disease by the deliberate use of vaccination, a method that eventually saved millions of humans from death and disability worldwide (Celentano & Szklo, 2019). On May 8, 1980, the World Health Assembly recommended ceasing smallpox vaccination as the world was smallpox-free (Riedel, 2005). Jenner operated solely on observational data that provided the basis for a preventative intervention.

In the early 19th century, puerperal fever (childbed fever) had mortality rates as high as 25 percent among women shortly after childbirth (Celentano & Szklo, 2019). Theories about its causes included solar and magnetic influences and air. In 1846, Ignaz Semmelweis (1818–1865), a physician specializing in obstetrics, was put in charge of the General Hospital in Vienna where there were two obstetrical clinics, the First and Second. The First Clinic was staffed by physicians and medical students and the Second Clinic by midwives. Semmelweis noticed the mortality rates in the two clinics were very different; in 1842, the rate in the First Clinic was more than twice as high as the rate in the Second Clinic (Celentano & Szklo, 2019). Knowing that physicians and medical students began their days performing autopsies before providing care in the First Clinic and that midwives did not perform autopsies, Semmelweis suggested mortality was higher in the First Clinic because the hands of physicians and students were transmitting disease from the cadavers to the women in labor.

In 1847, Semmelweis's colleague contracted an infection after being accidentally punctured while performing an autopsy on a woman who had died of childbed fever. An autopsy on Semmelweis's colleague demonstrated similar pathology to the women dying from childbed fever, confirming Semmelweis's suspicions regarding the transmission of the disease (Celentano & Szklo, 2019). Based on these causal findings, Semmelweis implemented a handwashing policy for physicians and students in the First Clinic. In 1848, mortality in the First Clinic dropped to rates comparable to those in the Second Clinic. Reinforcing this causal relationship, when Semmelweis was replaced by another obstetrician, the handwashing policy was eliminated, and mortality rates rose again in the First Clinic. Semmelweis's findings and recommendations had a global impact on the practice of medicine. His observations and interventions came before there was any knowledge of germ theory, proving it is possible and may be effective to implement a prevention strategy without knowledge of the exact cause of disease (Celentano & Szklo, 2019).

British physician John Snow (1813–1858) is often considered the "father of field epidemiology" (CDC, 2012) for his work translating epidemiologic observations into public policy during the 1850s cholera epidemic in London. His work illuminates the sequence from descriptive epidemiology to hypothesis generation to analytic epidemiology (hypothesis testing) to application. Snow approached his investigation of the source and transmission of the disease by examining where the people affected with cholera lived and worked. He marked each residence on a map of the

area. This type of map is called a **spot map**, and it shows the geographic distribution of cases of illness or disease. On this map, Snow also marked the location of water pumps to look for a relationship between the residences with cases of cholera and the location of pumps. He noticed a pattern of affected residences clustered around Pump A, more so than around Pumps B or C. He concluded that Pump A was the primary source of water and most likely the source of cholera infection. Snow gathered information on where those affected with cholera obtained their water and found that, confirming his suspicions, Pump A was the one common factor. After presenting these findings, the handle of the pump was removed, and the outbreak ceased (CDC, 2012). [Visit this site \(<https://openstax.org/r/ucla>\)](https://openstax.org/r/ucla) to see what a spot map looks like.

FIGURE 12.2 Florence Nightingale was named “the Lady with the Lamp,” as she worked tirelessly to care for soldiers during the Crimean War, making her rounds during the night after the medical officers had retired. She spent her days organizing, leading, and fighting with military officers to make sanitary changes. (credit: “Florence Nightingale during the Crimean War” by Illustrated London News/Wellcome Collection, CC BY 4.0 International)

Florence Nightingale (1820–1910), long considered the founder of professional nursing, is also considered the first nurse epidemiologist. Nightingale devoted her life to the prevention of illness and death and used statistical methods to visualize data and bring about health reforms (Bradshaw, 2020; Fee & Garofalo, 2010; McDonald, 2014). In 1854 she joined a group of nurses aiding troops in Crimea (Figure 12.2). She saw the suffering in the hospital barracks—not due to battle injuries, but due to the rodent-infested buildings, filthy environment, and overflowing sewers. Soldiers suffered from wounds, dysentery, malnutrition, cholera, typhus, and scurvy, with a high mortality rate (Bradshaw, 2020; Fee & Garofalo, 2010; McDonald, 2014). Nightingale gathered data and documented the results of her sanitation reforms to illustrate the unnecessary deaths in military hospitals. After the war, she continued documenting negative health outcomes associated with poor sanitation. She eventually convinced the government to implement her sanitary reforms and continued to track the data (Bradshaw, 2020; McDonald, 2014). Nightingale monitored disease mortality rates, used a research framework to study the distribution and patterns of disease in a population, used applied statistical methods to visualize the data, and published statistical reports to gain the support of politicians and powerful people to bring about public health reforms that ultimately created changes in hygiene and treatment of clients. As one of the first to apply statistics to health care, Florence Nightingale was a pioneer who brought the field of public health to international attention and became the first woman to be awarded Britain’s Order of Merit in 1907 (Fee & Garofalo, 2010).

12.3 Epidemiological Approaches

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.3.1 Discuss the interaction and interdependence of agent, host, and environment (epidemiologic triad) in communicable disease transmission.
- 12.3.2 Explain the components of the natural history of disease.
- 12.3.3 Describe the chain of infection and implications for understanding causative factors.
- 12.3.4 Discuss the web of causation.

The **epidemiological triad** posits that disease is caused by the interaction between a susceptible host, an external agent, and an environment that brings the host and agent together (CDC, 2012). It reflects the idea that health is not the result of one factor but rather results from the interaction of these elements (Celentano & Szklo, 2019).

The **host** can be an individual, a family, a group of high-risk individuals, or a community. Host factors include immunologic characteristics such as prior history of infection or immunization; modifiable factors such as exercise level, nutrition, and lifestyle; and non-modifiable factors such as age, race, and genes.

The **agent** is something that can cause a health issue, and the environment is the context within which the agent and host interact. Agents are classified into five categories: physical (trauma, radiation, heat), chemical (pollutants, medications, drugs, alcohol, smoke), nutritional (lack of or excess of), psychosocial (stress, social isolation), and biologic (bacteria, viruses, arthropods, toxins). The **pathogenicity** of the agent, or its ability to cause disease, influences disease onset. An agent must be present for a disease to occur, but the presence of an agent does not always cause disease; a variety of factors influence whether exposure to an agent will result in disease (CDC, 2012).

Environmental factors include the biologic environment of plants, animals, and toxins, including *vectors* (life forms such as mosquitoes or ticks that carry infectious agents) and the *reservoirs* where vectors and infectious agents are normally found. Other environmental factors are physical and social in nature, such as neighborhoods, housing, temperature, altitude, presence of crowding, air pollution, radiation, water quality, and noise.

The epidemiological triad ([Figure 12.3](#)) shows how host, agent, and environment can interact to cause disease. (Note that this model is incomplete for diseases that have other kinds of contributing causes, such as cardiovascular disease.) A good example of the epidemiological triangle is cholera, the diarrheal illness that John Snow linked to contaminated water. In the John Snow example, the host was the susceptible individual who consumed the contaminated water. The agent was *Vibrio cholerae* bacteria. The environment was the contaminated water system.

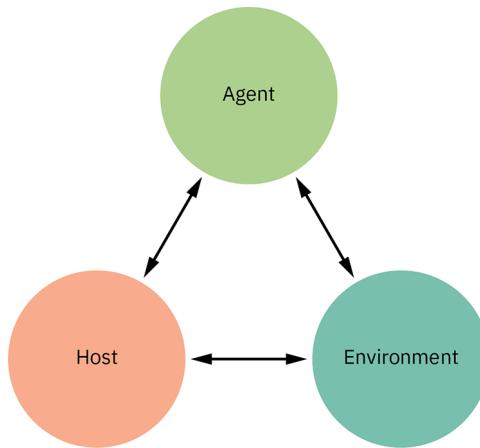

FIGURE 12.3 The epidemiological triad demonstrates the three factors that interact to cause illness. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Natural History of Disease

In the absence of treatment, diseases in individuals follow a natural progression, referred to as the **natural history of disease** (CDC, 2012). The natural history of disease encompasses events that occur before, during, and after the conclusion of a disease. The process involves multiple interactions between host, agent, and environment.

The natural progression of a disease has four stages: susceptibility, subclinical (preclinical) disease, clinical disease, and resolution (recovery, disability, or death) (CDC, 2012) ([Figure 12.4](#)). The initial interactions between agent, host, and environment occur during the susceptibility stage, or the pre-pathogenesis period, during which primary prevention measures could be implemented to prevent onset of the disease. Pathogenesis (onset and progression of a disease) begins when the host has clinical disease, and secondary prevention measures focus on early diagnosis and treatment to limit resulting disabilities (CDC, 2012).

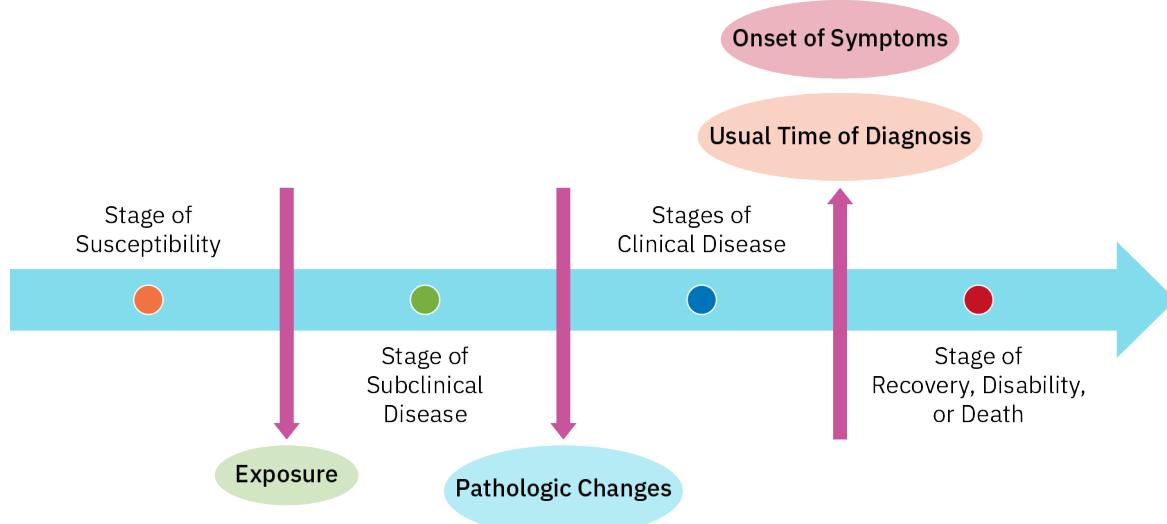

FIGURE 12.4 There are four stages of disease progression: susceptibility, subclinical (preclinical) disease, clinical disease, and resolution (recovery, disability, or death). (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The process begins with the **susceptibility stage**, or exposure of a susceptible host. In communicable diseases, the exposure is to a microorganism. In noncommunicable diseases like cancer, the exposure could be a factor that instigates the process, such as tobacco smoke (lung cancer). Once the disease process begins, pathologic changes occur without the host being aware of them. In this **subclinical disease stage**, individuals have no overt symptoms. In infectious diseases, this stage includes an incubation period during which the pathogen multiplies to produce clinical symptoms. In noninfectious disease, it includes a latency period (the time from exposure to onset of symptoms). The latency period may be as brief as seconds for acute hypersensitivity (allergic) reactions or as long as decades for certain chronic diseases. In the **clinical disease stage**, signs of the disease develop, and diagnosis may occur. In the resolution stage, the disease may end with a return to health, a chronic form of the disease with limitations, or death (CDC, 2012).

In the subclinical stage, although disease is not yet apparent, there may be pathologic changes that can be detected with laboratory evaluation of blood work, radiographic evidence, or other screening methods. Many screening programs aim to identify the disease process early, as intervention in the early stage is often more effective than after the disease has progressed to symptoms (CDC, 2012).

The onset of symptoms marks the clinical disease stage in which most diagnoses occur. Some individuals may never progress to clinical disease, while others may have mild to severe illness. The severity of a disease is impacted by the infectivity, pathogenicity, and virulence of infectious agents. With any infectious disease, there are often many undiagnosed cases, as there will always be individuals who never progress to the clinical stage.

Individuals who have only subclinical disease but are infectious are termed **carriers**. Carriers are individuals with incubating disease or preclinical infection. For example, an individual infected with measles becomes infectious days before symptoms appear. Carriers are usually unaware they are infectious and are more likely to spread infection than those with obvious illness (CDC, 2012). Chronic carriers carry pathogens after recovering from the initial illness and may carry these pathogens for months or years. Examples include chronic carriers of hepatitis B virus and *Salmonella Typhi*, the causative agent of typhoid fever. Typhoid Mary, Mary Mallon, was an asymptomatic chronic carrier of *Salmonella Typhi* who, as a cook in the early 1900s, unknowingly infected many individuals in New York before her condition was identified and she was quarantined (CDC, 2012).

Chain of Infection

The **chain of infection** is an epidemiological model that allows for a more complex and nuanced interplay between the host, agent, and environment of the epidemiological triad ([Figure 12.5](#)). The **agent** is the virus or bacteria itself. The other elements of the chain of infection are discussed below.

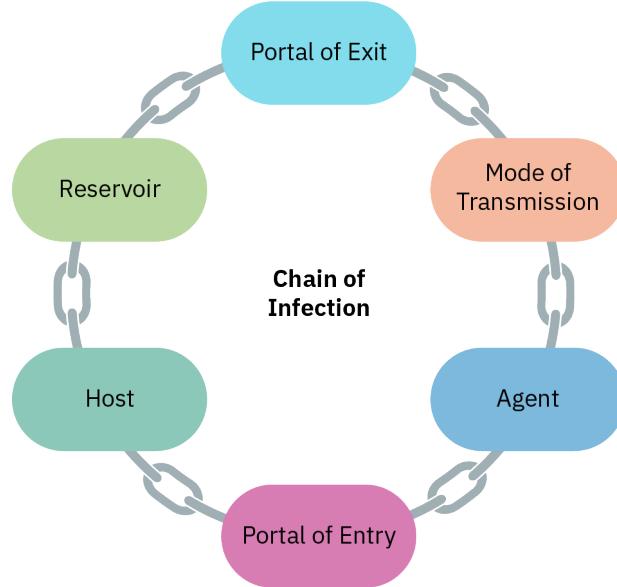

FIGURE 12.5 The components of the chain of infection are interlinked, similar to the epidemiological triad but with the added inclusion of transmission modes. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Reservoir

The **reservoir** is where the causal agent normally lives and reproduces. Reservoirs include the environment, humans, and animals. Communicable diseases that are transmitted from person to person—for example, sexually transmitted infections (STIs), measles, mumps, and many respiratory pathogens—are considered to have human reservoirs (CDC, 2012). As discussed, human reservoirs may be symptomatic, asymptomatic, or chronic disease carriers. With animal reservoirs (when the disease is transmissible from animals to humans, referred to as zoonosis), humans become accidental hosts. Examples include plague (from rodents) and rabies (from bats, dogs, and other mammals). Many newly recognized infectious diseases in humans, including West Nile encephalitis, acquired immunodeficiency syndrome (AIDS), Ebola infection, and severe acute respiratory syndrome (SARS), are thought to have emerged from animal hosts (CDC, 2012). Soil, water, and plants are considered environmental reservoirs. Many fungal agents live in the soil, and Legionella bacteria, the cause of Legionnaires' disease, often live in water within evaporative condensers (CDC, 2012).

Portal of Exit

The **portal of exit** from the reservoir is how the agent leaves its home, which enables it to act as the mode of transmission. Respiratory viruses such as influenza or tuberculosis exit the respiratory tract where the pathogen resides within its host. In pregnant individuals, some bloodborne agents such as syphilis can cross the placenta and infect the baby. Another portal of exit for bloodborne agents can be via cuts or needle punctures in the skin as can occur with hepatitis B or C, or even via a blood-drinking mosquito, as occurs with malaria (CDC, 2012).

Mode of Transmission

Diseases can be transmitted directly or indirectly (CDC, 2012). See [Table 12.1](#) for more information.

Transmission Method	Description	Example
Airborne transmission	<p>Transmission occurs via infectious agents capable of remaining suspended in the air over long distances and long periods of time, in stark contrast to droplets that fall to the ground within a few feet. Airborne transmission is considered a form of indirect transmission since the agent can be suspended in air particles for long periods of time.</p>	<p>The measles virus remains suspended in the air for long periods of time and is capable of infecting susceptible hosts even after the person with measles has left the room.</p>
Direct transmission	<ul style="list-style-type: none"> • Transmission occurs when an infectious agent is transmitted by direct contact or droplet spread. This person-to-person direct contact can occur via skin contact, kissing, and sexual intercourse. Transmission may also occur from direct contact with soil that harbors infectious pathogens. • Droplet spread is considered direct transmission as infected material is transmitted by direct spray of relatively large, short-range aerosols of the pathogen over a few feet prior to the droplets falling to the ground. 	<ul style="list-style-type: none"> • Examples include infectious mononucleosis, which is transmitted through kissing and sharing saliva; chlamydia, which spreads from person to person via direct contact; and hookworm, which is transmitted by direct contact with contaminated soil. • Many illnesses such as influenza, pertussis, and meningococcal disease are spread when an infected host talks, sneezes, or coughs near a susceptible host who then breathes in these infected droplets.

TABLE 12.1 Methods of Transmission

Transmission Method	Description	Example
Indirect transmission	<ul style="list-style-type: none"> • Transmission occurs when an infectious agent is transmitted via an inanimate object, also known as a vehicle or vector intermediary. • Vehicle-borne vectors that may indirectly transmit infectious agents include food, water, and inanimate objects such as bedding, countertops, or surgical equipment. A vehicle such as food or water can passively carry pathogens. • Diseases can also be transmitted indirectly from touching a contaminated surface such as a countertop and then touching the eyes, nose, or mouth. • Indirect transmission can also occur via vectors such as mosquitos or ticks. These vectors carry the infectious agent to a susceptible host. 	<ul style="list-style-type: none"> • Hepatitis A is a vehicle-borne vector disease; it can be passively carried in food or water, and once ingested, it transmits disease. • Lyme disease and malaria are examples of vector-borne diseases. • Lyme disease is transmitted by ticks, and malaria is transmitted by mosquitoes. • Influenza, norovirus, COVID-19, and conjunctivitis are all examples of diseases that can also be transmitted indirectly from touching a contaminated surface.

TABLE 12.1 Methods of Transmission

Portal of Entry

The **portal of entry** is how the agent infects a susceptible host. The portal of entry must provide contact with tissues that will allow it to reproduce or allow the toxin of the agent to act (CDC, 2012). Many infectious agents use the same portal to enter a host that they used to exit the source; for example, pertussis (whooping cough) exits the respiratory tract of the original host and enters the respiratory tract of the new host. The portal of exit and portal of entry can be the same, as in the case of malaria via a mosquito bite. Some infectious pathogens exit the source host in feces and are carried via unwashed hands to a vehicle-borne vector, such as food, to enter the new host through the mouth. This is known as the fecal-oral route (CDC, 2012). The skin, mucous membranes, and blood are other portals of entry (CDC, 2012).

Host

A susceptible host is a key component and final link in the chain of infection. Host susceptibility depends on a multitude of genetic, nonspecific, and lifestyle factors. Genetic factors of age, gender, physical health, and immune status; nonspecific factors such as skin integrity, gastric acidity, and respiratory tract anatomy; and lifestyle factors such as malnutrition, chronic disease, and alcoholism (CDC, 2012) all contribute to a host's susceptibility. An example of a genetic makeup that decreases a host's susceptibility is the sickle cell trait. Individuals with this genetic alteration are partially protected against certain types of malaria. Immunity refers to either prior immunization or prior exposure to a pathogen affording protective antibodies. By interrupting and stopping the chain of causation at any of the links, disease can be prevented.

Web of Causation

By the mid-20th century, antibiotics and vaccines to prevent or treat infections shifted public health attention away from infectious diseases to noninfectious diseases like cancer and diabetes. In the 1960s, the web of causation

became an epidemiological model to demonstrate the concept of multiple causation in the health and illness spectrum (Ventrilio et al., 2016). This model helps describe the multiple factors that underlie many chronic illnesses, giving each causative factor equal prominence in identifying determinants of disease. The emergence of the web of causation represented a shift in thinking about disease and suggested that the combination of multiple factors was the determining influence in the development of poor outcomes (Ventrilio et al., 2016). Epidemiologists today continue to make associations among lifestyle choices, behaviors, the environment, and even the social determinants of health and their relationship to health outcomes.

12.4 Types of Study Design

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.4.1 Describe the differences between descriptive and analytic epidemiology.
- 12.4.2 Discuss the purpose of experimental studies.
- 12.4.3 Describe the purpose of observational studies.
- 12.4.4 Discuss the different types of observational studies.
- 12.4.5 Describe how epidemiologists interpret epidemiological studies.

Epidemiology has two main branches: descriptive and analytical. **Descriptive epidemiology** considers person, place, and time of health events and seeks to describe disease variables (CDC, 2012). **Analytic epidemiology** searches for the why and how of diseases or other public health issues by testing hypotheses about causal relationships (CDC, 2012). **Causality** is the relationship between a cause and its effect. Data from descriptive studies suggest hypotheses that analytic epidemiologists test by assessing for causation patterns.

Descriptive epidemiology depicts the occurrence of health events within a population, focusing on the frequency and pattern of these events by examining the characteristics of person, place, and time in relation to each event (CDC, 2012). Descriptive epidemiology evaluates all the conditions surrounding a person who is affected by a health event and may look at factors such as age, education, health care access, race, gender, and socioeconomic position concerning that health event (CDC, 2012). When the people and places affected and the timing of an event are described, patterns may emerge that can be considered potential risk factors for similar events.

Analytic epidemiology searches for causes and effects of diseases or other health events, asking *why* and *how*, attempting to quantify a relationship between two variables (CDC, 2012). Since it focuses on the quality and the amount of influence that determinants have on the occurrence of diseases or other health events, analytic epidemiology requires a comparison, or control, group (CDC, 2012). Epidemiologists use analytic epidemiology to measure associations between exposures or risk factors and outcomes and to test hypotheses regarding causal relationships. The results of analytic epidemiology provide the evidence necessary to recommend appropriate prevention and control measures. The goal of analytic epidemiology is to reduce the incidence of health events or diseases by understanding their risk factors.

Types of Epidemiological Studies

The purpose of analytic epidemiologic studies is to identify and quantify the relationship between an exposure to a variable and a health outcome. Such studies require using two groups because one serves as the control or comparison group. Analytic epidemiologic studies fall into two broad categories: experimental and observational.

EPIDEMIOLOGICAL STUDIES: A BEGINNER'S GUIDE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/12-4-types-of-study-design>\)](https://openstax.org/books/population-health/pages/12-4-types-of-study-design)

This video provides an overview of the many types of widely used epidemiological studies, including interventional studies, cohort studies, case-control studies, and cross-sectional studies, described in this chapter. The video also discusses ecological studies, case series studies, and systematic reviews that are beyond the scope of this chapter.

Watch the video, and then respond to the following questions.

1. If you had to come up with a topic for an epidemiologic study question, what would it be? Why?

2. The video notes that all studies must be done in an “ethical way.” What do you think this means?
3. What are some advantages of a case-control study?

Experimental Studies

Experimental studies, also known as interventional studies, are considered the gold standard for a study when they are randomized and conducted under rigorous conditions. In experimental studies, the investigator controls or changes the factors thought to cause the health event under investigation and then observes what happens to the health state. These studies are conducted under carefully controlled conditions. An example is a clinical trial of a new vaccine. The investigator randomly assigns some participants to the placebo group (control group, those who do not receive the new vaccine) and others to the group that will receive the new vaccine (experimental group). The investigator then tracks all the participants over time to observe which participants get the disease that the new vaccine is intended to prevent. The researcher then compares the two groups to see if the intervention group (experimental vaccine group) has a lower rate of disease ([Figure 12.6](#)) (CDC, 2012).

A community trial is an experimental study conducted at the community level where one community is assigned an intervention and another community serves as the control, non-intervention group. The two communities are compared to determine whether the intervention demonstrated a positive change.

FIGURE 12.6 Vaccines undergo experimental testing with randomized controlled trials. In this photo, researchers engage in vaccine development. (credit: “NMRC Continues Phase 1 Testing of Diarrhea Vaccine” by Michael Wilson/U.S. Navy/Flickr, Public Domain)

Observational Studies

Observational studies are based on investigator observations of exposure and disease status. It is unethical to knowingly expose individuals to potentially harmful agents, so observational studies are commonly used when investigators suspect an agent’s effects are harmful. John Snow’s cholera studies were observational. Cohort studies, case-control studies, and cross-sectional studies are the most common types of observational studies used in epidemiological research (CDC, 2012).

A **cohort study** is an observational study of a cohort, a group of individuals who all share a certain characteristic. For instance, a group of people who have all contracted Lyme disease is a cohort.

In some ways, a cohort study is similar to an experimental study. As in an experimental study, the investigator documents whether or not study participants were exposed to what is being studied. For example, investigators might recruit a cohort of participants who have been exposed to cigarette smoke and compare the cohort’s rate of disease with the rate of disease of a group that has not been exposed to cigarette smoke. The investigator would then track participants of both groups to see if they developed the disease of interest.

A cohort study differs from an experimental study, however, in that the investigator in a cohort study only observes participants whose exposure status is already known. The investigator does not actively determine the participants’

exposure status (for example, by deliberately exposing a study group to cigarette smoke). After a set period, the investigator in a cohort study compares the disease rate in the exposed group to that of the unexposed group. The unexposed group acts as the comparison group and serves as an estimate of the expected amount of disease in a community. If the disease rate is significantly different in the exposed group, then the said exposure is considered to be associated with the disease (CDC, 2012).

Cohort studies may be classified as prospective or retrospective. In a prospective cohort study, participants are enrolled as the study begins and are followed over time, whereas in a retrospective study, the participants' exposure and outcome have already occurred. Retrospective cohort studies are helpful in disease investigations of distinct groups, such as investigations into outbreaks of uncommon diseases in health care or residential facilities. A major drawback of cohort studies is the possibility of differences between the two groups being studied with regard to risk factors and other exposures outside of the agent of interest, whereas experimental studies avoid this problem with randomization of subjects.

THEORY IN ACTION

The Framingham Heart Study

[Access multimedia content \(<https://openstax.org/books/population-health/pages/12-4-types-of-study-design>\)](https://openstax.org/books/population-health/pages/12-4-types-of-study-design)

This short video highlights one of the largest and longest prospective cohort studies ever undertaken in the United States. In the video, study director Dr. Ramachandran discusses how it was not until this study that smoking cigarettes, hypertension, and hypercholesterolemia were implicated as risk factors for heart disease and stroke.

Watch the video, and then respond to the following questions.

1. Had you ever wondered how hypertension and hypercholesterolemia were identified as major risk factors for heart disease and stroke?
2. Why do you think this study employed a prospective cohort study design?
3. Why do you feel it is still beneficial today to have this study ongoing?

For further information on the Framingham Heart Study, see [Honoring Their Legacy: The Framingham Heart Study's Original Cohort \(<https://openstax.org/r/framinghamheartstudy>\)](https://openstax.org/r/framinghamheartstudy).

In a **case-control study**, investigators enroll a group of individuals with a disease and a control group of individuals without the disease and compare previous exposures between the groups. While cohort studies measure and compare the incidence of disease in exposed and unexposed groups, case-control studies compare the frequency of exposure in a group that already has the disease to a group without the disease. The rates of exposure in the cases and in the controls are compared. Similar to the cohort study, if the amount of exposure among the case group is significantly higher than the amount in the control group, then the disease or illness is thought to be associated with that exposure. In this study design, it is important to identify an appropriate control group that is comparable to the case group in most ways in order to provide a fair estimate of the baseline exposures in a given population (CDC, 2012). Case-control studies can often be completed in less time and with less expense than cohort studies and tend to work well in the study of uncommon diseases (Omair, 2016).

THEORY IN ACTION

Analytic Epidemiology in Action: Case-Control Study

This vignette is based on an example of a real-world scenario of a 2003 outbreak of hepatitis A in Pennsylvania. Public health epidemiologists had been asked to investigate a cluster of hepatitis A cases. Investigators found that almost all affected individuals had eaten at a specific restaurant before the onset of their illness. Discovering the location of the likely outbreak source helped refine the hypothesis, but investigators did not know which foods were contaminated. Instead of assessing only the foods consumed by the ill individuals, the investigators knew they needed to compare the foods consumed by the ill individuals to foods consumed by well individuals who had eaten at the same restaurant during the same time period, looking for significant differences in the

foods consumed by the two groups.

The investigation found that 94 percent of the affected individuals ate mild salsa compared with 39 percent in the control group. This narrowed the investigation, and ultimately the green onions in the salsa were found to be the source of infection. Shortly after, the FDA issued an advisory to the public about the risk of hepatitis A and green onions.

(See Centers for Disease Control and Prevention, 2003; Wheeler et al., 2005.)

In a **cross-sectional study**, investigators enroll sample individuals from a specified population and simultaneously measure each participant's exposure and disease outcome to get a snapshot of a specified population at a given time. Cross-sectional studies do not determine the long-term development or risk of a disease. In this study approach, the identified cases are considered prevalent cases (the proportion of people with a disease at a certain time) because investigators know only that the cases existed at the time of the study but do not know their duration or whether the exposure happened before the outcome. These types of studies are used to document the prevalence of health behaviors (prevalence of smoking), health states (prevalence of obesity), and health outcomes (chronic conditions like hypertension) in a community at a given time (CDC, 2012). These studies are an excellent tool for descriptive epidemiological purposes.

Interpretation of Epidemiological Studies

Epidemiologists seek to understand and discover whether a causal relationship exists between an agent or exposure and a disease. Therefore, the study's first question is whether an association exists between the agent or exposure and the disease. Using comparison, an association exists when the agent or exposure and disease occur together more frequently than the baseline occurrence. A causal relationship is one possible explanation for observed associations, but an association by itself does not equate to a causal relationship. The next section describes frequency measures, the mathematical means of expressing risk, and the strength of associations between exposure and disease.

Epidemiology often uses frequency measures such as ratios, proportions, and rates. Ratios and proportions describe the characteristics of populations, while proportions and rates quantify morbidity and mortality. Frequency measures permit inferences to suggest risk among different groups, detect groups at high risk, and develop hypotheses about why these groups might be at increased risk. With any epidemiologic study, comparison is the foundation for analysis, comparing the observed amount of disease in a population with the expected amount of disease. The comparisons are then further quantified using such measures of association as risk ratios, rate ratios, and odds ratios that provide evidence regarding causal relationships between exposures and disease. The next section will look at epidemiologic measures in more detail.

12.5 Epidemiologic Measures

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.5.1 Define significant terms related to disease occurrence in a population.
- 12.5.2 Discuss mathematical terms used in epidemiology.
- 12.5.3 Describe epidemiological measures used to define and quantify health problems in and across defined populations.
- 12.5.4 Identify analytic methods for calculating key measures of morbidity, mortality, and measures of association.
- 12.5.5 Describe possible sources of error in epidemiological studies.
- 12.5.6 Understand epidemiological criteria used to establish causal relationships.

Epidemiologists often categorize the amount of a disease present in a community as a specific level of disease: endemic, hyperendemic, sporadic, epidemic, outbreak, or pandemic. Public health officials use this information to assist in planning appropriate interventions. The **endemic** level is the continual and constant presence of a disease within a geographic area—the observed level in a defined area; it may also be referred to as the usual rate of disease at any given time or the baseline level.

Persistent high levels of disease in a defined area are characterized as **hyperendemic**. Diseases that occur occasionally at irregular intervals are considered **sporadic** or infrequent. When the level of disease in a defined area rises above the endemic levels—a sudden increase in the number of cases of a disease above what is normally expected—it is referred to as an **epidemic**. Both infectious and noninfectious diseases can become epidemics. An **outbreak** is an epidemic that affects a limited geographic area. A pandemic is a worldwide epidemic. See [Pandemics and Infectious Disease Outbreaks](#).

Common Epidemiological Measures

Using epidemiological measures is one way of knowing when there is an excess of what is expected (Celentano & Szklo, 2019). Common frequency measures in epidemiology are ratios, proportions, and rates.

Ratios

A **ratio** is a comparison of any two values, calculated by dividing one interval by the other. The numerator and denominator do not have to be related. After dividing the numerator by the denominator, the result is expressed as the result “to one” or “:1” See [Calculating Ratios](#) for more detail on the calculation.

Ratios can be used as a descriptive measure, such as describing the man-to-woman ratio of participants in a study. They can also be used in calculations for the occurrence of illness or death between two groups. **Death-to-case ratio** is used as a measure of illness severity because it refers to the number of deaths attributed to a disease during a specific period of time divided by the number of new cases during the same period. As an example, rabies has a death-to-case ratio of almost 1, meaning that almost everyone who develops it dies from it (CDC, 2012).

CALCULATING RATIOS

Recall that:

$$10^0 = 1$$

$$10^1 = 10$$

$$10^2 = 10 \times 10 = 100$$

$$10^3 = 10 \times 10 \times 10 = 1,000$$

Basic Calculation for Ratios:

$$(\text{Numerator} \div \text{Denominator}) \times 10^n$$

Calculating Ratios: Example 1

You are a research nurse reviewing the medical histories of the study participants. Given this study’s parameters, they are categorized as having hypertension or not having hypertension.

Men with hypertension: 305

Men without hypertension: 4,702

Based on the data, calculate the ratio of men without hypertension to men with hypertension. Since this will be a one-to-one ratio, you will use 10^0 .

$$\text{Ratio} = \frac{4,702}{305} \times 10^0 = 15.4:1 \text{ (15.4 men without hypertension to 1 with hypertension)}$$

Calculating Ratios: Example 2

Imagine you are the public health nurse for a county in a rural part of the United States. You have been tasked with calculating the ratio of county citizens to the number of health clinics in the county—in other words, how many county residents each health clinic must serve.

Number of health clinics: 8

County population: 9,000

$$\text{Ratio} = \frac{9,000}{8} \times 10^0 = 1,125:1 \text{ (Each clinic must serve 1,125 county citizens.)}$$

(See Centers for Disease Control and Prevention, 2012.)

Proportions

A **proportion** is a form of ratio where the numerator represents a subset of the denominator. An example is looking at the percentage of a population that is younger than 18 years. Proportions can be communicated as a decimal, fraction, or percentage. See [Calculating Proportions](#) for more details on the calculation. Proportions are often used as descriptive measures, such as the proportion of children in a community vaccinated against the flu or the proportion of individuals at a boarding school who developed illness (CDC, 2012). Proportions also describe the extent of disease attributable to a particular exposure. Proportionate mortality is the proportion of deaths in a defined population during a defined time period that are attributed to different causes. Each cause is communicated as a percentage of all deaths, where the sum of causes equals 100 percent (CDC, 2012). These proportions are not rates, as the denominator is all deaths.

CALCULATING PROPORTIONS

Basic Calculation for a Proportion

(Number of persons or events with a particular characteristic ÷ Total number of persons or events, with the numerator being a subset of this total number) $\times 10^n$

With proportions, 10^n is usually expressed with $n = 2$, or 100, and conveyed as a percentage.

Calculating a Proportion

Refer to [Calculating Ratios](#) and the study looking at hypertension.

Men with hypertension: 305

Men without hypertension: 4,702

Based on the data, calculate the proportion of men who had hypertension.

Numerator (305) plus Denominator (4,702) = Total number of men; $(305 + 4,702) = 5,007$

$$\text{Proportion of men who had hypertension} = \frac{305}{5,007} \times 10^2 = 6.09\%$$

(See Centers for Disease Control and Prevention, 2012.)

Rates

In epidemiology, a rate is a measure of how often an event occurs in a specified population over a defined period of time. Rates are useful for comparing disease frequency in different locations, at different times, or among different groups of individuals, often considered a measure of risk (CDC, 2012). Epidemiologists use rates to describe incidence, prevalence, case-fatality, and attack rates. It is important to note that attack rate, prevalence rate, and **case-fatality rate** are not considered “true” rates by some as they are not expressed in units of time, but these proportions provide valuable information in looking for patterns and using data for comparison (CDC, 2012).

Morbidity is another term for having a disease, illness, or medical condition and includes disease, injury, and disability. Measures of morbidity characterize the number of individuals in a population who become ill or are ill at a specified time. Commonly used measures of morbidity are **attack rate**, also known as incidence proportion, secondary attack rate, **incidence rate**, point prevalence, and period prevalence. See [Incidence Rate](#), [Prevalence Rate](#), [Attack Rate](#), and [Case-Fatality Rate](#) for more detailed definitions of these rates. The **mortality rate** measures the frequency of death in a defined population during a specific time interval. See [Mortality Rate](#) for more details on the various mortality rates often used.

INCIDENCE RATE

An incidence rate is a proportion in which the numerator is all new cases of a disease or health condition during a given period of time. The denominator is the population at risk during the same period. Incidence rates describe how quickly a disease or illness occurs in a specified population. Incidence rates of a health condition in a population are often expressed as the incidence rate per 100,000 population.

Example:

In 2020, 70,000 new cases of disease X were reported in the United States. The estimated midyear U.S. population was approximately 319,000,000. Calculate the incidence rate of disease X in the United States in 2020.

Numerator: 70,000 new cases of disease X

Denominator: 319,000,000 estimated midyear population

$$10^n = 10^5 = 100,000$$

$$\text{Incidence rate} = \left(\frac{70,000}{319,000,000} \right) \times 100,000$$

Incidence rate = 21.94 new cases of disease X per 100,000 population

(See Centers for Disease Control and Prevention, 2012.)

PREVALENCE RATE

A **prevalence rate** is the proportion of a population with a health condition at a certain point in time or over an interval of time. An example is how many individuals in a population have or have had influenza in the month of February. Unlike incidence, prevalence includes all cases of a particular disease, both new and pre-existing, in the population at the specified time. Incidence is limited to new cases only. Prevalence is often measured for chronic diseases as they have long durations and unclear onsets.

Calculating Prevalence of a Disease

Numerator: All new and pre-existing cases during an established time period

Denominator: Population during the same period

Multiply the result by 10^n . A value of 100 is most often used for 10^n ; therefore, $10^n = 10^2 = 100$.

Point prevalence refers to the prevalence measured at a specified point in time, the proportion of individuals with a disease on a specified date.

Period prevalence refers to prevalence measured over a span of time.

(See Centers for Disease Control and Prevention, 2012.)

ATTACK RATE (INCIDENCE PROPORTION)

The attack rate is the proportion of a population that develops an illness during an outbreak. Another term for an attack rate is **incidence proportion**, and it can be thought of as a measure of risk.

Calculating Attack Rate

In a food poisoning outbreak, 50 out of 150 individuals develop nausea, vomiting, and diarrhea (n/v/d) after attending a party where the 150 individuals all ate cheddar cheese. To measure the *food-specific attack rate*, the numerator is the number of individuals who ate a specific food and became ill divided by the total number of

individuals who ate that food.

Numerator: 50 individuals who ate the cheddar cheese and developed n/v/d

Denominator: 150 individuals who ate the cheddar cheese

Multiply the result by 10^n . A value of 100 is most often used for 10^n ; therefore, $10^n = 10^2 = 100$.

$$\text{Food-specific attack rate} = \left(\frac{50}{150} \right) \times 100 = 33.3\%$$

Calculating Incidence Proportion (also known as risk)

In a study of men with and without hypertension, 165 of the men with hypertension (out of a total of 305 men with hypertension) had died during the follow-up study 10 years later. Calculate the risk of death for these men.

Men with hypertension: 305

Numerator: 165 deaths among men with hypertension

Denominator: 305 men with hypertension

$$10^n = 10^2 = 100$$

$$\text{Incidence proportion (Risk)} = \left(\frac{165}{305} \right) \times 100 = 54.1\%$$

(See Centers for Disease Control and Prevention, 2012.)

CASE-FATALITY RATE

A case-fatality rate is the proportion of individuals with a disease who die from it. With this proportion, the numerator can only include deaths among individuals included in the denominator, but the time periods do not need to be the same. It is a measure of disease severity.

For example, a multistate outbreak of hepatitis A was traced to contaminated strawberries. There were 300 cases and two deaths as a result of the infection.

$$\text{Case-fatality rate} = \left(\frac{2}{300} \right) \times 100 = 0.67\%$$

(See Centers for Disease Control and Prevention, 2012.)

MORTALITY RATE

A mortality rate is the measure of death in a defined population during a specific time period.

Numerator = Deaths occurring during a specific time period

Denominator = Size of the population where deaths occurred

Multiply the result by 10^n . Values of 1,000 or 100,000 are often used for 10^n ; therefore, $10^n = 10^3$ or 10^5 .

Commonly Used Measures of Mortality:

Crude death rate is the mortality rate from all causes of death for a population.

Numerator: Total number of deaths during a given time interval

Denominator: Mid-interval population

$$10^n = 10^3 \text{ or } 10^5$$

For example, suppose that a total of 3,000,000 deaths occurred in 2020. The estimated population was

400,000,000 at the midpoint of 2020. Therefore, the crude mortality/crude death rate in 2020 was $\left(\frac{3,000,000}{400,000,000}\right) \times 100,000 = 750$, or 750 deaths per 100,000 population.

Cause-specific death rate is the mortality rate from a specific cause in a population.

Numerator: Number of deaths assigned to a specific cause during a given time interval

Denominator: Mid-interval population

$$10^n = 10^5$$

For example, in 2020, there were 91,799 drug overdose deaths in the United States (CDC, 2022b). The midyear population of 2020 was 333,287,557. Therefore, the cause-specific (drug overdose) mortality rate was 27.5 per 100,000 population.

Infant mortality rate

Numerator: Number of deaths among children < 1 year of age during a specified time period

Denominator: Number of live births during the same time period

$$10^n = 10^3$$

Maternal mortality rate

Numerator: Number of deaths assigned to pregnancy-related causes during a specified time period

Denominator: Number of live births during the same time period

$$10^n = 10^5$$

(See Centers for Disease Control and Prevention, 2012.)

Measures of Association

Epidemiologists seek to identify causal relationships between agents and disease by first assessing whether they are associated. An observed association between an exposure or an agent and a disease may indicate a causal relationship, but it may be a result of an error with the sampling method used (Green et al., 2011). Measures of association, such as relative risk (risk ratio), rate ratio, odds ratio, and attributable risk, assess the degree to which the risk of disease increases when exposed to an agent, thereby demonstrating the strength of an association—or, put another way, the strength of a causal relationship. Measures of association essentially compare disease occurrence among two groups—one being the primary interest group and the other being the comparison group—and serve as epidemiological criteria to establish causal relationships (CDC, 2012).

Relative Risk

Relative risk (RR), or **risk ratio**, compares the risk of a health event among one group with the risk among another group, the comparison group. RR is the ratio of the incidence proportion of the health event in exposed individuals (or the group of primary interest) to the incidence proportion in unexposed individuals (or the comparison group). RR of 1.0 indicates equal risk between the two groups. RR greater than 1 indicates an increased risk for the group in the numerator, the exposed group. RR less than 1 indicates a decreased risk for the exposed group, signaling the exposure may protect against the disease or health event occurrence. See [Relative Risk](#) for more information on the calculation of RR and an example.

RELATIVE RISK

Calculating Relative Risk (RR)

Numerator: Risk of disease or health event, the incidence proportion, in primary interest group

Denominator: Risk of disease or health event, the incidence proportion, in comparison group

Example

A researcher is studying 300 individuals exposed to a potential carcinogen and 500 individuals who were not exposed to this potential carcinogen. After a five-year follow-up, 125 of the exposed individuals are diagnosed with the disease, and 75 of the unexposed individuals are also diagnosed with the disease. The relative risk of contracting the disease is calculated by:

Incidence proportion of the primary interest group (exposed group) is $(\frac{125}{300}) = 0.42$

Incidence proportion of the comparison group (unexposed group) is $(\frac{75}{500}) = 0.15$

Therefore, the RR is $(\frac{0.42}{0.15}) = 2.8$. This RR of 2.8 suggests the risk of disease in the exposed group is 2.8 times as high as the risk of disease in the unexposed group.

Rate Ratio

A **rate ratio** compares the incidence rates or mortality rates of two groups. Similar to the risk ratio, the two groups are usually differentiated by exposure to a suspected causative agent and a comparison group or are differentiated by demographic factors such as gender or age. The rate for the primary interest group (exposure group) is divided by the rate for the comparison group. A rate ratio of 1.0 indicates equal risk between the two groups. A rate ratio greater than 1 indicates an increased risk for the group in the numerator, the exposed group. A rate ratio less than 1 indicates a decreased risk for the exposed group, signaling the exposure may protect against the disease or health event occurrence. See [Rate Ratio](#) for more information on the calculation of rate ratio and an example.

RATE RATIO

Calculating Rate Ratio

Numerator: Incidence rate (or mortality rate) in primary interest group (exposure group)

Denominator: Incidence rate (or mortality rate) in comparison group (non-exposed group)

Example

A public health nurse is investigating a perceived increase in flu-related deaths in January–March of 2022 in a large city compared to flu-related deaths the year prior in January–March 2021 in the same city. In 2021, there were 129 flu-related deaths among a midyear population of 500,000. In 2022, there were 310 flu-related deaths among a midyear population of 502,000. Calculate the rate ratio as follows:

Mortality rate of the primary interest group (2022 incidence rate) is $(\frac{310}{502,000}) \times 1,000 = 0.62$

Mortality rate of the comparison group (2021 incidence rate) is $(\frac{129}{500,000}) \times 1,000 = 0.26$

Therefore, the rate ratio is $(\frac{0.62}{0.26}) = 2.4$. This suggests the risk of disease in the primary interest group is 2.4 times as high as the risk of disease in the comparison group, suggesting that in 2022 there was a higher mortality rate due to flu than in the year prior.

Odds Ratio

The **odds ratio** (OR) is similar to the RR as it quantitatively expresses the association between an exposure and a disease or health outcome. The OR is most often used to estimate the RR in case-control studies when the disease being investigated is rare. It is the ratio of the odds of developing a disease when exposed to an agent to the odds of developing the disease when not exposed. Investigators can use the OR to estimate the RR since RRs cannot be calculated from a typical case-control study. See [Odds Ratio](#) for more information on the calculation of the odds ratio and an example.

ODDS RATIO

Calculating Odds Ratio in a Case-Control Study

Numerator: Odds a case was exposed

Denominator: Odds a control was exposed

$$\text{Odds ratio} = \frac{(a \times d)}{(b \times c)} \text{ where}$$

a = number of individuals exposed and with disease

b = number of individuals exposed but without disease

c = number of individuals unexposed but with disease

d = number of individuals unexposed and without disease

Example

	Cases with Disease	Controls with No Disease	Totals
Exposed	$a = 190$	$b = 2,000$	2,190
Not exposed	$c = 140$	$d = 10,000$	10,140
Total	330	12,000	12,330

TABLE 12.2

Calculate the OR as follows:

$$\frac{(190 \times 10,000)}{(2,000 \times 140)} = 6.79$$

Now, using the same data in the table, calculate the RR as follows:

$$\frac{\left(\frac{190}{2,190}\right)}{\left(\frac{140}{10,140}\right)} = 6.28$$

The OR and the RR are close as the OR provides a realistic estimation of the RR.

Attributable Risk

The **attributable risk** (AR) is an often-used measurement of risk, representing the amount of disease among exposed individuals attributed to the exposure. AR represents the maximum proportion of disease that can be attributed to the exposure and is the maximum proportion of disease that can possibly be prevented by eliminating the exposure (Green et al., 2011). AR can also be stated as the attributable proportion of risk, the proportion of the disease among exposed individuals that is associated with the exposure, and can be used as a measure of the public health impact of a causative factor. It assumes the incidence of disease in the unexposed group is the baseline and expected risk for that disease. It also assumes that if there is a difference between the incidence of disease in the two groups, the difference is due to the exposure. This is an appropriate tool to measure risk when a single risk factor or exposure is being considered but does not work well when there are multiple exposures to various agents. See [Attributable Risk](#) for more information on the calculation of attributable risk and an example.

ATTRIBUTABLE RISK

Calculating Attributable Risk (AR)

Numerator: (Incidence in the exposed) – (Incidence in the unexposed)

Denominator: Incidence in the exposed

Example

A researcher is studying 300 individuals exposed to a potential carcinogen and 500 individuals who were not exposed to this potential carcinogen. After a five-year follow-up, 125 of the exposed individuals are diagnosed with the disease and 75 of the unexposed individuals are also diagnosed with the disease.

The incidence of disease in the exposed group is 125 individuals out of 300 ($100 \times \frac{125}{300} = 41.7\%$) who contract the disease.

The incidence of disease in the unexposed group is 75 individuals out of 500 ($100 \times \frac{75}{500} = 15\%$) who contract the disease.

To calculate the AR:

$\frac{(41.67 - 15)}{41.67} = 0.64$ or 64 percent, meaning that the proportion of disease that is attributable to the exposure is 64 percent. *Attributable to* does not equate to *caused by*, as this calculation is addressing association, not inferring causation.

Sources of Error

While reviewing epidemiological studies, the nurse must assess the strength of associations demonstrated in the study. A source of error can be a positive association discovered between an exposure and a health event when there is no true association. Another potential source of error occurs when no association is found between an exposure and health event when there is an association. A study may also find an association, but the strength of the association is greater or less than the actual association. These types of errors may be a result of chance, bias, or confounding. The nurse has a duty to examine each study for the possibility of these types of errors, which are explained in the following sections.

Chance

Chance refers to a random error that may occur within any study. The larger the **sample size** (the higher the number of participants), the less likelihood of a random error, but a large sample size does not eliminate the risk of a random error (Green et al., 2011). To assess for random error, epidemiologists use **statistical significance** and confidence intervals to permit an assessment of the study's risk for random error (Green et al., 2011). Studies with statistically significant results are unlikely to be the result of random error. **Confidence intervals** provide the relative risk (or other risk measure) found in the study and an interval within which the risk would most likely fall if the study were repeated multiple times. If a 95 percent confidence interval is chosen, the range includes results expected 95 percent of the time if the samples for new studies were continually drawn from the same population.

A **p value** represents the probability that the observed association could be the result of random error (Green et al., 2011). A p value of 0.2 means there is a 20 percent chance the values found could have occurred by random error with no actual association present. Epidemiologists strive to minimize false positives by using p values that fall below a selected level—often 0.05—known as **alpha**, or the significance level, for the results of the study to be statistically significant (Green et al., 2011). The 0.05 alpha level means there is a 5 percent probability that the association found in the study would occur without an actual association, occurring by chance. The outcome will be deemed statistically significant if the observed alpha (p value) falls below the preselected significance level (Green et al., 2011). Note that the p value does not give the probability that the risk estimate in the study is correct; similarly, the confidence interval does not provide the range within which the true risk lies.

Bias

Bias, also referred to as a systematic error (tendency to underestimate or overestimate the value of a parameter), is another source of error in a study's outcome, arising in the design or conduct of the study, data collection, or data analysis (Green et al., 2011). Researchers attempt to minimize bias through strong data collection protocols and overall study design. Bias results in a non-random error in a study result. When present, it may invalidate the results.

The two common categories of bias are selection bias and information bias. Selection bias results from an

inappropriate method of selecting study participants, particularly the control group; the control group should be drawn from the same population as the participants with the health event or health exposure that is under study. Selection bias also occurs when participants decline to participate after agreeing to do so or when they drop out before study completion.

An example of selection bias occurred in a study looking at the effect of hormone replacement therapy (HRT) on coronary heart disease (CHD) in women. Several observational studies demonstrated a decrease in CHD in women using HRT. Later randomized controlled trials found the opposite effect—that HRT may increase the risk for CHD in this population. The difference in the findings was related to selection bias. Among the women in the observational studies, those taking HRT tended to be younger, more health conscious, and more physically active than those who were not using HRT. This resulted in a health-conscious bias as the observational studies represented the usual woman who initiated HRT (Catalogue of Bias Collaboration et al., 2017). Women who participated in the randomized control trials were older, more likely to be overweight or obese, and were using HRT for a much shorter duration than the women in the observational studies (Hodis & Mack, 2022).

Information bias results from a weakness in measuring the exposure or disease in the study group. In particular, in a case-control study, information bias is a consideration because the researcher depends on information from the past to determine exposure and disease and their relationship (Green et al., 2011). Research has demonstrated individuals with disease (cases) recall past exposure better than individuals without disease (control), creating a potential for recall bias. With case-control studies, researchers sometimes need to rely on interviews with surrogates when study subjects have died of the disease under investigation or are not well enough to be interviewed (Green et al., 2011). For example, in a case-control study looking at Alzheimer's-type dementia, determining past exposures between the case and control groups could lead to information bias. In the cases, clients with Alzheimer's-type dementia may have difficulty recalling past exposures compared to the control group, clients without Alzheimer's-type dementia. Due to this recall bias, the presence of potential exposures as risk factors may be underreported in the case group, resulting in the researchers miscalculating the importance of these potential risk factors in disease development.

Confounding

Confounding is another type of error that may result in an incorrect causation or conclusion. This occurs when another factor (the confounder) is mistakenly identified as the agent associated with the outcome (Green et al., 2011). Confounding occurs when a confounder is both a risk factor for the disease and a factor associated with the exposure being investigated. This may result in an incorrect conclusion about causation, since the misidentified agent is not the true causal factor (Green et al., 2011). Confounding can be more of an issue with observational studies because in observational studies the participants are not assigned randomly to the comparison groups. Randomization helps to ensure that exposures, outside of the one being investigated, are evenly distributed between groups. Other techniques to limit confounding occur in the design stage with appropriate and thoughtful methods for selecting participants. If factors of age, gender, or certain lifestyle habits are potential confounders in a study, the investigators can limit the impact by selecting controls that match cases (Green et al., 2011). An example of confounding occurred when researchers were trying to link cigarette smoking to lung cancer. There was an established association that cigarette smokers had higher lung cancer rates, but this could have been due to other exposures or lifestyle factors and not the cigarette smoking. An argument could be made that individuals who smoke cigarettes are more likely to live in areas of higher pollution and that the pollution is causing the cancer. The confounding variable here is air pollution.

Establishing Causation

Causation refers to an increase in disease incidence among exposed subjects that would not have occurred if these subjects had not been exposed. Epidemiology cannot prove causation, but causation can be inferred from the data that epidemiologists and public health professionals analyze and interpret. In assessing causation, epidemiologists look for alternative explanations for the association, such as chance, bias, or confounding as mentioned previously. After this process has ruled out these sources of error, epidemiologists use the following nine factors—the Bradford Hill criteria, commonly referred to as Hill's criteria for causation—to guide them in making judgments about causation ([Table 12.3](#)).

1	Temporal relationship	The exposure (causal factor) must occur prior to disease development.
2	Strength of the association	The stronger the association (the higher the relative risk), the more likely the relationship is causal.
3	Dose-response relationship	The greater the exposure to the causal factor, the higher the risk of disease.
4	Replication of the findings	If the relationship is causal, the study results will have been replicated in different populations with consistent study results.
5	Biological plausibility (coherence with existing knowledge)	The causal relationship should be consistent with current biologic information.
6	Consideration of alternative explanations	The causal relationship is reinforced when bias and confounding have been ruled out and other possible explanations have been considered.
7	Cessation of exposure	If a causal factor results in disease, the risk of the disease is decreased when the causal factor is removed.
8	Specificity of the association	The causal factor or exposure is associated with one disease.
9	Consistency with other knowledge	If the relationship is causal, the findings would fit and be consistent with other information and data.

TABLE 12.3 Hill Criteria for Causation (See Green et al., 2011.)

12.6 Communicating Inferences from Epidemiologic Data

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.6.1 Discuss real-world applications of epidemiologic data in public health nursing.
- 12.6.2 Describe strategies to communicate epidemiological information to improve the population's health.

Nurses from all fields use epidemiologic data to inform client care. This can range from health promotion education on the heart health benefits of exercise, to a nutritious diet to support healthy bone growth, to smoking cessation to prevent lung cancer, to avoiding addiction by using the least amount of pain medication needed. The fields of nursing touched upon include acute bedside nursing, rehabilitation nursing, emergency nursing, nursing research, school nursing, corrections nursing, occupational health nursing, and community and public health nursing.

Application of Epidemiologic Data in Public Health Nursing

Epidemiologic research can assist in the identification of problems within a community or population and can assist in discovering the etiology of the problem or risk factors for the development of the issue. Epidemiologic health research can be descriptive or analytical and guide nurses and other public health professionals on a path of evidence-based interventions and recommendations to address the issue.

Community health nurses use health research from epidemiology as the foundation of evidence-based nursing practice and to inform and educate the public. A great example is Racial and Ethnic Approaches to Community Health ([REACH \(<https://openstax.org/r/reach>\)](https://openstax.org/r/reach)), a program administered by the CDC to reduce racial and ethnic health disparities. This program provides grant money to local health departments, communities, and related agencies to establish local and culturally appropriate programs that address various health issues among Black, Indigenous, and people of color (BIPOC) communities (CDC, 2022c). One such program is the fruit and vegetable prescription program in the Navajo Nation. A Community Outreach and Patient Empowerment (COPE) group in New Mexico created a fruit and vegetable prescription program (FVRx) to promote healthy eating (Society for Public Health Education, 2020). Clinic providers and community health workers identified eligible families and asked them to participate. The organizers collaborated with local stores so that these families received monthly vouchers to purchase fruits and vegetables. These families also met with community health workers to learn more about healthy eating and its impact on the incidence of obesity, heart disease, and diabetes. The FVRx led to community-level changes with improved access to nutritious food (Society for Public Health Education, 2020).

As the Agency for Healthcare Research and Quality (AHRQ) (2019) notes, research translation refers to the practice of taking scientific research and evidence and applying it to a practical setting. This is a vital aspect of a nurse's role as health promoter, educator, and advocate. Population and public health professionals can translate research into a usable tool to help prevent or address health events and diseases. For the underlying research to be trusted and used appropriately, public health professionals must learn to communicate the scientific findings in an easy-to-understand yet hard-to-forget manner. Technical terms must be put into simple language before they are disseminated. Communication techniques include tailoring the message, targeting the message to groups, using storytelling, and framing the message in a hard-to-forget manner (AHRQ, 2019).

Dissemination is the distribution of information to a particular audience to spread knowledge about a disease and its associated interventions. Dissemination can occur through different channels, settings, and contexts to increase the reach of the evidence and increase the motivation and ability to apply it (AHRQ, 2019). Using history as a guide, Semmelweis would have been more effective in his quest to save lives via handwashing had he clearly presented his supporting evidence and communicated the need for intervention based on it. If he had been able to garner professional and political support and articulate the case for why or how his intervention was feasible and cost-effective, the lives of many more women in labor could have been saved (Celentano & Szklo, 2019).

Communicating Epidemiological Information

Nurses play a large role in communicating important health-related epidemiological information to individuals, communities, and government departments. Before implementing a health promotion program, nurses must be sure they understand the underlying research and have reviewed the studies for quality and rigor. They can then tailor their message to the target population. The goal is to effectively educate individuals and community members on health-promoting behaviors such as lifestyle changes, appropriate health screenings, and vaccines. Having a strong foundation in epidemiologic research makes the information the nurse presents more persuasive and trustworthy. Recent examples include vaccine campaigns for COVID-19 and campaigns educating the public on the new guidelines for colon cancer screening.

Outbreak communication requires a different approach. Before communicating with the public during an outbreak, it is key for the nurse to think about how risk perception may influence the community (Trumpey et al, 2018). Many individuals view public health recommendations as just that: recommendations—suggestions for actions they do not necessarily need to follow. That is, they view advice through their own risk-benefit lens. It is important for nurses to consider factors influencing risk perception when working with communities during an outbreak or other public health crisis. See [Table 12.4](#) for factors influencing risk perception (Trumpey et al, 2018).

Acceptable Risks Are Perceived as	Less Acceptable Risk Is Perceived as
Being voluntary	Being imposed
Being under an individual's control	Being controlled by others
Having clear benefits	Having vague or delayed benefits
Naturally occurring	Human-made
Generated by a trusted source	Generated by an untrusted source
Being familiar	Being new
Affecting adults	Affecting children

TABLE 12.4 Factors Influencing Risk Perception

During an outbreak, trust and credibility of the individual delivering any communication significantly influences the communication's ability to persuade others to follow public health recommendations. Risk communication literature has recognized several factors associated with coming across as trustworthy and credible. They are empathy and caring, honesty and openness, dedication and commitment, and competence and expertise (Trumpey et al., 2018).

During an outbreak, public health professionals must effectively engage the community with information and guidance to promote disease control and prevention efforts. At the beginning, there are a lot of unknowns, and it can be difficult to communicate effectively. It is crucial to determine and define the roles and responsibilities of individuals involved in the outbreak response (Trumpey et al., 2018). For a public health nurse, this may include interfacing with the community, or it may be more behind-the-scenes. Either way, determining one's role is the first

step. After role delineation, the nurse must be able to identify the target audience and tailor health-related recommendations to that population.

12.7 The Role of Epidemiology in Scientific Decision-Making and Policy Development

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 12.7.1 Discuss the role of epidemiology in scientific decision-making.
- 12.7.2 Describe the role of epidemiology in policy development.
- 12.7.3 Describe how epidemiology supports the 10 essential public health services.

As the pioneers of epidemiology have demonstrated, when rigorously conducted, reported, and communicated, epidemiological studies can result in major health policy changes. Edward Jenner demonstrated that vaccination effectively protects the public from infectious diseases (Riedel, 2005). He operated purely on observational data and then used his observations to experiment with a “volunteer.” There are many current ethical issues with how Jenner demonstrated the efficacy of vaccination against smallpox, but at the time, he followed the causal relationships he observed (Celentano & Szklo, 2019). Ignaz Semmelweis used data and astute observations to link childbed fever to dirty hands. He used his knowledge to implement a basic intervention that saved many childbearing individuals’ lives. Unfortunately, he did not disseminate his findings widely or communicate them effectively, and this caused a significant delay in handwashing policy adoption (CDC, 2012; Mawdsley, 2022).

There is a need to clearly present supporting scientific evidence for a proposed intervention to gain public acceptance of evidence-based prevention policies. This involves gathering professional and political support (CDC, 2012). John Snow was able to use his observations and gather hard data by knocking on people’s doors in cholera-affected areas. He documented his findings and then correlated them on visual platforms such as the spot map (CDC, 2012; Celentano & Szklo, 2019; Wills, 2018). He could use his data and rigorous study design to write reports and communicate them to local authorities. Ultimately, he was able to direct public health action on water safety (CDC, 2012). Florence Nightingale also used statistics and data to document and report on unnecessary deaths within the military. She created graphs and other visual representations to demonstrate how simple sanitary interventions could save lives. She gained the support of politicians and other influential people and was able to bring about public health reforms (Andrews, 2022; Gershon, 2020).

Epidemiology: The Foundation of Scientific Decision-Making

Epidemiology is at the foundation of scientific decision-making in health care and public health. Recall that epidemiology is the scientific study of the distribution and determinants of diseases and health outcomes in populations. Epidemiology aims to develop methods of controlling health problems, limit the consequences of illness, and maximize health. It is a broad definition with major implications for scientific decision-making. Health care clients, professionals, and public health practitioners, including nurses, base their health care decision-making and health education on sound epidemiological studies. These studies form the basis for the education that health care professionals provide at all levels. For example, epidemiological studies have demonstrated an association between screening for certain diseases and overall decreased morbidity and mortality. Other epidemiological studies have shown that decreased saturated fat intake and increased exercise are associated with better cardiovascular health.

The U.S. Preventive Services Task Force

The U.S. Preventive Services Task Force ([USPSTF \(https://openstax.org/r/uspstf\)](https://openstax.org/r/uspstf)) is an independent organization of national experts in disease prevention and evidence-based medicine. The goal of the USPSTF is to improve the nation's health by making evidence-based recommendations about clinical preventive services (USPSTF, n.d.). The evidence that the task force reviews for scientific decision-making comes from epidemiological studies that are rigorously reviewed by the task force members. The task force assigns a letter grade (A, B, C, or D) or an insufficient statement based on the strength of the evidence and the balance with the benefits and harms of the preventive service in question, focusing on the primary care setting and the services that are referred by the primary care provider. Each year the task force reports to Congress on evidence gaps in research on clinical preventive services and recommends priority areas that should be further evaluated.

U.S. PREVENTIVE SERVICES TASK FORCE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/12-7-the-role-of-epidemiology-in-scientific-decision-making-and-policy-development>\)](https://openstax.org/books/population-health/pages/12-7-the-role-of-epidemiology-in-scientific-decision-making-and-policy-development)

This two-minute video provides an overview of the USPSTF, explaining its purpose and the benefits of its recommendations to primary care clinicians and their clients.

Watch the video, and then respond to the following questions.

1. How does the USPSTF make recommendations about ways to prevent disease?
2. In what ways does the work of USPSTF improve population health?

The Agency for Healthcare Research and Quality

The [AHRQ \(<https://openstax.org/r/nhqrdr>\)](https://openstax.org/r/nhqrdr) is another organization that uses epidemiological studies as a foundation for clinical practice guidelines. AHRQ is an official government organization under the Department of Health and Human Services (HHS) with a mission to produce evidence to ensure health care quality; make health care safer, more accessible, equitable, and affordable; and work with the HHS and other governmental partners to ensure that clinical health care evidence is understood and used appropriately (AHRQ, 2023b). AHRQ provides a great example of the role of epidemiology in scientific decision-making through its evidence-based practice center (EPC) that produces reports providing comprehensive, science-based information on common, costly medical conditions and new health care technologies and strategies to combat them (AHRQ, 2023a). These EPC reports are used for informing and developing quality measures, coverage decisions, educational materials, clinical practice guidelines, and research agendas (AHRQ, 2023a).

The Framingham Heart Study

An example of epidemiology's role in scientific decision-making is the Framingham Heart Study (FHS). As mentioned, the FHS is the longest-running prospective cohort study in the United States and one of the largest; it has had over 15,000 participants over the past 70 plus years (Andersson et al., 2021; Soto, 2018). Founded in 1948, the FHS initially was designed to look for common characteristics contributing to cardiovascular disease (CVD) as one out of every two deaths was caused by CVD in the 1940s (Soto, 2018). The study's findings—that smoking, high cholesterol, hypertension, and obesity are all common characteristics contributing to CVD and stroke risk—seem common knowledge to many in the health care field now, but they were unexpected when the study was first envisioned (Soto, 2018). From the FHS, many public health campaigns were initiated. Some are targeted to health care professionals, such as the Framingham Heart Score, which was used to calculate the risk of developing heart disease over a 10-year period (subsequently replaced by the American Heart Association and the American College of Cardiology Atherosclerotic cardiovascular disease calculator), and many are targeted to the public, such as campaigns to increase exercise and encourage a lower-fat diet. This cohort study demonstrates the power of epidemiology in scientific and health care decision-making.

Epidemiology: The Basis for Policy Development

Public health policy is based on evidence, and evidence can be garnered through well-designed epidemiological studies. Undergirding the development of policies that positively affect health outcomes of populations is one of the key roles of epidemiology.

Findings from epidemiological studies affect population health through a primary and secondary prevention lens and as a way to control disease. As mentioned, epidemiology is defined as the scientific study of the distribution and determinants of diseases and health outcomes in populations to increase understanding of disease and disease determinants to improve health outcomes. These are the intentional and practical applications of the study of epidemiology. They are investigations originated to address current and evolving health challenges with direct applications to public health through formulating and evaluating public policy. Developing public policy is, in fact, considered integral to the practice of epidemiology. John Snow's examination of the cholera outbreaks in London is a classic example of this direct application for public policy. His removal of the handle from the Broad Street pump demonstrates the policy implications of his research findings. He was able to clearly document his findings, build trusting relationships within the London community and with lawmakers, and effectively affect health policy.

A contemporary example of the role of epidemiology in policy development is the history of youth tobacco control in the United States, using epidemiology to drive change and create a positive difference in health outcomes. By the 1960s, smoking had been linked to poor health outcomes such as lung cancer and other respiratory diseases, and great strides throughout the 1970s through the 1980s resulted in a dramatic decrease in adult smoking habits but did not impact youth smoking rates (Aldrich et al., 2015). In 1994, to address this issue based on descriptive and analytic epidemiological studies, the Surgeon General's report recommended a paradigm shift in thinking about youth smoking. It shifted the focus from individuals, historically the target of youth smoking prevention programs, to populations and communities. This was accomplished through policy, and the American Stop Smoking Intervention Study for Cancer Prevention (ASSIST) exemplified this paradigm shift. The ASSIST program, with funding from the National Cancer Institute, many state health departments, and the American Cancer Society, changed economic, social, and cultural environmental factors in the states with participating health departments to discourage youth from smoking, motivated by epidemiologic evidence that secondhand smoke was dangerous (Aldrich et al., 2015). By reframing the issue as a societal concern over an individual problem, the community approach had a wider reach and could integrate tobacco-free norms into community institutions. ASSIST focused on four policy areas:

1. Elimination of tobacco smoke in public places
2. Decreased advertising and promotion of tobacco products
3. Decreased youth access to tobacco
4. Increased taxes on tobacco

By the time ASSIST ended in 1999, there were small but statistically significant reductions at the population level in smoking prevalence among adults compared with non-ASSIST states, and this decrease has continued. In 2021, 11.5 percent of adults (18 years and older) in the United States currently smoked cigarettes, a major decline from 20.9 percent of the population in 2005, a population health victory (CDC, 2023).

Intersection of Epidemiology and the 10 Essential Public Health Services

As introduced in [Foundations of Public/Community Health](#), the 10 Essential Public Health Services (EPHS) are the public health activities necessary to ensure healthy communities. This framework was developed under the auspices of the CDC and the National Institutes of Health (NIH). Originally released in 1994, it was updated in 2020 to better align with contemporary community and public health practice. The goal of the EPHS is to achieve equity by promoting policies, systems, and community conditions that facilitate optimal health for everyone. This is accomplished by removing systemic and structural barriers that have resulted in health inequities (CDC, 2022a).

Epidemiology supports the 10 Essential Public Health Services in the following ways (CDC, 2022a):

Investigation and Monitoring

1. Assesses and monitors population health status (factors that influence health as well as community needs and assets) by
 - using vital statistics to track population changes in natality and mortality, and
 - using disease statistics to trend rates of communicable and noncommunicable diseases in the community.
2. Investigates, diagnoses, and addresses health problems and hazards affecting the population by
 - providing population health data to track diseases,
 - investigating unusual disease activity, and
 - launching epidemiologic investigations.

Policy Development

3. Communicates effectively to inform and educate people about health, factors that influence it, and how to improve it by
 - developing and distributing appropriate health information and resources,
 - using a variety of communication methods including social media, mass media, and peer networks,
 - developing and using culturally and linguistically appropriate information, and
 - engaging in two-way communication to build trust.
4. Strengthens, supports, and mobilizes communities and partnerships to improve health by

- facilitating partnerships in the community that affect health,
 - building relationships with diverse groups within a community that reflect the population, and
 - supporting existing community partnerships with public health expertise.
5. Creates, champions, and implements policies, plans, and laws that impact health by
 - developing policies that improve public health and strengthen communities,
 - developing and implementing health improvement strategies,
 - providing input into policies and laws to ensure that health impact is reflected,
 - examining and improving existing policies and laws to correct past wrongs, and
 - ensuring that policies and laws are equitable for all to achieve health.
 6. Uses legal and regulatory actions designed to improve and protect the public's health by
 - ensuring that laws are equitably implemented,
 - conducting enforcement of sanitation with food preparation, safe drinking water, and hazardous exposures,
 - monitoring the quality of health care-related services, and
 - licensing of the health care workforce.

Assurance

7. Ensures an effective system with equitable access to the individual services and care needed to be healthy by
 - connecting populations to needed services,
 - ensuring access to cost-effective and quality health and social services,
 - sharing data across partnerships to foster health and well-being, and
 - contributing to the development of a safe and competent health care workforce.
8. Builds and supports a diverse and skilled public health workforce by
 - providing education and training,
 - building partnerships with schools and training programs,
 - promoting a culture of learning in public health, and
 - incorporating public health principles in non-public health curricula.
9. Improves and innovates public health functions through ongoing evaluation, research, and continuous quality improvement by
 - linking public health research with practice,
 - using research to inform decision-making, and
 - contributing to the base of evidence in public health.
10. Builds and maintains a strong organizational infrastructure for public health by
 - ensuring that resources are allocated equitably,
 - exhibiting ethical and effective decision-making, and
 - being accountable and inclusive with all community partners.

CASE REFLECTION

Epidemiological Information and the 10 Essential Public Health Services

Read the scenario, and then respond to the questions that follow.

Pedro is a public health nurse who works for a city health department. One afternoon, he receives a call from Suri, a college student who will be spending a semester in Cambodia. Suri has heard that dengue is a health risk in tropical and subtropical climates. She would like more information from the health department as she prepares for her trip.

After reviewing the CDC website for the most up-to-date information on dengue, Pedro explains that it is an infectious disease transmitted by the bite of an infected Aedes mosquito. The mosquito becomes infected with dengue virus when it bites a person—or in some locations, a monkey—who has dengue. Suri interrupts to ask if she could catch dengue directly from an infected person since dengue is an infectious disease, and Pedro says no,

dengue cannot be spread directly from person to person. Pedro explains that one in four people who are infected with dengue will become sick and that symptoms range from mild to severe, but severe dengue can be life-threatening within a few hours. Suri tells Pedro that she'll be living in Phnom Penh and spending lots of time indoors, so she assumes living in a city will reduce her risk of infection. Pedro explains that dengue rates actually tend to be higher in urban areas with higher concentrations of people. Living in a high-risk area like Cambodia where the disease is endemic increases Suri's chances of infection. Pedro advises Suri to protect herself by wearing long-sleeved shirts and pants, using an approved insect repellent, sleeping under a mosquito net, and avoiding locations where mosquitoes tend to thrive, such as near standing water. He also directs her to the [CDC website](https://openstax.org/r/dengue) (<https://openstax.org/r/dengue>) for more information.

1. What causes dengue?
 2. Utilizing the chain of infection, describe the process of infection with dengue.
 3. How can Suri protect herself from mosquito bites while abroad?
 4. What 10 Essential Public Health Services is Pedro utilizing when working with Suri?
-

This chapter has highlighted the important role epidemiology plays in public health, particularly in disease control and prevention. Epidemiology is the scientific underpinning of all public health efforts, from prevention of disease, illness, accidents, and injuries to early identification of chronic diseases via screening to management of disease outbreaks and complications from disease. The mission of public health is to ensure the conditions in which people can be healthy, and epidemiology provides the evidence for scientific decision-making and education efforts to fulfill that mission. Nurses must have a basic understanding of epidemiological principles to speak knowledgeably about the evidence underlying recommended public health interventions. Community and public health nurses fulfill the mission of public health by participating in the 10 Essential Public Health Services within the community and population in which they serve.

Chapter Summary

12.1 Epidemiology Defined

Epidemiology is the scientific study of the distribution and determinants of diseases and health outcomes to improve the health and safety of populations by establishing causal factors for health issues. Epidemiological objectives include identifying the cause of disease or factors that increase an individual's risk for disease, identifying how diseases are transmitted, determining the extent of disease in a community, evaluating preventive and therapeutic measures of health care delivery, and providing the foundation for developing public policy regarding disease prevention and health promotion. By identifying causes and risk factors of disease development, public health nurses can intervene early to reduce morbidity and mortality from the disease. Epidemiology provides the opportunity to develop an evidence-based foundation for prevention programs.

12.2 Historical Perspective

Epidemiology has been traced back to Greek physician Hippocrates circa 400 BCE. Since then, epidemiologists Edward Jenner, Ignaz Semmelweis, John Snow, and Florence Nightingale, among others, helped to shape epidemiology into the science and the action of public health. They used their observation skills and disseminated their findings widely to gain support from politicians and other government officials and to promote the health and well-being of the public.

12.3 Epidemiological Approaches

The epidemiologic triad describes disease as a result of the relationship among a susceptible host, an external agent, and an environment that brings the host and agent together. The chain of infection is an epidemiological model that depicts the complex, nuanced interplay between the host, agent, and environment and includes a reservoir, portal of exit, mode of transmission, agent, portal of entry, and host. The natural history of disease follows diseases through stages: susceptibility in a host, subclinical disease where disease carriers become a concern, and clinical disease in which overt symptoms are present. Understanding these epidemiological approaches enables nurses to direct the most appropriate public health intervention at any link in the chain of infection.

12.4 Types of Study Design

Descriptive epidemiology covers the time, place, and person of epidemiologic events and seeks to describe disease variables. Analytic epidemiology searches for

the why and how of diseases or other public health issues by testing hypotheses about causal relationships. In experimental studies, the investigator determines the exposure for the participants. In observational studies, participants are exposed under natural conditions. Cohort studies, case-control studies, and cross-sectional studies are the most common types of observational studies used in epidemiological research.

12.5 Epidemiologic Measures

Ratios can be used as a descriptive measure or to calculate the occurrence of illness or death between two groups. Proportions are often used to describe the extent of disease attributable to a particular exposure. A rate measures the frequency of an event's occurrence in a specified population over a defined period. Epidemiologists use rates to describe incidence, prevalence, case-fatality, and attack rates. Measures of morbidity characterize how many individuals in a population become or are ill at a specified time. Mortality rate measures the frequency of death in a defined population during a specific interval. Measures of association assess the degree to which the risk of disease increases when exposed to an agent, thereby demonstrating the strength of a causal relationship.

12.6 Communicating Inferences from Epidemiologic Data

Research translation applies scientific research and evidence to a practical setting. Population and public health nurses can translate epidemiological research into a tool to help prevent or address health events and diseases. Dissemination is the distribution of information to a particular audience to spread knowledge about a disease and its associated interventions.

12.7 The Role of Epidemiology in Scientific Decision-Making and Policy Development

Epidemiologic research can help identify problems in a community or population, assist in discovering the etiology of a problem or risk factors for its development, and guide nurses and other public health professionals toward evidence-based interventions and recommendations to address the issue. When rigorously conducted, reported, and communicated, epidemiological studies can result in major health policy changes. Findings from epidemiological studies affect population health from a primary and secondary

prevention lens and as a way to control disease.

Key Terms

agent something physical, chemical, nutritional, psychosocial, or biologic that can cause a health issue; must be present for a disease to occur

airborne transmission occurs when infectious agents are capable of remaining suspended in air over long distances and long periods of time, in contrast to droplets that fall to the ground within a few feet

alpha the *p* value or the significance level for the results of a study to be deemed statistically significant

analytic epidemiology the study of the causes and effects of diseases or other health events, looking for the *why* and the *how*, attempting to quantify a relationship between two variables

attack rate the proportion of a population that develops an illness during an outbreak (synonym of *incidence proportion*)

attributable risk (AR) a measurement of the amount of disease among exposed individuals that is attributed to the exposure

bias a systematic error that underestimates or overestimates the value of a parameter; a source of error in a study's outcome arising in the design or conduct of the study, data collection, or data analysis

carriers individuals with incubating disease or preclinical infection but without overt symptoms who are still capable of transmitting disease

case-control study a study design in which investigators enroll a group of individuals with a disease and a group of individuals without the disease and compare previous exposures between the groups

case-fatality rate the proportion of individuals with a disease who die from it

causality the relationship between cause and effect

chain of infection an epidemiological model that allows for a complex and nuanced interplay between the host, agent, and environment of the epidemiological triad

chance a random error in a study

clinical disease stage stage within the natural history of disease during which signs of the disease develop and diagnosis may occur

cohort study a study in which the investigator documents whether or not study participants were exposed to what is being studied

confidence intervals the relative risk (or other risk measure) found in the study and an interval within which the risk would most likely fall if the study

were repeated multiple times

confounding a type of error that may result in an incorrect causation or conclusion

cross-sectional study a study in which a sample of individuals from a specified population is enrolled and the exposure and disease outcome are measured simultaneously for each participant; provides a snapshot of any specified population at a given point in time

death-to-case ratio the number of deaths attributed to a disease during a specific period of time divided by the number of new cases of that disease during the same period

descriptive epidemiology the frequency and pattern of health events within a population according to the characteristics of person, place, and time

direct transmission transmission of an infectious agent from a reservoir to a host by direct contact or droplet spread of infected material

droplet spread infected material transmitted by direct spray of relatively large, short-range aerosols of the pathogen over a few feet prior to the droplets falling to the ground

endemic the continual and constant presence of a disease within a given geographic area

environmental factors in the epidemiologic triad, the biologic environment of plants, animals, and toxins, including vectors that carry infectious agents and the reservoirs where infectious agents are normally found

epidemic when the level of disease in a defined area rises above endemic levels

epidemiological triad a model of disease causation; classically describes disease as a result of the relationship between a susceptible host, an external agent, and an environment bringing the host and agent together

epidemiology scientific study of the distribution and determinants of diseases and health outcomes in populations

experimental studies in epidemiology, studies in which the investigator controls or changes the factors thought to cause a health event and then observes what happens to the health state

health events disease, injury, or death

host an individual, a family, a group of high-risk individuals, or a community within the context of the epidemiological triad

hyperendemic persistent high levels of disease in a defined area

incidence proportion the proportion of a population that develops an illness during an outbreak (synonym of attack rate)

incidence rate during a given time period, all new cases of a disease or health condition divided by the population at risk

indirect transmission transmission that occurs when an infectious agent is transmitted from a reservoir to a host by suspended air particles, inanimate objects also known as vehicles, or vector intermediaries

morbidity having a disease, illness, or medical condition; includes disease, injury, and disability

mortality rate the frequency of death in a defined population during a specific time interval

natural history of disease events that occur before development of a disease, during the course of the disease, and at the conclusion of the disease

observational studies epidemiological studies based on investigator observations of exposure and disease status

odds ratio (OR) odds a case was exposed divided by the odds a control was exposed; quantitatively expresses the association between an exposure and a disease or health outcome; most often used to estimate the relative risk in case-control studies when the disease being investigated is rare

outbreak an epidemic affecting a limited geographic area

p value the probability that an observed association could be the result of random error

pathogenicity the ability of an agent to cause disease, influencing disease onset

portal of entry how an agent infects a susceptible host

portal of exit how an agent leaves its home base in the chain of causation/infection

prevalence rate proportion of a population that has a health condition at a certain point in time or over a time interval

proportion a form of a ratio in which the numerator represents a subset of the denominator

rate ratio compares the incidence rates or mortality rates of two groups

ratio a comparison of any two values, calculated by dividing one interval by the other

relative risk (RR) the ratio of the incidence proportion of the health event in exposed individuals (or the group of primary interest) to the incidence proportion in unexposed individuals (or the comparison group); compares the risk of a health event among one group with the risk among another group; see also risk ratio

reservoir where the causal agent normally lives and reproduces in the chain of causation

risk ratio synonym of *relative risk*

sample size the number of participants in a study

sporadic diseases that occur at irregular intervals

spot map a type of epidemiological map that shows the geographic distribution of cases of illness or disease by marking each case with a dot on a map

statistical significance an assessment for random error in a study

subclinical disease stage the natural history of disease stage after exposure but prior to clinical disease in which individuals have pathologic change but no overt symptoms

susceptibility stage the initial interactions between the agent, host, and environment during the pre-pathogenesis period, during which time primary prevention measures could be implemented to prevent disease onset

Review Questions

1. Which of the following activities best defines epidemiology?
 - a. Prescribing prophylactic antibiotics for an individual suspected of having been exposed to anthrax
 - b. Teaching a community class to those newly diagnosed with diabetes
 - c. Recommending that a restaurant temporarily close for deep cleaning after implicating it as the source of a norovirus outbreak
 - d. Encouraging families in the community to eat dinner together every night

2. Which factors make up the epidemiological triad?
 - a. Agent, host, environment
 - b. Person, place, time
 - c. Source, mode of transmission, host
 - d. Portal of entry, agent, portal of exit

3. The school nurse is developing a plan to reduce direct transmission of disease. Which mode of transmission will be included in this plan?

- a. Droplet spread
 - b. Foodborne
 - c. Mosquito borne
 - d. Surface spread
4. Which description of disease activity in a single area corresponds to endemic levels of disease?
- a. There are usually 20–30 cases each week, and this past week there were 29 cases.
 - b. There are usually fewer than 20 cases per year, and this past week there were 2 cases.
 - c. There are usually up to 10 cases per week, and this past week there were 40 cases.
 - d. There are usually 100,000 cases worldwide each month, and this past month there were 10 million cases worldwide.
5. What type of study is the public health nurse using to collect exposure and lifestyle information to assess the relationship between these factors and consequent occurrence of disease?
- a. Experimental
 - b. Cross-sectional
 - c. Cohort
 - d. Case-control
6. What is the hallmark feature of an analytic study in epidemiology?
- a. Use of an appropriate comparison group
 - b. Randomization in recruiting study participants
 - c. Confirmation of diagnosis via lab testing
 - d. Testing a hypothesis
7. What type of study randomly assigns an individual to receive the currently available formulation of a blood pressure medication or the newly formulated slow-release formulation of the blood pressure medication?
- a. Experimental
 - b. Observational
 - c. Case-control
 - d. Cohort
8. Which action highlights Florence Nightingale's role as an epidemiologist?
- a. Dressing soldiers' infected wounds
 - b. Connecting poor sanitation with negative health outcomes
 - c. Developing training schools for nurses and midwives
 - d. Changing linens and frequently bathing clients
9. In which stage of disease progression would the nurse classify a client who has elevated blood pressure but no symptoms?
- a. Susceptibility stage
 - b. Subclinical stage
 - c. Clinical stage
 - d. Carrier stage
10. The public health nurse is studying the proportion of the population in a certain county that had pneumonia during the winter months. Which epidemiological measure will the nurse use?
- a. Attack rate
 - b. Incidence rate
 - c. Prevalence rate
 - d. Risk ratio

CHAPTER 13

Pandemics and Infectious Disease Outbreaks

FIGURE 13.1 Public health nurses prepare stretchers during the 1918 flu pandemic. (credit: modification of work “St. Louis Red Cross Motor Corps on duty Oct. 1918 Influenza epidemic” by American Red Cross/Library of Congress, No Known Restrictions)

CHAPTER OUTLINE

- 13.1 Pandemics Throughout History
 - 13.2 Types of Infectious Disease Outbreaks
 - 13.3 Infectious Disease Prevention and Control
-

INTRODUCTION Sally, a newly hired public health nurse with the board of health department, receives a call from a local pediatrician, Dr. Liu, who reports that in one day she has seen eight children with fever, abdominal cramping, vomiting, and diarrhea. While normally these symptoms would not cause much concern, seeing this many cases in one day is unusual. Dr. Liu mentions that each child has been swimming at the town pool, and Sally and Dr. Liu discuss the testing Dr. Liu has ordered for her clients.

Public health nurses like Sally play a critical role in managing infectious disease outbreaks, including pandemics like COVID-19. This chapter discusses pandemics throughout history that have served as a catalyst for public health disease surveillance and interventions. It describes the types of infectious disease outbreaks, highlighting common communicable diseases nurses encounter. Finally, the chapter examines infectious disease control and prevention, the steps in an outbreak investigation, public health surveillance, and vaccine-preventable diseases, highlighting the role of the nurse.

13.1 Pandemics Throughout History

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 13.1.1 Differentiate between pandemics, endemics, and epidemics.
- 13.1.2 Compare the major pandemics afflicting humanity over the past two centuries.
- 13.1.3 Discuss how the 1918 pandemic changed history.

Recall from [Epidemiology for Informing Population/Community Health Decisions](#) that endemic disease occurs when an infection or disease becomes common in a population or area. Examples include the annual flu strains, influenza A and B. An epidemic is a notable increase in infection that surpasses the criteria for an endemic level within a defined population or area. These terms can also refer to a new infectious agent that emerges or reemerges. A **pandemic** is an epidemic that spreads worldwide (Centers for Disease Control and Prevention [CDC], 2012).

Pandemics have been recorded throughout history. One of the earliest occurred during the Peloponnesian War in 430 BCE as a disease, most likely typhoid fever, passed through Libya, Ethiopia, and Egypt and into Athens, killing as much as two-thirds of the population. The pandemic weakened the Athenians, contributing to their defeat by the Spartans (Onion et al., 2021). Throughout time, pandemics have shaped the course of history and society. The COVID-19 pandemic is the most recent example. This section discusses major pandemics throughout history, beginning with the bubonic plague and then focusing on the 20th- and 21st-century infectious pandemics that have shaped public health and policy.

The Plague

The plague, also called the bubonic plague and the Black Death, has caused a few distinct pandemics. The first recorded outbreak of plague, the Plague of Justinian (541–542), claimed the lives of half of Europe’s population (Piret & Boivin, 2020). Beginning in Egypt, it spread throughout the Roman Empire, killing an estimated 100 million people as it rapidly moved along trade and military routes. After this initial outbreak, the plague returned intermittently (Piret & Boivin, 2020).

Likely originating in East Asia, the Black Death pandemic spread through Central Asia and Europe via trade routes. In 1347, 12 ships from the Black Sea docked at a Sicilian port, with most of the sailors dead or ill, covered in boils oozing blood and pus. The authorities ordered the removal from port of these “death ships,” but it was too late. By this time in Europe, the Black Death had claimed an estimated 200 million lives (Frith, 2012; Piret & Boivin, 2020). In 1347, as the pandemic ravaged Europe, Africa, and Asia, officials in Ragusa, Italy, slowed its spread by isolating arriving boats and sailors for an initial 30, and later 40 days, or *quaranta*, the origin of quarantine (Frith, 2012; Hajar, 2012). By the 1350s, the plague had dissipated but continued to reappear intermittently.

- Successive waves of the plague from 1630 to 1722 affected France, Italy, the Netherlands, and England.
- Throughout the 1800s, outbreaks continued in Asia.
- In 1865, an outbreak began in Southern China and spread south and west. In 1893, the plague reached colonial India, where public health measures slowed its spread. Approximately 12 million people died during this pandemic (Frith, 2012; Piret & Boivin, 2020).

The plague is spread by a flea-borne bacteria, *Yersinia pestis*, that is associated with rodents. Fleas ingest an infected rodent’s blood and then transmit the bacteria to new rodent hosts. The plague has three presentations: bubonic, septicemic, and pneumonic. The most common bubonic form begins with flu-like symptoms followed by extreme lymph node swelling and oozing (plague-boils). Untreated, bubonic plague is often fatal. The plague can also present with a blood infection or progress from bubonic to a blood infection, classified as septicemia, with a high fatality rate if untreated. The extremely contagious, rapidly fatal pneumonic plague occurs when infection spreads to the lungs and is spread via droplet contact from person to person. The cause of the plague was unknown until 1897 when, during the plague pandemic in India, it was discovered to be caused by a bacterium (Frith, 2012).

Over the 19th and 20th centuries, sanitation and public health practices alleviated the plague’s high mortality rate and economic devastation, but they did not eradicate it completely. According to the CDC, most U.S. human plague cases occur in northern New Mexico, northern Arizona, southern Colorado, southern Oregon, and western Nevada. More than 80 percent of cases of plague are bubonic (CDC, 2022aa). From 2015 to 2020, 36 cases were documented in the United States, with six recorded deaths. Plague epidemics continue globally today; most cases

since 1990 have been in Africa among individuals living in small towns, villages, or agricultural areas (CDC, 2022aa). Many public health measures used during the COVID-19 pandemic, such as medical inspections, isolation of sick individuals, ship restrictions and quarantines, or the control of the movement of individuals and materials, originated during the Black Death (Frith, 2012; Piret & Boivin, 2020).

Influenza Pandemic of 1918

The avian vector-borne influenza pandemic of 1918, also called the Spanish Flu, was one of the most severe pandemics in recent history. Caused by the influenza A H1N1 virus, it spread globally in 1918–1919, coinciding with World War I (WWI) (CDC, 2019a). The overcrowding and global troop movements associated with WWI likely facilitated its global transmission. A main characteristic of this influenza virus was that it resulted in a high mortality in healthy people aged 20–40 (CDC, 2019a; Klein, 2020). Lack of a vaccine and treatment and the susceptibility of young, healthy adults created a public health crisis, resulting in almost 700,000 deaths in the United States and at least 50 million deaths globally (CDC, 2018a; CDC, 2019a). This flu lowered the average life expectancy in the United States by more than 12 years (Klein, 2020).

1918 FLU PANDEMIC

[Access multimedia content \(<https://openstax.org/books/population-health/pages/13-1-pandemics-throughout-history>\)](https://openstax.org/books/population-health/pages/13-1-pandemics-throughout-history)

This video describes this pandemic and how it changed history. As you watch this video, keep in mind it was produced before the COVID-19 pandemic.

Watch the video, and then respond to the following questions.

1. How was the 1918 flu pandemic similar to the COVID-19 pandemic?
2. Do you feel public health preparedness has evolved enough over the past 100 years? Explain your reasoning.
3. How well do you feel the CDC was prepared for the COVID-19 pandemic?

The response to the 1918 flu pandemic was fragmented. No pharmacologic treatments or vaccines existed, and the United States lacked a government agency dedicated to disease control and prevention. In the fall of 1918, the number of professional nurses deployed to military camps throughout the United States and abroad to aid in the war effort resulted in a significant nursing shortage, further exacerbated by the failure to use trained Black nurses (CDC, 2018a). The American Red Cross issued urgent requests for volunteers to assist in nursing the sick. In Philadelphia, where the pandemic hit hard, hundreds of corpses awaited burial in cold-storage plants that served as temporary morgues (CDC, 2018a). Many cities closed theaters, movie houses, and night schools and prohibited public gatherings. By the end of 1918, public health officials began educating the public about the danger of coughing, sneezing, and carelessly disposing of nasal discharge (CDC, 2018a). The American Public Health Association encouraged businesses to stagger their hours to prevent public transportation overcrowding (CDC, 2018a). Cities like San Francisco implemented mask mandates, physical distancing, isolation, quarantine, disinfection, and hygiene measures. The implementation of these measures and reporting of actual disease numbers were inconsistent (CDC, 2018a; CDC, 2019a). Although the military created field hospitals dedicated to soldiers infected with influenza to isolate them from healthy soldiers, more soldiers died from the flu than in combat ([Figure 13.2](#)) (National Archives and Records Administration, n.d.; CDC, 2019a). Finally, by the summer of 1919, the flu faded as immunity developed (CDC, 2019a).

FIGURE 13.2 During the 1918 flu pandemic, some clients were isolated in outdoor sick wards. (credit: “Influenza ward, Walter Reed Hospital, Wash., D.C. [Nurse taking patient’s pulse]” by Harris & Ewing/Library of Congress, No Known Restrictions)

Pandemic Viruses of 1957, 1968, and 2009

In 1957, 1968, and 2009, new strains of the flu virus to which people lacked immunity caused flu pandemics (CDC, 2019a; Jordan et al., 2019; see [Table 13.1](#)). Following the 1918 pandemic, public health policies and practices continued to improve with each subsequent pandemic due to surveillance and education, sanitation, and isolation strategies (Matta et al., 2020).

Name	Virus	Most at Risk	Estimated Deaths	Public Health Significance
Pandemic of 1957 <i>Asian Flu</i> Duration: 1957–1959	H2N2 Avian influenza A	Those with underlying heart or lung disease	<ul style="list-style-type: none"> 1 to 2 million global deaths 116,000 in the United States 	<ul style="list-style-type: none"> Disease surveillance measures rapidly recognized H2N2 as a new influenza virus Rapid vaccine development saved many lives
Pandemic of 1968 <i>Hong Kong Flu</i> Duration: 1968–1972	H3N2 Avian influenza A	Individuals > age 65 experience more severe illness, death	<ul style="list-style-type: none"> 1 million global deaths 100,000 in the United States 	<ul style="list-style-type: none"> Vaccine was developed in 1970 Virus continues to circulate as seasonal influenza A virus
Pandemic of 2009 <i>Swine Flu</i> Duration: 1968–1970	H1N1 Influenza A similar to 1918 strain but with new genes	Children, young-to middle-age adults (< 65)	<ul style="list-style-type: none"> 151,700–575,400 global deaths 12,469 in the United States 	<ul style="list-style-type: none"> Older adults had some immunity due to previous H1N1 infection This pandemic had less global impact Virus still circulates seasonally in the United States and has caused illness, hospitalization, and death

TABLE 13.1 Comparison of the Flu Pandemics of 1957, 1968, and 2009 (See CDC, 2019a, 2019b, 2019c, 2019d, 2019e; Jester et al., 2020; Jordan et al., 2019; Little, 2020; Piret & Boivin, 2020.)

HIV Pandemic

In June 1981, the CDC went on alert when five healthy young men in California developed *Pneumocystis carinii* pneumonia (PCP), a rare and often deadly disease. Health officials next recognized an unusual increase in Kaposi's sarcoma (KS) cases among gay men in New York. Outbreaks of these rare diseases were alarming, especially since they occurred within the same population (CDC, 2021a). The media and health care professionals used the term *gay-related immune deficiency* (GRID) to describe the new virus, resulting in severe stigmatization of the gay community (Ayala & Spieldenner, 2021). In late 1981, cases appeared in heterosexual intravenous (IV) drug users and, shortly thereafter, in individuals with hemophilia. In response, the CDC issued guidelines on the care of individuals with HIV, including wearing gloves when exposed to blood and other specific bodily fluids (CDC, 2021a). At the start of the pandemic, the median survival time for a person with AIDS was one to two years (Eisinger & Fauci, 2018). The identification in 1983 of a retrovirus that causes HIV led to the first HIV test in 1985 (Beyrer, 2021).

While the pandemic officially began in 1981, the infection is believed to have developed in the late 1800s from a chimpanzee virus in Central Africa that spread slowly, reaching the United States in the mid-to-late 1970s (CDC, 2022a). At that time, sporadic cases in the United States were not known to be caused by HIV (CDC, 2022a). In the 21st century, AIDS has become one of the largest public health challenges, killing more than 39 million people worldwide, including 500,000 in the United States (CDC, 2021a). Today, an estimated 1.2 million people in the United States (CDC, 2023a) and an estimated 39 million people globally, the majority in sub-Saharan Africa, live with HIV or AIDS (UNAIDS, n.d.). The United Nations (2022) reports that the "AIDS pandemic continues to be responsible for more than 13,000 deaths each week" (paragraph 1). Although the number of new HIV infections in the Sub-Saharan Africa has declined, and despite better treatment options and decreased U.S. mortality rates, HIV and AIDS is still a global pandemic (Eisinger & Fauci, 2018). HIV infections continue to expand in parts of eastern Europe, central Asia, the Middle East, and North Africa (Beyrer, 2021). While HIV can be managed with antiretroviral drug therapy, no current vaccine or cure for AIDS exists (CDC, 2021a).

HIV SURVIVORS REFLECT ON THE AIDS EPIDEMIC

[Access multimedia content \(<https://openstax.org/books/population-health/pages/13-1-pandemics-throughout-history>\)](https://openstax.org/books/population-health/pages/13-1-pandemics-throughout-history)

This ABC News video discusses the beginning of the AIDS epidemic, when this new disease created fear within the health care workforce and among many Americans. The video shows how fear and stigma around the illness prevailed for years.

Watch the video, and then respond to the following questions.

1. What parallels do you see between the AIDS epidemic and the COVID-19 pandemic?
2. After listening to the survivor's stories, what inequities in care can you identify that these individuals face?
3. Do you feel these inequities still exist today? Why or why not?

COVID-19 Pandemic

In December 2019, a cluster of individuals in Wuhan, China, began experiencing symptoms of an atypical pneumonia-like illness that was unresponsive to standard treatments. In January 2020, the WHO announced that these outbreaks were caused by the 2019 Novel Coronavirus, or 2019-nCoV (CDC, 2022e). The organization officially named the disease *COVID-19* and declared the outbreak a pandemic in March 2020, after it had affected over 100 countries and caused over 4,000 deaths. By August 2020, COVID-19 had become the third leading cause of death in the United States. More than 1,000 people died each day, with the number of confirmed cases surpassing 5.4 million. In a 10-month period, the reported mortality from COVID-19 exceeded 1 million globally ([Figure 13.3](#)) (CDC, 2022e).

Developing a vaccine to prevent COVID-19 became a global imperative. Approximately one year after the initial outbreak, in December 2020, the U.S. Food and Drug Administration (FDA) issued an Emergency Use Authorization for two different COVID-19 vaccines for people age 16 years and older.

Like other pandemics throughout history, COVID-19 helped shape the public health system and the government response to public health threats. Pandemic responses have led to advances like sanitation, isolation, quarantine,

and vaccine development and have taught public health workers lessons about the importance of early response and mitigation efforts to decrease morbidity and mortality. The HIV and AIDS pandemic shaped domestic public health policy by challenging the stigmatization of groups of individuals, protecting human rights, and ensuring scientific evidence guides the actions of public health with the dissemination of correct information on modes of transmission, prevention, and potential treatments (Somse & Eba, 2020).

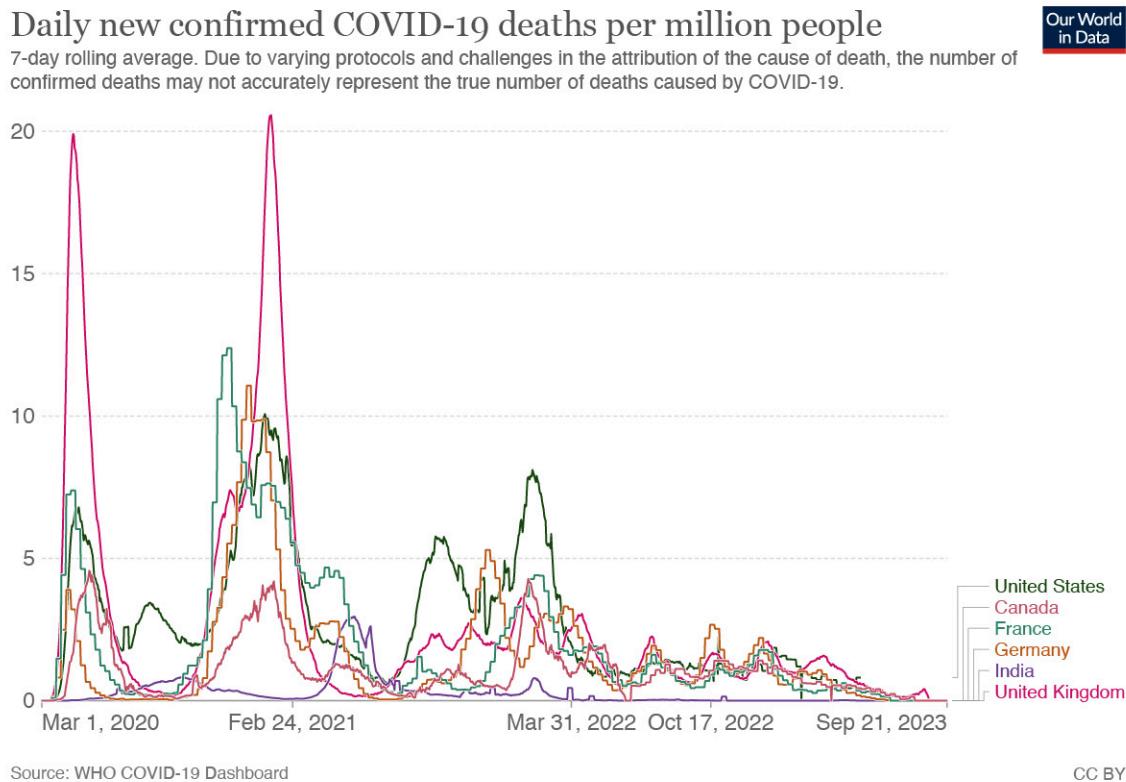

FIGURE 13.3 This chart presents COVID-19 deaths per million people from March 2020 through April 2023. (data source: World Health Organization, COVID-19 Dashboard; credit: “Daily new confirmed COVID-19 deaths per million people” by Our World in Data, CC BY 4.0 International)

13.2 Types of Infectious Disease Outbreaks

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 13.2.1 Define the term infectious disease.
- 13.2.2 Explain how infectious agents are transmitted.
- 13.2.3 Describe the types of infectious disease outbreaks.
- 13.2.4 Discuss the impact of vaccines on infectious disease control and prevention.
- 13.2.5 Explain the nurse’s role in infectious disease control and prevention.
- 13.2.6 Identify emerging infectious diseases and potential bioterrorism agents.

Diseases are **infectious** if they are easily transmitted between individuals. To understand how outbreaks of infectious diseases occur, community and public health nurses should understand disease communicability and transmissibility. Health promotion and disease prevention efforts are geared toward breaking the chain of transmission. To break this chain, nurses must implement appropriate public health measures based on the transmission mode and educate communities effectively on how to protect and prevent disease transmission. Public health nurses, like Sally, play a role in disease surveillance.

The Epidemiology (Communicability) of Infectious Diseases

Infectious diseases are caused by pathogenic microorganisms—agents such as bacteria, viruses, parasites, or fungi—that enter a human host, multiply, and cause infection that can spread via direct or indirect transmission

(CDC, 2022ap). [Epidemiology for Informing Population/Community Health Decisions](#) introduced the epidemiological triad and the chain of infection; both are central in the transmission of infectious disease. The epidemiological triad includes the host, agent, and environment and describes the *who*, *what*, and *where* of the infectious process. The chain of infection builds on this triad; a disease is considered communicable or contagious (capable of spreading from one person to another) if the infected host has a portal of exit, a means of transmission, and a portal of entry into another susceptible host. Some infectious diseases can be spread by germs in the air, food, water, or soil and by vectors or by animals to humans. While these diseases are still considered infectious, as they are caused by bacteria, viruses, parasites, or fungi, they are not considered communicable from person to person.

The agent's **pathogenicity** (the potential ability to cause disease in a susceptible host) depends on the agent's infectivity and its ability to invade the host, destroy host body cells, and produce toxins that result in the virulence, or severity, of the infectious disease.

The susceptibility of a host is a key component in the epidemiological triad and chain of infection. Susceptibility depends on many factors, such as age, sex, physical health, and immune status. Portals of entry and exit can include the skin, conjunctiva, respiratory tract, GI tract, genital tract, and vertical transmission during the birthing process. The environment is a component common to both the epidemiologic triad and the chain of infection. It refers to reservoirs of infectious agents, which may be humans, animals, plants, insects, water, and soil. The environment and any environmental changes can have a significant impact on the transmission of waterborne, foodborne, and vector-borne agents. Transmission of infectious agents includes airborne, direct contact, indirect contact, and droplet transmission. If an environment is favorable for the survival of an infectious agent and there is an opportunity for the host to be exposed to the agent, infection and disease will ensue (The Alliance for Child Protection in Humanitarian Action, 2018).

Common Communicable Diseases

As the COVID-19 pandemic showed, communicable diseases are a major global health and security threat, negatively impacting social and economic development (WHO, 2023b). Older communicable diseases such as tuberculosis (TB) remain global public health threats. Public health nursing is founded on the practice of promoting health, preventing disease and disability, and protecting the health of populations (Association of Public Health Nurses, 2022). Public health nurses require knowledge of communicable diseases and basic epidemiological principles to promote the health of individuals and communities by implementing measures to prevent and control the spread of communicable diseases.

Influenza

Influenza viruses cause influenza (flu) A and B, which result in a respiratory infection affecting the nose, throat, and lungs, causing mild to severe illness and sometimes death. Influenza viruses are categorized as follows:

- Influenza A viruses cause the most severe and widespread disease, undergoing minor mutations (**antigenic drift**) each year and periodically undergoing a major mutation (**antigenic shift**), which results in a flu pandemic.
- Influenza B virus often causes milder disease outbreaks, mutating gradually via antigenic drift but not undergoing antigenic shift.

Flu often occurs in the winter months but may be found year-round with testing. Each year, approximately 8 percent of the U.S. population becomes ill from flu viruses, with children twice as likely as adults over the age of 65 to develop symptomatic flu illness (CDC, 2022x). The seasonal incidence of flu changes based on the severity of the flu season. Seasonal flu is very different from pandemic flu. Seasonal flu viruses often undergo antigenic drift, necessitating an annual flu vaccine that is updated yearly to reflect current circulating influenza strains. In contrast, a major mutation resulting in a new influenza strain (antigenic shift), such as those that have occurred four times in the last 100 years, is often responsible for pandemic flu (CDC, 2022t). Hosts are more susceptible to these new disease strains as they often have little to no immunity against them (CDC, 2022t).

Flu is easily transmitted by droplets of infected material. When infected individuals talk, sneeze, or cough, infectious droplets can land in the mouths or noses of individuals nearby, spreading the disease. The flu can also be spread through indirect contact transmission (CDC, 2022x). Infected individuals are most contagious during the first three to four days of illness, but some are contagious beginning one day prior to symptom onset and up to seven days

after becoming ill. Anyone can get the flu, and serious problems may occur at any age. Older adults, children under five, pregnant persons, and individuals with chronic conditions such as asthma, diabetes, and heart disease are at higher risk for developing flu-related complications. Flu symptoms include fever, chills, cough, sore throat, nasal congestion, body aches, headaches, fatigue, and sometimes vomiting and diarrhea (CDC, 2022x).

Pneumonia

Pneumonia is a lung infection that causes mild to severe illness in individuals of all ages. Risk factors are age (older than 65, younger than five years), co-occurring chronic medical conditions, and cigarette smoking. Viruses, bacteria, and fungi are agents that can cause pneumonia. In the United States, the most common causes of pneumonia include:

- Viral: Influenza, respiratory syncytial virus (RSV), and SARS-CoV-2
- Bacterial: *Streptococcus pneumoniae* (pneumococcus), *Mycoplasma pneumoniae*, and *Chlamydophila pneumoniae*
- Fungal: Coccidioidomycosis found in Southern California and the Southwest deserts, histoplasmosis mostly found in the Ohio and Mississippi River Valleys, and cryptococcus found in soil contaminated with bird droppings (American Lung Association [ALA], 2022)

Some types of pneumonia are contagious, spreading via droplet transmission similar to the flu. Individuals may also spread pneumonia through indirect contact transmission, and not everyone exposed to pneumonia will develop active disease (ALA, 2022). In 2021, over 40,000 individuals died from pneumonia in the United States. Many of these deaths could have been prevented or avoided with vaccines and appropriate treatments (CDC, 2022ab). Current vaccine options for bacteria and viruses that can cause pneumonia include COVID-19, Haemophilus influenzae type b (Hib), influenza, measles, pertussis, pneumococcal (PCV), and varicella. PCV protects against 13 or 15 (PCV-13 vs. PCV-15) of the most common serotypes and is a part of the routine infant vaccination schedule, while the 23-valent pneumococcal polysaccharide vaccine (PPSV23) is available for individuals in high-risk groups.

Pneumonia symptoms vary greatly but may include fever, chills, a productive cough, shortness of breath, rapid or shallow breathing, sharp or stabbing chest pain, chest pain worsening with deep breathing or coughing, loss of appetite, fatigue, nausea and vomiting, and confusion (ALA, 2022). In 2019, pneumonia killed 2.49 million individuals globally, one-third of whom were children under age 5 making it a leading cause of death in this population (Dadonait & Roser, 2019). Within the United States, community-acquired pneumonia is a leading cause of hospitalization and results in significant mortality (Regunath & Oba, 2022).

Hepatitis

Hepatitis is inflammation of the liver and may result from a viral infection. In the United States, its most common viral forms are hepatitis A, B, and C ([Table 13.2](#)). Viral hepatitis infections affect millions of people globally, with hepatitis B and C resulting in chronic infections and liver cancer, disproportionately affecting lower-income countries. However, progress in treatment is being made globally. Hepatitis C is curable with a three-month course of medication taken once a day, and medications are available to slow the progression of hepatitis B and prevent liver damage (CDC, 2021e). Both hepatitis A and B can be prevented with safe, effective vaccines.

	Hepatitis A (HAV)	Hepatitis B (HBV)	Hepatitis C (HCV)
U.S. incidence in 2020	~ 19,900 estimated infections	<ul style="list-style-type: none"> ~ 14,000 new infections disproportionately affect individuals of Asian Pacific Islander descent; an estimated 880,000 cases of chronic HBV infection in adults, a leading cause of liver cancer. Most infants and 33% of children under age 6 with HBV will have lifelong chronic infection; children over 6 and adults usually recover completely. 	<ul style="list-style-type: none"> ~ 67,000 new infections and an estimated 2.2 million adults with chronic HCV infection, a leading cause of liver cancer occurred. Rates of HCV-related deaths were highest in BIPOC individuals.
Transmission	<ul style="list-style-type: none"> Ingesting the virus through contaminated food (fecal-oral route) or through person-to-person contact. Hepatitis A outbreaks are rare in the United States but common in many countries, especially those without adequate sanitation and water. 	<ul style="list-style-type: none"> Direct contact with infected blood, semen, other bodily fluids, or open sores, such as through the birthing process, sexual intercourse, sharing contaminated equipment (needles, syringes, toothbrushes, razors), and through poor infection control in health care facilities. HBV is not spread through kissing, sharing utensils, sneezing, coughing, or breastfeeding or through food or water (CDC, 2023p). 	<ul style="list-style-type: none"> Direct contact with infected blood such as through sexual contact, the birthing process, sharing contaminated equipment (needles, syringes), getting a tattoo or body piercing with contaminated instruments, or via poor infection control in health care facilities. Transmission could also occur through a blood transfusion or organ transplant prior to 1992.

TABLE 13.2 Comparison of Hepatitis A, B, and C in the United States in 2020 (See CDC, 2020f; CDC, 2022n; CDC, 2023e; CDC, 2023f; CDC, 2023p.)

	Hepatitis A (HAV)	Hepatitis B (HBV)	Hepatitis C (HCV)
Illness	<ul style="list-style-type: none"> Mild to moderate illness, lasting several weeks to several months. Most individuals recover without permanent damage, and death rarely occurs. 	<ul style="list-style-type: none"> Acute infection occurs within the first 6 months of exposure. Acute infection may be asymptomatic or result in mild to moderate disease, rarely causing severe disease. Up to two-thirds of all asymptomatic individuals may not know they are infected (CDC, 2023p). Symptoms include fever, fatigue, appetite loss, nausea, vomiting, abdominal pain, arthralgias, and jaundice. Acute infection can lead to chronic infection that could result in serious health issues of liver damage, cirrhosis, and liver cancer. 	<ul style="list-style-type: none"> Acute infection may last a few weeks or become a serious chronic condition. Usually asymptomatic or mild symptoms such as fever, fatigue, nausea, vomiting, abdominal pain, or arthralgia. Chronic disease develops in approximately half of adults yet usually remains asymptomatic or presents with nonspecific symptoms such as chronic fatigue and depression. 5–25% progress to cirrhosis over a 10 to 20-year period.

TABLE 13.2 Comparison of Hepatitis A, B, and C in the United States in 2020 (See CDC, 2020f; CDC, 2022n; CDC, 2023e; CDC, 2023f; CDC, 2023p.)

	Hepatitis A (HAV)	Hepatitis B (HBV)	Hepatitis C (HCV)
Prevention	A highly effective vaccine is typically incorporated into the routine childhood vaccination schedule.	Hepatitis B vaccination is a part of the routine infant and child vaccination schedule.	There is no vaccine available for hepatitis C.
Recommendations	<ul style="list-style-type: none"> • Vaccination for previously unvaccinated adults if at increased risk, such as individuals who experience homelessness, use illegal drugs, have occupational risk of exposure, travel internationally, or have chronic liver disease or HIV. • Men who have sex with men (MSM) are also identified as high risk. 	<ul style="list-style-type: none"> • Vaccination for all adults under age 60, but anyone may request it and receive it. • Universal screening at least once in the lifetime of all adults, and more often with ongoing risk factors such as pregnancy, hepatitis C infection, and individuals who are incarcerated, have a history of sexually transmitted infections, or have multiple sexual partners. 	<ul style="list-style-type: none"> • Universal screening at least once in the lifetime of all adults, and more often with risk factors such as pregnancy, IV drug use, concomitant HIV infection, children born to mothers with HCV infection, and any individual who received a blood transfusion or organ transplant prior to July 1992. • Available treatment involves once-daily medication for 2 to 3 months, resulting in 95% cure rates with minimal side effects.

TABLE 13.2 Comparison of Hepatitis A, B, and C in the United States in 2020 (See CDC, 2020f; CDC, 2022n; CDC, 2023e; CDC, 2023f; CDC, 2023p.)

HIV and AIDS

Human immunodeficiency virus (HIV) is a virus that attacks the body's immune system and, if untreated, progresses to acquired immunodeficiency syndrome (AIDS). No current cure or vaccine exists for HIV, but with proper treatment, it can be controlled and those affected can live long, healthy lives (CDC, 2022a). In the United States, an estimated 1.2 million individuals are infected with HIV, with almost 160,000 unaware of their HIV status (CDC, 2022s). Almost 40 percent of new HIV infections are transmitted by individuals who are unaware they have the virus. Risk factors include men having sex with men (MSM); individuals who have had anal or vaginal sex with an individual who is HIV+; having multiple sex partners; sharing needles, syringes, or other drug equipment; having a history of other STIs; and concomitant hepatitis or tuberculosis (TB) (CDC, 2022ah). The CDC recommends HIV testing for everyone between the ages of 13 and 64 at least once as part of routine health care and annual testing for individuals with risk factors (CDC, 2022r, 2022s).

HIV is transmitted through direct contact with infected blood and specific body fluids, most often through anal or vaginal sex or sharing needles, syringes, and other drug injection equipment. HIV transmission may also occur perinatally (pregnant person-to-child) during pregnancy, birth, or breastfeeding; however, this is now rare in the United States due to advances in HIV prevention and treatment (CDC, 2022a). The three stages of HIV infection include:

- Stage 1, acute HIV infection: Heavy HIV load in the blood, flu-like symptoms occurring 2–4 weeks after initial infection and lasting days or weeks. Individuals are very contagious during this time.
- Stage 2, chronic HIV infection (also called asymptomatic HIV infection or clinical latency): Individuals often

have no symptoms but can transmit HIV. Individuals who adhere to prescribed HIV treatment may remain at this stage and never progress to stage 3. Without treatment, this stage may last a decade or longer, or may progress faster.

- Stage 3, AIDS: individuals have a high viral load and damaged immune systems resulting in opportunistic infections or other serious illnesses. Without HIV treatment, individuals with AIDS generally survive 3 years (CDC, 2022a).

The three available HIV tests are antibody tests, antigen/antibody tests, and nucleic acid tests (NAT). While these tests are accurate, no test can detect HIV immediately after infection. HIV antibodies may be undetectable to existing tests for up to 90 days after infection. Antigen/antibody tests can detect HIV 18–45 days after exposure, and NAT can detect HIV 10–33 days post exposure. NAT should be considered for people who have had a recent exposure or possible exposure with early HIV symptoms (CDC, 2022s).

Antiretroviral therapy (ART) is an effective HIV treatment that reduces viral loads to undetectable levels, keeping the individual healthy and potentially at stage 2 (CDC, 2023g). ART is recommended for all individuals with HIV, as soon as possible after diagnosis, regardless of CD4 cell count levels, since it is associated with a large reduction in morbidity and mortality compared with those who defer treatment (CDC, 2023g). When ART therapy is taken as prescribed and in conjunction with undetectable viral loads, multiple studies have demonstrated no risk of oral, anal, or vaginal sexual HIV transmission (CDC, 2023g). ART therapy coupled with undetectable viral loads also reduces the risk of transmission during pregnancy, labor, and delivery by 99 percent (CDC, 2023g). Many individuals achieve undetectable viral loads within 6 months of beginning ART (CDC, 2023g). Treatment as prevention (TasP) helps keep individuals who are HIV positive healthy and helps them to avoid transmitting HIV to others. Some individuals with HIV refer to TasP as undetectable = untransmittable, or U=U (CDC, 2023g).

THE ROOTS OF HEALTH INEQUITIES

HIV

The U.S. HIV epidemic is marked by historical social injustices and disparate access to prevention, care, and treatment. The social determinants of health (SDOH) reinforce what the surveillance data demonstrate: inequities in HIV incidence, prevalence, and needs. Poverty, low education level, inequitable access to health care, and income inequality are factors related to HIV high-impact areas. Stigma, structural discrimination, and racism result in notable health disparities in individuals with HIV and AIDS. Deeper disparities are associated with intersectional identities such as being a Hispanic MSM or a Black woman living in the rural South.

- Gay and bisexual men are most disproportionately affected by the HIV epidemic. MSM represent 2 percent of the total U.S. population but account for 61 percent of all new U.S. HIV infections.
- Black individuals are the most affected racial/ethnic population, representing 14 percent of the total population but accounting for 44 percent of new infections, with an infection rate almost eight times higher than White individuals.
- Latino individuals account for 20 percent of all new HIV infections, an HIV rate three times higher than that of White individuals.
- Individuals who inject drugs represent 9 percent of all new HIV infections.
- Individuals who are transgender have an average prevalence rate of 28 percent among male-to-female women.
- The southern United States has experienced the highest rates of new HIV diagnoses over the past decade, and researchers have suggested that this may be attributed to the refusal of many of these states to expand Medicaid, the lack of access to health care providers in rural areas, low health literacy levels, high rates of sexually transmitted infections, and ongoing stigma associated with HIV.

(See CDC, 2020g and Sullivan et al., 2021.)

Tuberculosis

TB is caused by a bacterium, *Mycobacterium tuberculosis* (MTB), which often attacks the lungs but can attack any part of the body. TB is spread via airborne transmission. When inhaled, TB bacteria can settle into the lungs, grow, and spread to other parts of the body (CDC, 2022u). Anyone can become infected, but certain populations, such as

BIPOC individuals, individuals experiencing homelessness, and those living in congregate settings (correctional facilities, detention centers) are at higher risk of TB disease than the overall population (CDC, 2022p). Because TB infection does not always result in illness, it is often classified as latent TB infection (LTBI) vs. TB disease ([Table 13.3](#)). Individuals infected with MTB have an estimated 5 to 10 percent lifetime risk of becoming ill with TB disease. Some will have LTBI, others will clear the infection, and some, such as those with weakened immune systems (for example, individuals living with HIV, malnutrition, or diabetes) and individuals with alcohol use disorder and tobacco dependence, will have a higher risk of becoming ill with TB disease (WHO, 2022b). See [Caring for Vulnerable Populations and Communities](#).

	Latent Tuberculosis Infection	Active Tuberculosis Disease
Diagnostic Method	Positive skin or blood test indicating TB infection	Positive skin or blood test indicating TB infection Chest X-ray and sputum culture positive for MTB
Description	Presence of TB bacteria in the body, but the bacteria is inactive	Presence of actively replicating TB bacteria in the body
Symptoms	No symptoms; individuals are not ill and cannot transmit the bacteria to others	Symptoms of weight loss, fever, night sweats, cough, chest pain, hemoptysis Highly contagious
Treatment	Can be given medication to prevent the development of TB disease	Requires treatment
Prevalence	Affected an estimated 13 million individuals in the United States in 2022	2.5 cases per 100,000 persons in the United States in 2022, an increase from 2021 levels

TABLE 13.3 Comparison of LTBI and TB Disease (See CDC, 2023n, 2023o.)

Globally in 2021, 1.6 million individuals died from TB; it remains the 13th leading cause of global death and the second leading infectious killer after COVID-19 (WHO, 2022b).

TB may be detected through testing ([Table 13.4](#)).

TB Test Name	Type of Test	Mode of Test	Interpretation
Mantoux tuberculin skin test (TST)	Intradermal test for active TB or LTBI	Requires two visits to a health care provider. First visit: injection of small amount of tuberculin into the skin of the lower arm. Second visit: must occur within 48 to 72 hours to read skin test for a reaction. *Preferred test for children under 5 who have not received the bacille Calmette-Guérin (BCG), which may cause false positive reactions.	Positive skin test: individual has MTB but requires additional screening or testing to determine LTBI or TB disease. Negative skin test: LTBI and TB disease unlikely.
QuantiFERON®-TB Gold Plus (QFT-Plus) and T-SPOT®.TB test (T-Spot)	Blood tests for active TB or LTBI	Interferon-gamma release assays (IGRAs) blood tests. *Preferred for those who have received the BCG vaccine as it does not give false positive results in those vaccinated.	Positive TB blood test: individual has MTB but requires additional screening for symptoms of active TB, plus a chest X-ray to assess for signs of active disease. Negative blood test: LTBI and TB disease unlikely.

TABLE 13.4 Tuberculosis Tests (See CDC, 2022al.)

Despite its global presence, TB is curable and preventable (WHO, 2022b). Treatment takes anywhere from four to nine months and can be expensive without adequate health insurance, creating barriers for clients who are unable or unwilling to take medication for that duration or who cannot afford the cost of treatment (CDC, 2023m; Viney et al., 2019). Treatment for active TB disease often consists of multiple drugs, some with a high side effect profile. Inadequate treatment may result in treatment failure, ongoing transmission to others, and the development of drug resistance. Drug-resistant TB, which occurs when the bacteria become resistant to the antibiotics normally used to treat it, is a public health crisis. Drug resistance is more common in individuals who do not take their TB drugs regularly, in those who develop TB re-infection after being treated for TB in the past, and in individuals from areas of the world where drug-resistant TB is common (CDC, 2022i).

DRUG-RESISTANT TUBERCULOSIS

Access multimedia content (<https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks>)

The three classifications of drug-resistant TB are multidrug-resistant TB (MDR-TB), pre-extensively drug-resistant TB (pre-XDR TB), and extensively drug-resistant TB (XDR TB). In this video, Khayr reflects on his experience with LTBI that ultimately transformed into MDR-TB and his long journey to survivorship. The clip sheds light on the importance of adhering to medication treatment for LTBI.

Watch the video, and then respond to the following questions.

1. What might have changed Khayr's behavior when he first learned he had latent TB?
2. What do you feel is the nurse's role in preventing MDR-TB?

Role of the Nurse in Preventing Communicable Diseases

Educating the public is the nurse's first priority in preventing and mitigating many communicable diseases. Primary prevention of illness and disease focuses on the individual and the health and well-being of the entire community.

[Table 13.5](#) shows examples of primary, secondary, and tertiary prevention interventions for communicable diseases.

Primary Prevention

Educate individuals and communities on the importance of these disease-prevention behaviors.

	Seasonal Influenza and Pneumonia	Hepatitis A	Hepatitis B and Hepatitis C	HIV
Vaccination	<ul style="list-style-type: none"> • Seasonal influenza, COVID-19, Hib, measles, pertussis, and varicella • Pneumococcal, PCV-13, PCV-15, and PPSV23 	Hep A	Hep B	None
Education	<ul style="list-style-type: none"> • Frequent handwashing or hand sanitizing • Isolating oneself when ill • Staying away from ill individuals • Coughing or sneezing into the crook of the arm 	<ul style="list-style-type: none"> • Disease transmission; disease can be spread at daycare centers and restaurants from inadequate hygiene practices • Handwashing after changing diapers or using the bathroom 	<ul style="list-style-type: none"> • Not sharing needles, syringes, or equipment contaminated with infected blood • Not sharing toothbrushes or razors with an infected individual • Using appropriate protection if having sexual relations with an infected partner • Researching tattoo and body piercing parlors to ensure they have appropriate infection control measures in place 	<ul style="list-style-type: none"> • <i>Everything listed for Hepatitis B and C</i> • Treatment as prevention: HIV+ individuals who take ART as prescribed and have undetectable viral loads can help avoid transmission to their sexual partners. U = U. • Using appropriate protection if having sexual relations with an infected partner • Nurses also provide referrals for pre-exposure prophylaxis (PrEP) for HIV-negative sexual or drug-injecting partners

Secondary Prevention

Identify diseases early via screening, before the onset of signs and symptoms, allowing for early treatment to delay or avoid potential complications and helping decrease potential transmission to others.

	Hepatitis B and Hepatitis C	Tuberculosis	HIV
--	------------------------------------	---------------------	------------

TABLE 13.5 Prevention of Communicable Diseases

Referrals for	None.	None.	Pre-exposure prophylaxis (PrEP) for HIV-negative sex or drug-injecting partners
Screening for	<ul style="list-style-type: none"> • Hep B and Hep C at least once, more if necessary for risk factors or exposures • Substance use • Risky sexual behaviors • STIs as this may indicate unprotected sexual activity, thereby increasing risk of disease transmission 	<ul style="list-style-type: none"> • TB with either the tuberculin skin test or one of the blood tests 	<ul style="list-style-type: none"> • HIV at least once, more if necessary for risk factors or exposures • Risky sexual behaviors • STIs as this may indicate unprotected sexual activity, thereby increasing risk of HIV transmission • Substance use

Tertiary Prevention

Treatment to manage the disease post-diagnosis to slow or stop disease progression:

- Referrals for Hep A, B, or C treatment
- Referrals for HIV treatment
- Referrals for TB treatment

TABLE 13.5 Prevention of Communicable Diseases

Foodborne Diseases

Within the United States, foodborne illness is fairly common, with an estimated one out of every six individuals becoming ill from contaminated food or drinks and approximately 3,000 deaths related to foodborne illnesses each year (CDC, 2022b). [Table 13.6](#) describes the top pathogens responsible for foodborne illnesses and death.

Pathogens Causing Food Poisoning Illness	Pathogens Causing Food Poisoning-Related Deaths
Norovirus	Salmonella (non-typhoidal)
Salmonella (non-typhoidal)	Toxoplasma gondii
Clostridium perfringens	Listeria monocytogenes
Campylobacter	Norovirus
Staphylococcus aureus	Campylobacter

TABLE 13.6 Top Five Pathogens Responsible for Foodborne Illnesses and Death (See CDC, 2022l.)

Noroviruses

The highly contagious norovirus is the leading cause of vomiting and diarrhea from acute gastroenteritis in the United States across all age groups (CDC, 2023l). Each year, there are between 19 million and 21 million cases, with over 100,000 hospitalizations and approximately 900 deaths; these cases occur more commonly between November and April (CDC, 2021c; CDC, 2023l). Older adults and children under 5 are most likely to have complications related to norovirus. By age 5, one in 110,000 children will die from norovirus and one in 160 will be hospitalized (CDC, 2023k). Though they are often referred to as a “stomach bug” or “stomach flu,” none are related to influenza viruses (CDC, 2023l).

Norovirus is transmitted via the fecal-oral route through contaminated hands, food, or water or by contact with contaminated surfaces. The most common symptoms include nausea, vomiting, diarrhea, and stomach pain that

often resolves within 48 hours (CDC, 2023l).

Common settings for norovirus outbreaks include hospitals, long-term care facilities, restaurants, schools, childcare centers, colleges, and cruise ships. Foods commonly implicated are leafy green vegetables, fresh fruits, and shellfish (CDC, 2021c).

HEALTHY PEOPLE 2030

Safe Food Handling

Healthy People 2030 features many objectives related to [safe food handling](https://openstax.org/r/safefoodhandling) (<https://openstax.org/r/safefoodhandling>). These objectives highlight the importance of consumer education to prevent disease and focus on the importance of washing hands and surfaces and separating cutting boards when preparing food, cooking food to a safe internal temperature, and refrigerating food within two hours after cooking.

(See also CDC, 2022m.)

Non-typhoidal Salmonella

Salmonella bacteria are classified as “typhoidal” or “non-typhoidal.” Typhoidal salmonella serotypes cause typhoid fever. This discussion focuses on non-typhoidal salmonella, which causes an estimated 1.35 million illnesses and 420 deaths annually in the United States (CDC, 2022ae). For every confirmed positive lab test, an estimated 30 cases go unreported (CDC, 2022ad). Children under age 5 are more likely to become infected; this age group, adults over 65, and individuals who are immunocompromised are most likely to have severe infections (CDC, 2022ae).

Salmonella bacteria live in the intestinal tracts of humans, amphibians, reptiles, poultry, and other birds and in the feces of some animals (CDC, 2022ae) and infect individuals who do not wash their hands after contact with animals or animal feces. Salmonella can also be found in foods like chicken, turkey, beef, pork, eggs, fruits, and vegetables. Salmonellas contaminate an estimated one out of every 25 packages of supermarket chicken, infecting individuals if the contaminated chicken is not cooked thoroughly or if its juices leak onto surfaces or foods that are not cooked such as fruit and produce (CDC, 2022ad).

Salmonella illness, salmonellosis, results in a mild to severe diarrheal illness, acute gastroenteritis. Symptoms include sudden onset of diarrhea that may or may not be bloody, abdominal cramping, and fever. Less commonly, nausea, vomiting, and headache may be present. Diarrhea may last for days, increasing the risk of severe dehydration, especially in infants, young children, and older adults. Most individuals recover within seven days without antibiotic treatment; however, it can take months before bowel habits return to normal. Occasionally, salmonella infection can spread to other body areas, referred to as extra-intestinal infections, and it may be severe enough to cause disability and death (CDC, 2022ae).

SALMONELLA ILLNESS LINKED TO CHICKEN

[Access multimedia content](https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks) (<https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks>)

In this video, 14-year-old AJ and his mother tell their story of illness related to a multistate outbreak of salmonella from contaminated chicken.

Watch the video, and then respond to the following questions.

1. What was the role of the public health nurse in responding to foodborne illnesses?
2. What purpose did the actions of the public health department in response to AJ's case serve?
3. AJ's mother mentions several food safety measures she takes in the kitchen. What other measures can you think of that she does not mention?

Listeria Monocytogenes

The bacteria *Listeria monocytogenes* causes listeriosis, a serious but rare infection. In the United States, an estimated 1,600 individuals become ill with listeriosis each year, and 260 individuals die from it (CDC, 2023i). Listeriosis most often infects and sickens pregnant clients, their newborns, adults over 65, and individuals with

weakened immune systems. Listeriosis is usually a mild illness in pregnant people, but it may cause severe disease in the fetus or newborn. Sometimes listeriosis becomes invasive—causing sepsis, meningitis, or encephalitis—and affects other parts of the body (CDC, 2023i).

Listeria bacteria are difficult to remove from food processing facilities, where they will spread to food that touches contaminated surfaces (CDC, 2023i). Refrigeration does not kill *Listeria*, but the bacteria is easily killed by heating food to a high enough temperature (CDC, 2023i). Foods more likely to be contaminated with *Listeria* include soft cheeses; deli products such as sliced cold cuts or cheese; deli salads such as coleslaw, potato salad, tuna salad, and chicken salad; sprouts; unpasteurized milk and associated products; hot dogs; and fermented or dry sausages such as chorizo, pepperoni, and salami (CDC, 2023i).

Listeriosis often results in fever and diarrhea, similar to other foodborne illnesses, but it is rarely diagnosed. More often, it is only identified if it becomes invasive or occurs during pregnancy. Signs of invasive listeriosis are meningitis-like symptoms of headache, nuchal rigidity, fever, confusion, and convulsions. Invasive listeriosis is serious, requiring inpatient hospital care; it causes death in one in five infected individuals (CDC, 2023i). Pregnant people often experience fever and flu-like symptoms; however, listeriosis can lead to miscarriage, stillbirth, premature delivery, or life-threatening infections of the newborn. Listeriosis during pregnancy results in a fetal loss in 20 percent of the cases and results in newborn death in about 3 percent of the cases (CDC, 2023i).

Escherichia Coli

Escherichia coli (*E. coli*) bacteria are normally found in human and animal intestines. While most are harmless, some may cause diarrhea, respiratory illness, and urinary tract or bloodstream infections ranging in severity (CDC, 2022k). Older adults, children under age 5, those with weakened immune systems, pregnant persons, and individuals who travel to certain countries are at higher risk for infection, although it can affect anyone (CDC, 2022k). The six types of pathogenic *E. coli* strains that cause diarrhea are often called diarrheagenic *E. coli*. Of this group, Shiga toxin-producing *E. coli* 0157 (STEC) is most commonly associated with foodborne outbreaks. An estimated 265,000 STEC infections occur in the United States each year; however, the actual number is likely higher as many infected individuals do not seek medical care and, if they do, may not have their stool tested (CDC, 2022j).

STEC is transmitted through ingestion of tiny amounts of human or animal feces, such as through contaminated food, unpasteurized milk, untreated water, or contact with cattle or with the feces of infected individuals. The CDC recommends avoiding unpasteurized milk, unpasteurized apple cider, and soft cheeses made from raw milk as these carry a high risk of STEC infection. Individuals have contracted infections by swallowing lake water while swimming, touching the environment in petting zoos, not washing hands after changing diapers, and eating food prepared by people who did not follow hand hygiene after using the restroom. In the United States in 2021 and 2022, there were a total of seven STEC outbreaks. These outbreaks were associated with prepared food items such as packaged salads, baby spinach, cake mix, frozen falafel, ground beef, and other unknown food sources (CDC, 2022j).

STEC infections often cause diarrhea (which may or may not be bloody), stomach cramps, vomiting, and low-grade fever. Symptoms usually last five to seven days with illness severity ranging from mild to life-threatening. Typically, individuals will begin to feel ill three to four days after ingesting STEC. Between 5 and 10 percent of individuals will develop hemolytic uremic syndrome (HUS), a condition that can lead to kidney failure, about a week after symptoms first appear when the diarrhea is improving (CDC, 2022k).

CLIENT TEACHING GUIDELINES

Food Poisoning—Know the Signs

Recognize the following signs of mild to moderate food poisoning:

- Fever
- Diarrhea
- Stomach pain or cramps
- Nausea and vomiting

Recognize the following signs of severe food poisoning and see a health care provider:

- Fever higher than 102°F
- Bloody diarrhea
- Diarrhea lasting more than 3 days
- Frequent vomiting causing inability to keep liquids down
- Dehydration

If you think you got sick from food, report it to your local health department.

(See CDC, 2023d.)

Role of the Nurse in Preventing Foodborne Diseases

Providing appropriate education to clients is the number one priority for the nurse in preventing and mitigating many foodborne illnesses. Primary prevention of illness and disease serves not only the individual but also the health and well-being of the entire community. [Table 13.7](#) shows examples of primary, secondary, and tertiary prevention interventions for foodborne diseases.

Primary Prevention	
Against Norovirus, Salmonella, and <i>Escherichia coli</i>	Against Listeriosis
<ul style="list-style-type: none"> • Educate individuals and communities on the following topics: <ul style="list-style-type: none"> ◦ Follow the four steps to food safety: Clean, Separate, Cook, and Chill Guidelines (https://openstax.org/r/foodsafety) ◦ Wash hands well after using the restroom or changing a diaper ◦ Wash hands well after touching animals or animal environments or visiting a petting zoo or farm (<i>E. coli</i> and salmonella) ◦ Cook shellfish thoroughly (norovirus) ◦ Take precautions with food and water when traveling abroad (<i>E. coli</i>) ◦ Do not drink untreated water (<i>E. coli</i>) ◦ Do not swallow water when swimming in lakes, ponds, streams, backyard “kiddie” pools, or swimming pools (<i>E. coli</i>) ◦ Avoid unpasteurized dairy products, juices, and ciders (<i>E. coli</i>, Listeria) 	<ul style="list-style-type: none"> • Educate individuals and communities on the following topics: <ul style="list-style-type: none"> ◦ Heat deli meats and cheeses prior to eating ◦ Avoid eating soft cheeses or cheeses made with unpasteurized milk ◦ Heat all raw sprouts prior to eating ◦ Avoid consuming unpasteurized milk or juice and avoid eating deli salads if at high risk for severe listeriosis, such as pregnant or immunocompromised individuals
<ul style="list-style-type: none"> • Decrease community spread <ul style="list-style-type: none"> ◦ When ill and for 48 hours after symptoms stop, stay home and avoid preparing food for others ◦ Disinfect potentially contaminated areas within the household 	
Secondary Prevention Against Salmonella and <i>E. coli</i>	
<ul style="list-style-type: none"> • Health department screening and initiation of food recalls 	

TABLE 13.7 Prevention of Foodborne Disease

Tertiary Prevention Against Foodborne Illnesses Requiring Hospital-Level Care

- Treatment and prevention of complications
 - Close monitoring for evidence of complications
 - Antibiotics as indicated or ordered
 - Oral hydrating solutions
 - Potentially IV fluid and electrolyte replacement

TABLE 13.7 Prevention of Foodborne Disease

Vector-Borne Diseases

Vector-borne diseases are illnesses caused by infections transmitted by **vectors**, living organisms such as ticks and mosquitos that feed on human or animal blood (WHO, 2020). When vectors ingest infectious pathogens via blood from an infected host, they can transmit the pathogens to a new host. Once infectious, vectors can often transmit the disease for the remainder of their lives during each subsequent bite of a new host (WHO, 2020). Globally, vector-borne diseases are responsible for over 17 percent of all infectious diseases, causing more than 700,000 annual deaths (WHO, 2020). Global travel and urbanization have contributed to increasing vector-borne diseases, making everyone susceptible to diseases spread by mosquitos and ticks (CDC, 2019i, 2020b). In the United States, vector-borne diseases more than doubled from 2004 to 2018. The CDC reported nearly 650,000 cases between 2004 and 2016, with a high likelihood that the actual number was significantly higher due to underreporting.

Lyme Disease

Lyme disease is the most commonly reported vector-borne illness in the United States, with approximately 300,000 annual infections (CDC, 2019i). It is most often found in the Upper Midwest, Northeast, and Mid-Atlantic, where it is spread by the *Ixodes scapularis* tick. The *Ixodes pacificus* tick is implicated in cases in northern California, Oregon, and Washington (CDC, 2022y). The geographic range of the ticks that spread Lyme disease is expanding, due in part to a changing landscape and climate (Johns Hopkins Bloomberg School of Public Health, n.d.).

Symptoms of early localized disease, within a month after the tick bite, include fever, chills, fatigue, headache, myalgias, arthralgia, lymphadenopathy, and **erythema migrans** (EM), a red, ring-shaped rash at the bite site that expands over several days, often to sizes greater than five centimeters in diameter with a central clearing that results in a “bull’s eye” appearance, although the rash can appear different on darker skin tones ([Figure 13.4](#), [Figure 13.5](#)). EM occurs in up to 80 percent of those infected with Lyme, but the classic rash is not always present (CDC, 2022y). Untreated or undiagnosed early Lyme progresses to disseminated disease in about 60 percent of clients, with symptoms appearing months after the tick bite. Disseminated disease may present with skin, neurologic, cardiac, or rheumatologic manifestations. Performing serologic testing for Lyme disease is recommended when disseminated Lyme disease is being considered. However, clinical diagnosis is recommended over serologic testing for clients who present with an EM rash after frequenting an area where Lyme is common (CDC, 2022y).

In a study by Ly (2021), the researcher found that Black clients with Lyme disease seem to be diagnosed later in the disease process than White clients. Black clients are more often diagnosed with disseminated disease upon initial diagnosis and appear to be diagnosed outside of the months that Lyme disease is most frequently diagnosed, reinforcing the idea that they are diagnosed later in the disease process. A study by Palmiere et al. (2019) looked into missed and delayed Lyme diagnoses in dark-skinned populations of Appalachia with findings that echo the work by Ly. A potential reason for these missed or delayed diagnoses may be related to the varying appearance of EM in individuals with dark skin (Minority Nurse, 2013). The EM is an early sign of Lyme disease, whereas late symptoms include arthritis and neurological symptoms. Ly (2021) found that 34 percent of Black clients were diagnosed with neurological symptoms in comparison to only 9 percent of White clients, reinforcing the earlier diagnosis in White clients (Eldred, 2022; Ly, 2019). Another study showed similar findings among Black children—that they were less likely to be diagnosed with Lyme disease and were more likely to be diagnosed with the arthritis manifestations related to Lyme disease and not the skin or cutaneous manifestations (Hunt et al., 2023). It is imperative that nurses remain aware of the risks of Lyme disease in all clients and educate clients who are darker skinned on the signs and symptoms of Lyme disease to be aware of. Early diagnosis of Lyme disease and proper treatment with antibiotics usually results in a rapid and complete recovery (CDC, 2022y). Education on tick bite prevention and tick removal can help prevent spread of the disease.

FIGURE 13.4 A bull's-eye rash (erythema migrans) is often a characteristic sign of Lyme disease. (credit: CDC, Public Domain)

FIGURE 13.5 The appearance of erythema migrans can vary and appear different on dark skin tones, which may be a factor in the late diagnosis of Lyme disease in individuals with darker skin. (credit: modification of work by CDC, Public Domain)

West Nile Virus

Spread by the bite of an infected mosquito, the West Nile virus (WNV) is the leading cause of mosquito-borne disease in the United States. The disease is now considered native to the United States, with outbreaks reported each summer through the fall (CDC, 2019i). Mosquitos become infected with WNV by feeding on infected birds and then spread it to people and animals by biting them. In rare cases, WNV has been spread through blood transfusion, organ transplant, and perinatal transmission from mother to baby during pregnancy, delivery, or breastfeeding. It is not spread through droplets, by touching live animals or birds, or by eating infected animals (CDC, 2022am).

Although most infected individuals have no symptoms, one in five experiences fever, headache, body aches, vomiting, and diarrhea. Serious, sometimes fatal, disease occurs in one out 150 infected individuals, and of this

group, one out of 10 die (CDC, 2022am). This severe infection often affects the central nervous system (neuroinvasive disease), causing encephalitis, acute flaccid paralysis, or meningitis. Recovery can take several months, and some effects may be permanent (CDC, 2022am).

WNV should be considered in any client with a febrile or acute neurologic illness with a recent exposure to mosquitos, blood transfusion, or organ transplant (CDC, 2023c). Lab diagnosis can be accomplished by testing the cerebrospinal fluid (CSF) and detecting WNV-specific IgM antibodies. Viral cultures and reverse transcriptase-polymerase chain reaction tests can be performed on blood specimens and confirm infection (CDC, 2023c). This is a **nationally notifiable condition**, a disease that, by law, must be reported to government authorities, allowing for case surveillance to assess transmission patterns and determine interventions to control outbreaks. Local and federal laws and regulations determine which diseases and conditions must be reported for case surveillance (CDC, 2022v). This will be discussed in more detail in the next section, [Infectious Disease Prevention and Control](#).

Zika Virus

The Zika virus is caused by infected *Aedes aegypti* and *Aedes albopictus* mosquitoes found throughout the United States (CDC, 2019i). It can be passed from a pregnant person to their fetus, and fetal infection during pregnancy may cause birth defects such as microcephaly and other severe fetal brain defects (CDC, 2022aq). Zika can also be passed from an infected person via sexual activity including vaginal, anal, and oral sex and sharing sex toys, but male and female condoms can reduce this risk. Sexual transmission is especially concerning as many individuals infected with Zika are asymptomatic and may be unaware they are infected. Blood or urine tests can confirm infection. In 2015–2016, a large outbreak of travel-associated Zika cases occurred in the United States, along with local transmission cases of Zika in Florida and Texas. In 2017, the number of Zika cases in the United States started to decline, and no cases of Zika transmission by mosquitos have been reported since 2018; however, Zika remains a global health threat (CDC, 2022aq).

Clinical findings in symptomatic disease include acute onset of fever with maculopapular rash, arthralgia, or conjunctivitis (CDC, 2019m). Other symptoms may include myalgias and headaches with clinical illness lasting a week or less. Zika infection during pregnancy causes severe fetal brain defects, including **microcephaly**, a condition where a baby's head is much smaller than expected, often resulting in abnormal brain development. Infants born to individuals with Zika infection during pregnancy must be evaluated for congenital infection and neurologic abnormalities (CDC, 2019m). Zika is a nationally notifiable condition reported to state and local health departments. No specific treatment for Zika exists as it is supportive in nature including rest, fluids, and use of analgesics or antipyretics. Those who are infected should be protected from further mosquito exposure for a few days after illness to prevent transmission to other mosquitos, thereby reducing the risk of local transmission (CDC, 2022aq).

Malaria

A mosquito-borne disease, malaria is caused by a parasite (*Plasmodium falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, and *P. knowlesi*) that frequently infects the Anopheles mosquito and is then transmitted to humans through this infected mosquito's bite (CDC, 2022z). It can also be transmitted through a blood transfusion, through an organ transplant, perinatally, or by sharing needles contaminated with blood. Malaria can result in serious illness and death (CDC, 2022z). *P. falciparum* causes the most severe malaria and is common in many African countries. Individuals living in poverty or rural areas lacking access to health care are at the greatest risk for life-threatening illness (CDC, 2022z). An estimated 241 million malaria cases occurred globally in 2020, with over 600,000 deaths. An estimated 90 percent of these deaths occurred in children under age 5 in sub-Saharan Africa, where the disease perpetuates a cycle of disease and poverty (CDC, 2022z). Almost half of the world's population is at risk for malaria, and lower-income countries are disproportionately affected (WHO, 2023a). Within the United States, approximately 2,000 cases are diagnosed yearly, with most cases occurring in immigrants and travelers returning from countries where malaria is endemic, such as sub-Saharan Africa and South Asia (CDC, 2022z).

Clinical findings in acute malaria include flu-like symptoms of fever, chills, headache, myalgias, fatigue, GI symptoms, and sometimes anemia and jaundice. Untreated malaria may cause kidney failure, seizures, mental status changes, coma, and death. *P. vivax* and *P. ovale* may result in relapsing malaria because these parasites can remain dormant in the liver and then come out of hibernation, resulting in acute illness (CDC, 2022z). Available malaria treatments are highly effective when started at the onset of symptoms (CDC, 2022z). Malaria is a nationally notifiable condition that must be reported to state health departments and the CDC through the National Malaria Surveillance System (NMSS). The CDC investigates locally transmitted malaria, such as transfusion malaria, and

supports health professionals in preventing, diagnosing, and treating malaria (CDC, 2020a). In June 2023, the CDC issued a health alert advisory notifying clinicians, public health authorities, and the general public about the identification of a handful of cases of locally acquired *P. vivax* malaria in Florida and one in Texas (CDC, 2023j). This was the first time in 20 years that a case of locally acquired malaria was identified in the United States. Although the risk of locally acquired malaria remains low, vigilance is needed to prevent mosquito bites (CDC, 2023j).

Role of the Nurse in Preventing Vector-Borne Diseases

The community health nurse is crucial in stemming disease burden from vector-borne diseases. Primary prevention can help to decrease the number of individuals infected with vector-borne diseases through education campaigns. Because no known treatments aside from supportive care exist for WNV or Zika virus, education and interventions are essential to prevent the spread of these diseases. [Table 13.8](#) shows examples of primary, secondary, and tertiary prevention interventions for vector-borne diseases.

Primary Prevention			
	Lyme Disease	West Nile Virus	Zika Virus
Educate individuals and communities on how to avoid insect bites	<ul style="list-style-type: none"> Use Environmental Protection Agency (EPA)-approved insect repellants containing DEET, picaridin, or oil of lemon eucalyptus. Wear clothing that covers the body and is treated with permethrin when entering grassy or wooded areas. Check the body daily for ticks. Shower after coming indoors. Teach how to remove ticks safely. Prevent ticks on family pets. Keep grass short. Create tick-safe zones by keeping play areas away from shrubs and bushes, clearing tall grass/brush around the home, placing wood chips or gravel between lawns and wooded areas, using tick pesticides, and discouraging deer. 	<ul style="list-style-type: none"> Use EPA-approved insect repellants containing DEET, picaridin, or oil of lemon eucalyptus. Keep body parts covered with loose-fitting, long-sleeved shirts and pants. Use clothing treated with permethrin. Control mosquitoes indoors and outdoors by using screens and removing any standing water from your property. 	<ul style="list-style-type: none"> Use EPA-approved insect repellants containing DEET, picaridin, or oil of lemon eucalyptus. Review geographic locations where Zika is more prevalent; pregnant persons and those who wish to become pregnant within a short-defined period of time should avoid these locations during travel.

TABLE 13.8 Prevention of Vector-Borne Disease

Educate individuals and communities on sexual transmission	N/A	N/A	<ul style="list-style-type: none"> Discuss risk of transmission via sex with an individual infected with Zika and that the only way to eliminate the risk of getting Zika from sex is abstinence. Educate on condom use to reduce the risk of transmission.
Secondary Prevention			
	Lyme disease	West Nile Virus	Zika Virus
Educate individuals and communities on signs and symptoms	<ul style="list-style-type: none"> For any bull's-eye rash, get evaluated. For any known tick bite and onset of symptoms such as fevers, chills, myalgias, etc., get evaluated by a health professional. 	<ul style="list-style-type: none"> For any febrile illness with neurological symptoms and potential exposure to mosquito bites, blood transfusion, or organ transplant, get evaluated by a health professional. 	<ul style="list-style-type: none"> Fever with a maculopapular rash, arthralgias, conjunctivitis, myalgias, and headaches. For any symptoms in a pregnant client who has recently traveled to active Zika areas or had sex with someone who lives in or recently traveled to areas with a risk of Zika, diagnostic testing should be performed.
Routine screening	<ul style="list-style-type: none"> Routine screening is not recommended. 	<ul style="list-style-type: none"> Routine screening is not recommended. 	<ul style="list-style-type: none"> Screening is generally not recommended for asymptomatic pregnant clients regardless of travel status.

Tertiary Prevention

- Lyme disease, WNV, and Zika require referral for treatment and support.
- With confirmed Zika in a pregnant client, screening the newborn for any congenital or neurological deficits is imperative.

TABLE 13.8 Prevention of Vector-Borne Disease

Waterborne Diseases

Many individuals become ill each year from waterborne diseases (CDC, 2020h). In the early 20th century, pathogens in drinking water caused most waterborne illness such as cholera and typhoid, but consistent sanitation measures and drinking water treatment have made these conditions rare in the United States. The Safe Drinking Water Act of 1974 also allows the EPA to set and enforce standards for drinking water quality (CDC, 2022h).

The CDC estimates that one out of 44 individuals become sick from waterborne diseases each year, and an estimated 7,000 people die from waterborne-related illnesses (CDC, 2020c; CDC, 2020e). The two most common types are respiratory or intestinal in nature. Legionella is the leading cause of drinking water outbreaks, and cryptosporidium is a leading cause of intestinal waterborne disease (CDC, 2019j; 2019l; 2022ai).

Today in the United States, waterborne pathogens infect individuals when they breathe in contaminated water droplets (as in heating and cooling systems) or when infected water gets in the ears or nose from recreational water

sports and swimming (CDC, 2020e).

CHOLERA: THE PANDEMIC THE WORLD HAS FORGOTTEN

[Access multimedia content \(<https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks>\)](https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks)

Globally, drinking water access and safety are not guaranteed, and clean water is scarce in many places. Safe drinking water is characterized by an adequate supply of affordable clean drinking water free of pathogens and chemicals located near the home (WHO, 2023c). According to the WHO (2019), one in three individuals, 2.2 billion globally, lack access to safely managed, contaminant-free drinking water. Cholera is responsible for seven distinct pandemics over the past two centuries (WHO, 2022a). In this video, Dr. Anita Zaidi discusses the origins, transmission, symptoms, treatment, and prevention and control efforts.

Watch the video, and then respond to the following questions.

1. Why are so many individuals still affected today by this preventable disease?
2. What is the link between cholera pandemics and the global social determinants of health?

HEALTHY PEOPLE 2030

Environmental Conditions

Healthy People 2030 includes important objectives related to [water safety \(<https://openstax.org/r/environmentalconditions>\)](https://openstax.org/r/environmentalconditions) under the priority area of social determinants of health and environmental conditions. The objectives highlight the need to increase the number of people who have access to water that meets the Safe Drinking Water Act. Objectives include:

- Increase the proportion of people whose water supply meets Safe Drinking Water Act regulations.
- Reduce health and environmental risks from hazardous sites.
- Reduce the number of toxic pollutants released into the environment.

Legionnaires' Disease

Legionnaires' disease is a dangerous type of pneumonia caused by *Legionella bacteria*. Normally found in lakes and streams, *Legionella* become a health concern when they grow and spread in water systems, such as sink faucets, centralized building cooling towers, decorative fountains, hot water tanks, and heaters. As *Legionella* grow and reproduce, water containing the bacteria can spread in droplets (CDC, 2021f). Individuals can also become ill by aspirating drinking water containing *Legionella*. Legionnaires' disease symptoms often begin within two weeks post exposure, are similar to other types of pneumonia, and include cough, shortness of breath, fever, myalgias, and headaches; some individuals experience diarrhea, nausea, and confusion (CDC, 2021f). While easily treated with antibiotics, Legionnaire's disease causes death in one in 10 individuals who contract it (CDC, 2021f).

Cryptosporidium

Cryptosporidium (Crypto) is a microscopic parasite that causes cryptosporidiosis, a diarrheal disease. Protected by an outer shell, the parasite can survive outside a host's body for long time periods and avoid disinfection with chlorine (CDC, 2019j). Crypto parasites are found worldwide and in every U.S. region, where an estimated 823,000 cases occur each year. Anyone can become sick with crypto, but individuals who are immunocompromised are more likely to have severe symptoms (CDC, 2019j). High-risk populations include children attending childcare centers, childcare workers, older adults, hikers who drink unfiltered and untreated water, individuals who drink from untreated shallow wells, swimmers, individuals who handle infected cattle, and international travelers (CDC, 2019j).

Crypto is transmitted by the fecal-oral route. The parasites live in an infected host's intestines; the host will shed millions of Crypto parasites in a bowel movement. Many community outbreaks have been linked to consuming municipal or recreational water (CDC, 2019j). Causes of cryptosporidiosis may include:

- [Swallowing recreational water \(<https://openstax.org/r/healthywater>\)](https://openstax.org/r/healthywater) contaminated with crypto
- Drinking water contaminated by stool from an infected individual

- Swallowing something that has come in contact with an infected individual's stool
- Touching the mouth with hands after coming in contact with an infected individual's stool (CDC, 2019j)

Symptoms of cryptosporidiosis begin about a week following infection and include watery diarrhea, stomach cramping, dehydration, nausea, vomiting, fever, and weight loss; they usually persist for one to two weeks. Those who are immunocompromised may develop a more severe and sometimes fatal illness. Healthy individuals generally recover without treatment.

Role of the Nurse in Preventing Waterborne Diseases

The nurse, utilizing primary prevention, can educate individuals and communities on how to avoid waterborne diseases, similar to the role of the nurse in foodborne diseases. [Table 13.9](#) shows examples of primary, secondary, and tertiary prevention interventions for waterborne diseases.

Primary Prevention

Educate individuals and communities on water safety.

- Drink only treated or filtered water.
- Have private home wells checked regularly for water safety reasons.
- Ensure the water in swimming pools, hot tubs, and splash pads is treated.
- Avoid swallowing the water while swimming.
- Require all individuals to take a quick shower to rinse off the body prior to entering any pools.
- Educate families to ensure children who are not toilet trained wear swim diapers and are taken for bathroom breaks every hour to avoid defecation in the water.
- Reiterate that anyone with any diarrheal illness should be excluded from swimming in any recreational body of water.
- The CDC offers more [guidelines on Diarrhea and Swimming](https://openstax.org/r/diarrheal) (<https://openstax.org/r/diarrheal>).

Secondary Prevention

No screening tests or secondary prevention measures are recommended for waterborne diseases, but reinforcing the signs and symptoms that require follow-up from a health care provider can help ensure ill individuals receive timely assistance.

Tertiary Prevention

Tertiary prevention efforts focus on reducing the burden of disease by treating illnesses promptly and avoiding complications.

TABLE 13.9 Prevention of Waterborne Diseases (See CDC, 2021d.)

Sexually Transmitted Infections

Sexually transmitted infections (STIs), also called sexually transmitted diseases (STDs), are infections that transmit from person to person through vaginal, oral, and anal sex and less commonly through intimate physical contact (CDC, 2022f). An estimated one in five individuals in the United States are affected by STIs, with 26 million new STI cases in 2018 (CDC, 2022af). STIs are preventable, and many are easily treatable if diagnosed promptly. Some STIs do not cause obvious symptoms, while others only cause mild symptoms; therefore, screening is extremely important for sexually active individuals. Untreated STIs are associated with increased risk of HIV, chronic pelvic pain, and reproductive issues associated with pregnancy. In the United States, those most affected by STIs are people ages 15 to 24, gay and bisexual men, pregnant individuals, and racial and ethnic minority groups (CDC, 2022af). The eight most common STIs are chlamydia, gonorrhea, hepatitis B, herpes simplex virus type 2, HIV, human papillomavirus, syphilis, and trichomoniasis (CDC, 2022af).

Chlamydia

Caused by infection with *Chlamydia trachomatis*, chlamydia is the most frequently reported bacterial STI, resulting in cervicitis, urethritis, and proctitis. In 2018, there were an estimated 4 million chlamydia infections in the United States (CDC, 2022c). Many individuals are asymptomatic and do not seek testing. Screening is necessary to identify most infections and can reduce the rates of adverse outcomes in women. In women, untreated infections can lead to pelvic inflammatory disease (PID), tubal infertility, ectopic pregnancy, and chronic pelvic pain (CDC, 2022c). In men, untreated infections rarely result in major health problems but may cause infertility. Chlamydial infections are

most common in young people ages 15 to 24 and BIPOC individuals. In 2020, chlamydia rates for Black individuals were six times the rate seen in White individuals (CDC, 2022c).

Chlamydia is transmitted via vaginal, anal, or oral sex with an infected partner. Ejaculation is not necessary to transmit the infection. It can infect the pharynx, cervix, urethra, upper reproductive tract, rectum, and conjunctiva. Symptoms in women may include abnormal vaginal discharge and dysuria. Symptoms may include penile discharge, dysuria, and pain and swelling in one or both testicles in men. Symptoms of rectal chlamydia may include rectal pain, discharge, and bleeding. Pregnant individuals can pass chlamydia to their baby during childbirth, resulting in pre-term delivery, conjunctivitis, and pneumonia in the neonate (CDC, 2022c).

When used correctly and with each sexual encounter, condoms can reduce the risk of chlamydia. Avoiding oral, vaginal, and anal sex is the only way to prevent chlamydia. Being in a mutually monogamous relationship with a partner who does not have chlamydia also lowers one's risk (CDC, 2022c).

Gonorrhea

Caused by *Neisseria gonorrhoeae*, gonorrhea is the second most commonly reported bacterial STI. Approximately 1.6 new infections occurred in the United States in 2018, with more than half among individuals ages 15 to 24. Because many infections are asymptomatic, the true number of cases may be much higher than reported (CDC, 2022o). Any sexually active individual can become infected, but most cases are among teenagers, young adults, and Black individuals (CDC, 2022o).

Gonorrhea is transmitted via sexual contact with the penis, vagina, mouth, or anus of an infected partner. Ejaculation is not needed for transmission. It infects the mucous membranes of the reproductive tract in women and of the mouth, throat, eyes, and rectum of both men and women (CDC, 2022o). Gonorrhea can also be spread during childbirth. Infection in newborns may result in blindness, joint infection, or sepsis; treatment of gonorrhea in pregnant individuals reduces the risk of these complications.

Symptoms in women are often mild, nonspecific, and mistaken for bladder or vaginal infections. Initial symptoms include dysuria, increased vaginal discharge, and bleeding between menses. Symptoms in men occur one to 14 days after infection and include dysuria; white, yellow, or green urethral discharge; and potential testicular or scrotal pain indicative of concomitant epididymitis, a complication of urethral infection (CDC, 2022o). Rectal infection may also be asymptomatic or cause discharge, anal itching, pain, bleeding, or painful bowel movements. Pharyngeal infection may result in a sore throat or may be asymptomatic (CDC, 2022o). Complications of gonorrhea include PID in women, which may lead to chronic pelvic pain, infertility, or increased risk of ectopic pregnancy. In men, complications include epididymitis and infertility. Untreated gonorrhea can potentially spread to the blood, resulting in disseminated gonococcal infection (DGI), a life-threatening infection characterized by arthritis, tenosynovitis, and dermatitis (CDC, 2022o).

When used correctly and with every sexual encounter, latex condoms reduce the risk of gonorrhea. Avoiding oral, vaginal, and anal sex is the surest way to prevent gonorrhea. Being in a long-term, mutually monogamous relationship with a partner who does not have gonorrhea is another way to lower one's risk (CDC, 2022o).

HEALTHY PEOPLE 2030

Sexually Transmitted Infections

Healthy People 2030 has a focused goal of [reducing sexually transmitted infections \(<https://openstax.org/r/sexuallytransmitted>\)](https://openstax.org/r/sexuallytransmitted) and improving access to quality STI care. Data demonstrates worsening rates for three of the 22 objectives that apply to this goal: reducing syphilis rates in females, reducing gonorrhea rates in male adolescents and young men, and reducing congenital syphilis rates. These worsening rates have led to a push to increase screening for these diseases and to provide updated STI treatment guidelines for providers.

Syphilis

Rates of syphilis, a bacterial STI caused by *Treponema pallidum*, have steadily risen over the past 20 years. In 2021, the United States reported 176,713 cases, an approximately 73 percent increase over a four-year period (CDC, 2022ak). MSM accounted for 43 percent of all primary and secondary cases, but cases are increasing among heterosexual individuals. Congenital syphilis, another growing concern, occurs when a pregnant person passes

syphilis to the fetus. Over 2,800 cases of congenital syphilis were reported in 2021, a 185 percent increase since 2017 (CDC, 2022ak).

Syphilis spreads through direct contact with a syphilitic chancre (sore) that is usually located on or around the penis, vagina, anus, rectum, lips, or mouth (CDC, 2022ak). It is also transmitted during vaginal, anal, or oral sex and pregnancy. When a pregnant client has syphilis, the infection can spread to the fetus, resulting in a high risk of stillbirth or death shortly after birth. Untreated syphilis in pregnant clients results in infant death in up to 40 percent of cases (CDC, 2022ak). A newborn with congenital syphilis may be asymptomatic, but without immediate treatment, serious problems such as developmental delays, seizures, and death may ensue (CDC, 2022ak).

Often beginning three weeks after initial infection, symptoms may resemble those of many other diseases, yet they follow a typical progression, with each stage potentially lasting for weeks, months, or years. At any stage of infection, syphilis can invade the nervous system (neurosyphilis), the visual system (ocular syphilis), and the auditory and vestibular systems (otosyphilis). The four stages are as follows:

- The primary stage starts with a single or multiple firm, round, painless chancres located where syphilis entered the body that last three to six weeks and then heal, regardless of treatment. Without treatment, syphilis will progress to the secondary stage (CDC, 2022ak).
- In the secondary stage, lesions develop in the mouth, vagina, or anus, and skin rashes that are not usually itchy and may appear as rough red or reddish-brown spots appear on the palms of the hands and soles of the feet. They can be very faint, making them difficult to see. Condyloma lata—large, raised gray or white lesions—may develop in moist, warm areas such as the mouth, axilla, and groin. Other symptoms are fever, swollen lymph nodes, sore throat, headaches, weight loss, myalgias, fatigue, and patchy hair loss. These symptoms will resolve with or without treatment, but an untreated infection will progress to the latent and potentially tertiary stage of disease (CDC, 2022ak).
- In the latent stage, there are no visible symptoms, and without treatment, it will remain in the body. This stage can last for years.
- Tertiary syphilis may develop in some untreated syphilis infections, appearing 10 to 30 years after initial infection and affecting multiple organ systems. This stage is rare, but it can be fatal.

Condoms, when used correctly, can reduce the risk of syphilis; however, transmission can occur if the condom does not cover the lesions. Avoiding oral, vaginal, and anal sex is the only way to avoid syphilis. Being in a mutually monogamous relationship with a partner who does not have syphilis is another way to lower one's risk of getting syphilis (CDC, 2022ak).

THE ROOTS OF HEALTH INEQUITIES

The Tuskegee Syphilis Study

[Access multimedia content \(<https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks>\)](https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks)

In 1932, the U.S. Public Health Service (USPHS) authorized a study to evaluate the effects of untreated syphilis. Six hundred Black men from Tuskegee, Alabama, were selected to be a part of the study. These men were mostly poor sharecroppers with limited education. They were recruited under the false pretense that they were being treated for “bad blood.” Two-thirds of the men were confirmed to have syphilis but did not receive treatment despite the availability of penicillin, which by 1943 was the treatment of choice to cure syphilis.

Watch the video, and then respond to the following questions.

1. Why do you think the USPHS and the Tuskegee Syphilis Study investigators allowed this study to continue for 40 years while withholding treatment for 32 of those years?
2. Do you think these investigators would have conducted this study on higher-income or White individuals? Why or why not?
3. What role, if any, does nursing have in preventing this type of unethical medical research from occurring?

Role of the Nurse in Preventing Sexually Transmitted Infections

The nurse has an important role to play in preventing STIs, identifying them early, and getting them treated appropriately. The CDC provides guidelines for teaching clients about reducing [the risk of getting or transmitting STIs](https://openstax.org/r/prevention) (<https://openstax.org/r/prevention>). **Table 13.10** shows examples of primary, secondary, and tertiary prevention interventions for STIs.

Primary Prevention

Education regarding the transmission of STIs and how to avoid them

- Abstinence is the only way to be sure to avoid contracting an STI.
 - If sexually active, correctly and consistently using protection, such as a condom, with every sexual encounter can significantly decrease the risk of contracting an STI but does not eliminate the risk.
 - Any contact with a syphilitic chancre may result in transmission of syphilis.
 - Instruct clients to have conversations with their sexual partner(s) regarding the number of sexual partners and testing frequency.
-

Secondary Prevention

Screening for STIs

- Screen all sexually active women under the age of 25 for chlamydia and gonorrhea and retest three months after treatment for these infections.
 - Screening sexually active MSM annually at sites of contact (urethra, rectum) for chlamydia, at sites of contact (urethra, rectum, pharynx) for gonorrhea, and for syphilis. Additionally, screen every three to six months if at increased risk.
 - Adapt screening recommendations for transgender and gender diverse persons to anatomy, meaning extend the annual routine screening for chlamydia in cisgender women under the age of 25 to all transgender men and gender diverse individuals with a cervix.
 - Educate client at every visit that for any signs and symptoms of an STI, it is important to get evaluated and screened.
-

Tertiary Prevention

Prompt referral for treatment for any positive STI screening.

TABLE 13.10 Prevention of Sexually Transmitted Infections (See CDC, 2022w.)

HEALTHY PEOPLE 2030

Infectious Disease

Healthy People 2030 includes many [objectives related to infectious diseases](https://openstax.org/r/infectious) (<https://openstax.org/r/infectious>), STIs, and vaccination. Reducing the rates of hepatitis B and C deaths and the overall rate of viral hepatitis diseases along with decreasing the incidence of tuberculosis and pertussis are major goals. Healthy People also includes objectives related to increasing the number of individuals who get recommended vaccines and the maintenance of these vaccination records in an information system.

Vaccine-Preventable Diseases (VPDs)

The introduction of vaccines is a significant public health victory as many notifiable infectious diseases, such as diphtheria, measles, polio, tetanus, and rubella, have nearly been eliminated in the United States (CDC, 2022q). By the time a child reaches age 2, they can be vaccinated against 14 potentially life-threatening illnesses if the vaccine guidelines have been followed (CDC, 2022q). In adolescence, additional vaccines are available to prevent pertussis, meningococcal disease, and human papillomavirus. Since 2020, COVID-19 has remained in the top 10 leading causes of death, in the number three spot behind heart disease and cancer (CDC, 2023h). This illustrates the importance of monitoring for communicable disease and the role of public health in keeping individuals and communities safe.

The CDC (2022g) recommends vaccines to prevent the following [vaccine-preventable diseases](#)

(<https://openstax.org/r/globalhealth>) (VPDs):

- Hepatitis A
- Hepatitis B
- Human papillomavirus
- Influenza
- Hib (*Haemophilus influenzae* type b)
- Measles
- Meningococcal disease
- Mumps
- Pertussis
- Pneumococcal disease
- Polio
- Rotavirus
- Rubella
- Tetanus
- Varicella
- COVID-19

While vaccines are considered the best way to prevent diseases and outbreaks, not everyone gets vaccinated. Only 70 percent of children born in the United States in 2016 received their recommended vaccines by age 2 (CDC, 2022q). Non-Hispanic Black children were less likely to receive their early childhood vaccine series than non-Hispanic White children (CDC, 2022q). As fewer children are vaccinated, the United States has seen the reemergence of VPD outbreaks. Unvaccinated children risk becoming infected and transmitting these infectious diseases to others, including to individuals who are too young or too immunocompromised to be vaccinated.

GET VACCINATED AND PREVENT MEASLES

[Access multimedia content \(<https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks>\)](https://openstax.org/books/population-health/pages/13-2-types-of-infectious-disease-outbreaks)

Globally, measles remains a highly contagious disease, and each year, unvaccinated Americans contract it while traveling abroad and then spread it to other individuals who are unvaccinated (Vaccinate Your Family [VYF], 2022). Measles outbreaks have occurred more frequently in the United States over the past decade, often in communities with groups of unvaccinated individuals. In 2019, the CDC reported almost 1,300 cases of measles in 31 states, and of these individuals, 10 percent were hospitalized (VYF, 2022). This is concerning, especially for children under age 1 who are unable to be vaccinated. Prior to the measles, mumps, rubella (MMR) vaccine, three to 4 million individuals in the United States contracted measles, and about 500 died (VYF, 2022).

This video from the CDC demonstrates how unvaccinated individuals can transmit VPDs to the most vulnerable individuals in our communities—babies, individuals who are immunocompromised, and older adults.

Watch the video, and then respond to the following questions.

1. Which populations are most at risk of contracting measles? What makes them vulnerable?
2. As a nurse, what is your responsibility in relation to preventing measles?
3. How would you explain the importance of getting a measles vaccination to a client who is hesitant to get a vaccination?

An endemic disease in the United States, whooping cough (pertussis) is transmitted easily from person to person, with outbreaks occurring in schools, childcare centers, hospitals, and even in large geographic areas (CDC, 2022ao). Like any endemic disease, whooping cough may cause an outbreak, during which public health officials focus on protecting those at higher risk of getting sick and dying. Outbreaks are often difficult to identify; many cases go unreported because a variety of other illnesses cause similar symptoms. Whooping cough is a nationally notifiable disease with local and state health departments taking the lead on investigations. During an outbreak, public health nurses may be involved in active screening at schools, hospitals, and childcare centers to reduce exposure to individuals with pertussis, recommend timely medical evaluation, and promote prompt use of antibiotics to high-risk

close contacts.

In the United States, up to 20 babies die each year due to pertussis (VYF, 2022). To decrease the risk in young babies, the CDC recommends women receive Tdap vaccination during each pregnancy, preferably between the 27th and 36th weeks (CDC, 2022ao). Before routine vaccination, pertussis was one of the most common childhood diseases and a major cause of death in children. While the vaccine has decreased its incidence, immunity diminishes, highlighting the importance of receiving recommended vaccinations at the recommended times.

Nurses play a critical role in educating individuals and communities about the importance of adhering to the recommended vaccination schedule. This includes being fully informed of the vaccine schedule, indications, contraindications, and types of available vaccines. The CDC has published [You Call the Shots \(<https://openstax.org/r/vaccines>\)](https://openstax.org/r/vaccines), an interactive, web-based immunization training course for nurses and other health care professionals discussing VPDs and current recommendations for vaccine use. Holding immunization clinics, visiting clients in their homes, providing pre-school entry immunization reviews, and offering accessible and convenient community information sessions are pivotal to gaining acceptance by vaccine-hesitant individuals. Nurses should follow the guidelines on nationally notifiable diseases and prepare accordingly by ordering the appropriate vaccines and necessary supplies to administer them.

Emerging Infectious Diseases

Emerging infectious diseases (EIDs) are those that are newly affecting populations or existing diseases that previously only caused isolated disease but are now significantly increasing in incidence and geographic range (National Institute of Allergy and Infectious Diseases [NIAID], 2018; Wang et al., 2021). Bioterrorism Category A, B, and C priority pathogens are also considered EIDs ([Table 13.11](#)) (NIAID, 2018). Because these diseases are new or were once less common, there are often minimal effective treatments and no cures. Without the benefit of prior knowledge and a lack of immunity, health care providers often contract EIDs as they tend to ill clients (WHO, 2014). Many EIDs are zoonotic in origin, emerging from animals and crossing the species barrier to infect humans (WHO, 2014). EIDs remain a global health threat as they can spread rapidly, posing a risk to the health and development of every country. As the COVID-19 pandemic has demonstrated, infectious diseases can cause significant death and disability and wreak havoc on the world economy, disrupting every level of society. [Table 13.12](#) lists some emerging infectious diseases (Wang et al., 2021).

	Category A Pathogens	Category B Pathogens	Category C Pathogens
Definition	Organisms/biological agents that pose the highest risk to public health and national security	Pathogens that are the second-highest-priority organisms	Pathogens that have the third-highest priority; include emerging pathogens that could be engineered for mass dissemination
Characteristics	Easily disseminated and transmitted from person to person, resulting in high mortality rates and potentially causing public panic and social disruption, requiring special action for public health preparedness	Moderately easy to disseminate, resulting in moderate morbidity rates and low mortality rates, requiring enhanced diagnostic capacity and disease surveillance	Easily available, easy to produce and disseminate, with the potential for high morbidity and mortality rates resulting in a major health impact
Examples	<ul style="list-style-type: none"> • <i>Bacillus anthracis</i> (anthrax) • <i>Clostridium botulinum</i> toxin (botulism) • <i>Yersinia pestis</i> (plague) • <i>Variola major</i> (smallpox) • <i>Francisella tularensis</i> (tularemia) • Viral hemorrhagic fevers 	<ul style="list-style-type: none"> • <i>Burkholderia pseudomallei</i> (melioidosis) • <i>Coxiella burnetii</i> (Q fever) • <i>Brucella</i> species (brucellosis) • Epsilon toxin (<i>Clostridium perfringens</i>) • Ricin toxin (<i>Ricinus communis</i>) • Typhus fever (<i>Rickettsia prowazekii</i>) • Food and waterborne pathogens such as Diarrheagenic <i>E. coli</i>, pathogenic vibrios, <i>Shigella</i> species, <i>Salmonella</i>, <i>Listeria monocytogenes</i>, hepatitis A, <i>Cryptosporidium parvum</i>, <i>Giardia lamblia</i>, and <i>Toxoplasma gondii</i> • Mosquito-borne viruses such as WNV, Eastern Equine Encephalitis, Japanese encephalitis virus, yellow fever virus, and Chikungunya virus 	<ul style="list-style-type: none"> • Nipah and Hendra viruses • Hantaviruses • Tick-borne hemorrhagic fever viruses such as bunyaviruses and flaviviruses • Tick-borne encephalitis complex flaviviruses • Tuberculosis, including drug-resistant TB • Influenza virus • Rabies virus • Prions • Severe acute respiratory syndrome associated coronavirus • Antimicrobial resistance

TABLE 13.11 Bioterrorism EIDs/Pathogens

Infectious Disease	Pathogen	Primary Transmission
Hantavirus pulmonary syndrome	Hantavirus	Zoonotic
Hendra virus infection	Hendra virus	Zoonotic
Nipah virus infection	Nipah virus	Zoonotic
Highly pathogenic avian influenza	H5N1, H7N9 influenza virus	Zoonotic

TABLE 13.12 Emerging Infectious Diseases

Infectious Disease	Pathogen	Primary Transmission
Severe acute respiratory syndrome	SARS-CoV-1	Respiratory droplet
Middle East Respiratory Syndrome	MERS-CoV	Zoonotic
Lyme disease	Borrelia	Vector-borne
Bartonellosis	Bartonella	Zoonotic
<i>Cryptococcus gattii</i> infections	<i>Cryptococcus gattii</i>	Environmental
Cyclosporiasis infections	<i>Cyclospora cayetanensis</i>	Foodborne, waterborne
Variant Creutzfeldt-Jakob disease	Prion	Zoonotic, foodborne

TABLE 13.12 Emerging Infectious Diseases

13.3 Infectious Disease Prevention and Control

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 13.3.1 Define public health surveillance.
- 13.3.2 Explain the steps in public health surveillance for infectious diseases.
- 13.3.3 Describe how an outbreak is established.
- 13.3.4 Discuss the steps in an outbreak investigation.
- 13.3.5 Describe efforts to prevent foodborne and waterborne diseases.
- 13.3.6 Explain the nurse's role in emergency preparedness and disaster response during an infectious disease outbreak.

In the 20th century, improvements in sanitation and hygiene, the discovery of antibiotics, and the implementation of immunization programs resulted in disease control and a major shift in life expectancy and the diseases causing death (CDC, 1999). By 1900, 40 states had established health departments, and from the 1930s to the 1950s, they oversaw progress in sewage disposal, water treatment, food safety, and handwashing and food-handling education. Improvements in housing and TB-control programs decreased the incidence of TB deaths (CDC, 1999). In addition to these public health achievements, 1946 saw the creation of the Communicable Disease Center (CDC) with a primary mission of preventing the spread of malaria (CDC, 2018c). Over the next 40 years, the CDC provided disease surveillance and immunization programs. In 1992, it was officially renamed the Centers for Disease Control and Prevention to reflect its leadership in public health initiatives (CDC, 2023b). Communicable disease control and prevention is one of the greatest public health achievements of the 20th century (CDC, 1999). The development of new vaccines has continued into the 21st century, resulting in fewer serious illnesses and deaths due to VPDs. Eight of the 10 [leading causes of death \(<https://openstax.org/r/injury>\)](https://openstax.org/r/injury) for 2021 were related to chronic diseases, a significant shift from the last century (CDC, 2023h). Chronic diseases such as heart disease and cancer are leading causes of death and disability and the primary drivers of annual health care costs (CDC, 2021b). This evolution in infectious disease prevention and control would not have occurred without the efforts of public health professionals who recognized the importance of sanitation, education, vaccine development, and public health surveillance.

Public Health Surveillance

Public health surveillance is the “ongoing, systematic collection, analysis, and interpretation of health-related data essential to planning, implementation, and evaluation of public health practice” (CDC, 2018b, para 1) and more specifically refers to the monitoring of communicable diseases, noncommunicable diseases, injuries, and risk factors for these health outcomes in a population. Using data to monitor health problems is a key function of public health surveillance as it assists in prevention or control. Public health officials can use data to prioritize planning prevention and control programs (CDC, 2012).

Although numerous health issues affect global populations, many are neither urgent nor directly threaten health. Some health issues, such as breast cancer, are persistent and chronic, with a stable incidence and prevalence in the community. Therefore, the first step in public health surveillance is to identify which health problems to monitor. Selecting and prioritizing health problems for surveillance involves identifying issues that impact public health. The second step relates to the incidence, prevalence, severity, mortality, socioeconomic impact, and communicability of the disease or problem and the ability to prevent or control it. In general, communicable diseases are more

commonly under surveillance, given their possibility of causing an increased threat to public health. Within the United States, surveillance begins at local and state-level public health departments as each state sets local laws for diseases and conditions that must be reported. Local health departments work with laboratories, hospitals, and health care providers to obtain information on reportable diseases and then convey it to the state health department. The state health department uses the data to locate the source of a potential outbreak to prevent its spread and sometimes will involve the CDC, depending on the scope of the issue (CDC, 2022aj).

Local and state health departments are also responsible for notifying the CDC about agreed-upon notifiable diseases and health conditions. The [Council of State and Territorial Epidemiologists \(https://openstax.org/r/cste\)](https://openstax.org/r/cste) and the CDC identify this list together, and states voluntarily inform the CDC when an individual meets the criteria to become a case. The CDC then uses this data to monitor and alert communities about potential health threats (CDC, 2022aj). The CDC also partners with the WHO through the [Global Outbreak Alert and Response Network \(https://openstax.org/r/goarn\)](https://openstax.org/r/goarn) (Christensen et al., 2021).

The CDC conducts public health surveillance through the [National Notifiable Diseases Surveillance System \(https://openstax.org/r/nndss\)](https://openstax.org/r/nndss) (NNDSS) to track reportable and notifiable diseases and conditions with the assistance of local health departments. Currently, approximately 120 diseases are under NNDSS surveillance, including communicable and noncommunicable diseases and bioterrorism agents, with almost 2.7 million disease cases reported each year (CDC, 2022aj).

Each time a public health agency collects information about an individual diagnosed with a health condition that could threaten others, it is called **case surveillance**. This case surveillance is at the foundation of public health practice (CDC, 2022an). Recall John Snow's cholera outbreak investigation in London in [Epidemiology for Informing Population/Community Health Decisions](#). Case surveillance usually includes infectious diseases, such as COVID-19, or foodborne outbreaks, like *E. coli*. However, some noninfectious conditions are also surveilled, such as lead poisoning (CDC, 2022aj). Health departments notify the CDC to report instances of an estimated 120 diseases and conditions monitored under NNDSS surveillance. Case surveillance captures information about the population affected, the geographical area involved, and the course of illness and treatment that public health professionals can use to inform prevention and control efforts (CDC, 2022aj).

A surveillance **case definition** is a set of criteria used to define a disease for public health surveillance. Case definitions include clinical criteria such as expected signs or symptoms and often have restrictions by time, place, and person, especially in the setting of potential health threats to others. This enables public health officials to be consistent in case classifications and counting across states. Surveillance case definitions are not the criteria that health care providers use to diagnose, manage, and treat conditions in the clinical setting; they are used for data reporting and tracking purposes only (CDC, 2022ah). Surveillance data are also included in the CDC's [Morbidity and Mortality Weekly Report \(https://openstax.org/r/mmwr\)](https://openstax.org/r/mmwr) (MMWR) series. This publication is the agency's main dissemination of authoritative, useful public health information and recommendations. MMWR is targeted toward scientists, health professionals, epidemiologists, and public health professionals, including public health and community health nurses (CDC, 2023k).

THEORY IN ACTION

National Notifiable Diseases Surveillance System

[Access multimedia content \(https://openstax.org/books/population-health/pages/13-3-infectious-disease-prevention-and-control\)](https://openstax.org/books/population-health/pages/13-3-infectious-disease-prevention-and-control)

In this informational video by the CDC National Notifiable Diseases Surveillance System, Dr. Paula Yoon discusses current public health threats and efforts to control and prevent these threats.

Watch the video, and then respond to the following questions.

1. What is the role of the public health nurse in disease surveillance and reporting?
2. What contemporary examples of applying the National Notifiable Disease Surveillance System can you think of?
3. How does the National Notifiable Disease Surveillance System contribute to public health safety?

Outbreak Investigation

A disease outbreak refers to more cases of a certain disease or health condition than expected. Gathering surveillance data is one method of establishing the existence of an outbreak. This process can occur at the local or state health department and in hospital facilities looking to identify any hospital-acquired infections. Similarly, the CDC regularly reviews surveillance data and laboratory patterns of disease-causing organisms to detect clusters of illness. Another way to detect an outbreak is when a health care provider alerts the local health department about unusual cases—unusual due to the frequency or type of condition. An example is the 1999 WNV infection, which was discovered after a New York City health department received a call from a physician who had recently evaluated two clients with encephalitis (CDC, 2012, pp. 6–2). Community members may also call local health departments to report abnormal clusters of illness. An example is foodborne-related illness where an individual calls the health department and reports that seven of their friends are ill with similar symptoms after eating at the same restaurant. Another example would be a concerned community member reporting a cancer cluster in their neighborhood. A health department's decision to investigate a potential outbreak depends on many factors, such as illness severity, number of cases, mode of transmission, and availability of prevention and control measures (Figure 13.6). Typically, the more individuals affected or the more serious the illness, the greater the likelihood of an outbreak investigation with the ultimate goal to assist in disease prevention and control (CDC, 2012).

FIGURE 13.6 A team screens for disease by taking a nasal sample. (credit: by Kaylianna Genier/U.S. Navy/Flickr, Public Domain)

SOLVING THE PUZZLE: A STEP-BY-STEP GUIDE TO OUTBREAK INVESTIGATION

[Access multimedia content \(<https://openstax.org/books/population-health/pages/13-3-infectious-disease-prevention-and-control>\)](https://openstax.org/books/population-health/pages/13-3-infectious-disease-prevention-and-control)

This video breaks down the eight steps of an outbreak investigation.

Watch the video, and then respond to the following questions.

1. What are the steps in an outbreak investigation?
2. What are some reasons a nurse may see an increased number of cases of a certain disease compared with the baseline level normally seen?
3. What necessary information does the nurse need to describe an outbreak?
4. How are control measures utilized in an outbreak? Give some examples of control measures.

Surveillance for and Prevention of Foodborne Diseases

Prevention of foodborne diseases requires careful oversight and monitoring along the food supply chain. The CDC works collaboratively with the U.S. Department of Agriculture (USDA), the Food and Drug Administration (FDA), and local and state public health departments to ensure food safety along the steps in the food chain. This work involves

identifying foodborne illness, investigating multistate foodborne disease outbreaks, providing education to prevent outbreaks, and implementing systems to better address, detect, and stop outbreaks (CDC, 2022b). The CDC helps to track and investigate foodborne illnesses through the following surveillance systems:

- [PulseNet \(<https://openstax.org/r/pulsenet>\)](https://openstax.org/r/pulsenet)
- Foodborne Diseases Active Surveillance Network ([FoodNet FAST \(<https://openstax.org/r/foodnet>\)](https://openstax.org/r/foodnet))
- System for Enteric Disease Response, Investigation, and Coordination ([SEDRIC \(<https://openstax.org/r/outbreaks>\)](https://openstax.org/r/outbreaks))
- [Foodborne Disease Outbreak Surveillance System \(<https://openstax.org/r/fdoss>\) \(FDOSS\)](https://openstax.org/r/fdoss)

Whole genome sequencing (WGS) is an advanced technology that assists epidemiologists in finding foodborne outbreaks. WGS data helps scientists determine DNA similarities in strains of pathogens, indicating they come from the same source and allowing the CDC and its partners to detect outbreaks more quickly and to solve outbreaks while they are still small. When PulseNet scientists determine the same strain causes a group of illnesses, disease detectives can investigate the illness to determine if they came from the same food or food source ([Figure 13.7](#)). This has improved the ability to link foodborne illnesses and detect outbreaks (CDC, 2022b).

The CDC investigates multistate foodborne outbreaks using a seven-step process (CDC, 2022ag):

1. Detect a possible outbreak through data surveillance.
2. Find individuals included in the outbreak and look for additional ill individuals.
3. Generate hypotheses by interviewing ill individuals.
4. Test hypotheses by comparing what ill individuals ate to what well people of a similar group ate.
5. Solve by confirming the contaminated food using epidemiologic and lab information to identify the contamination point.
6. Control and stop the outbreak by recalling the food, cleaning or closing facilities, and educating those involved.
7. Decide the outbreak is over when illness ends and the contaminated foods are no longer available.

FIGURE 13.7 A disease detective works in the community to interview and gather data on a disease outbreak. (credit: “Disease Detectives in Guatemala” by CDC/Flickr, CC BY 2.0)

Surveillance for and Prevention of Waterborne Diseases

Preventing waterborne illnesses is multifaceted. Consumers need to know where their drinking water comes from and understand their water supply’s testing frequency and test results. Many community water systems use groundwater and are regulated by the EPA, but some municipal water supplies are unsafe, as was the case for years in Flint, Michigan (CDC, 2020d, 2022ac; Ruckart et al., 2019). Private wells must also be maintained and tested to ensure they are far enough away from septic tanks (CDC, 2022ac). The CDC provides guidance to consumers about ways to mitigate waterborne pathogens that can grow in pipes and devices that use water, such as humidifiers.

Pathogens thrive in stagnant water or water that is not treated with enough disinfectant. Due to EPA requirements, public water utilities provide water that meets certain quality and safety standards, but tap water is not sterile. The small number of pathogens in the water can congregate in pipes and potentially multiply, especially if taps are unused for long periods and water sits in the pipes (CDC, 2022ac).

CASE REFLECTION

Waterborne Illness

Read the scenario, and then respond to the questions that follow.

Janessa Jones is a 6-year-old client who presented to Dr. Liu's office complaining of a fever, abdominal cramping, vomiting, and diarrhea for the past two days. She is a generally healthy child with no significant medical history and does not take any medications on a daily basis. Sally, a public health nurse, received notification from Dr. Liu about the unusually high number of children presenting with similar symptoms in the past day. Janessa was the first child Dr. Liu evaluated with these complaints, but by the end of the day, she had seen eight children with similar presentations. Dr. Liu mentioned that each of the children had a recent history of swimming in the town's recreational pool.

1. What is Nurse Sally's role in this case?
 2. Identify Nurse Sally's next steps in addressing Dr. Liu's concerns.
 3. Discuss interventions the public health nurse can implement to reduce the risk of waterborne diseases.
-

A waterborne disease outbreak is defined when two or more individuals contract the same illness from the same contaminated water source. Waterborne disease surveillance data informs policy in developing drinking water regulations and regulations for certain recreational water activities (CDC, 2019f). The CDC oversees waterborne disease and outbreak tracking to help guide efforts to decrease and prevent future outbreaks. The national Waterborne Disease and Outbreak Surveillance System ([WBDOSS \(<https://openstax.org/r/cdchealthyw>\)](https://openstax.org/r/cdchealthyw)) collects data on waterborne illnesses related to recreational, drinking, and environmental water (CDC, 2019f). The WBDOSS also gathers information on hospitalizations, deaths, agents, types of water implicated, and water settings, which collectively inform next steps during an outbreak. Determining the etiology of waterborne illness is a complicated process as many pathogens spread by water can also be spread in other ways, making it difficult to link illness to water. Without an outbreak investigation, it is nearly impossible to link illness to water (CDC, 2019g). Therefore, anyone suspecting a possible outbreak is encouraged to contact their local health department, which will often enlist the assistance of the state health department (CDC, 2019h).

Waterborne disease outbreaks became nationally notifiable in 2009, and every state is responsible for identifying, investigating, and reporting them electronically through the CDC's National Outbreak Reporting System ([NORS \(<https://openstax.org/r/nors>\)](https://openstax.org/r/nors)). WBDOSS collects the data reported to NORS on waterborne disease and outbreaks associated with recreational water, drinking water, and non-recreational water exposures (CDC, 2019h) and publishes annual surveillance data reports in the MMWR (CDC, 2019k). These data have supported efforts to reduce waterborne disease outbreaks by assisting the EPA in developing drinking water regulations, guiding the CDC's recreational water activities program, and highlighting the emergence of *Legionella* outbreaks through various exposures and settings, supporting prevention efforts (CDC, 2019k).

Nurse's Role During an Infectious Disease Outbreak

Nursing plays a distinct role in pandemics and other infectious disease outbreaks. As part of the three core functions of public health nursing, nurses are involved with assessment in terms of epidemiological surveillance and detection, such as contact tracing. A school nurse working in New York City is credited with first observing and notifying the CDC about the 2009 H1N1 flu pandemic (National Academies of Sciences, Engineering, and Medicine [NASEM], 2021). During the COVID-19 pandemic, nurses conducted most contact tracing at the local board of health, at the state level, and in school districts. Public health nurses assist with coordinating and implementing disaster plans at the local and state levels, an aspect of policy development. Preparedness is a multidisciplinary effort to understand a health care system's capacity in advance of a public health emergency, including workforce capacity, access to personal protective equipment, and medical supplies, an aspect of assurance (NASEM, 2021).

During an evolving infectious disease outbreak, the nursing role may shift as health care shifts from routine care to public health care, emergency preparedness, and disaster response. Nurses working in various practice settings serve on the front line of public health emergencies, assisting individuals and communities through a crisis. Promoting health and well-being is one of the essential roles of nursing. Nurses engage and connect with individuals and communities to ensure they have what they need to be healthy (NASEM, 2021).

As the COVID-19 pandemic revealed, this engagement, ability, and willingness to respond to public health crises takes a toll on nursing; during that pandemic, many nurses reported feeling unsafe, unsupported, and unprepared, resulting in a profound mental health burden (NASEM, 2021). The COVID-19 pandemic required nurses to take on multiple roles: for example, outpatient endoscopy nurses were asked to care for medical-surgical clients, and non-critical care nurses were asked to care for critically ill clients. Nurses also provided end-of-life care and served as a means of communication between dying or ill clients and their families. This most recent pandemic has illustrated the vital importance of protecting nurses' well-being and mental health so that they can respond to disasters effectively and safely (NASEM, 2021).

Nurses also have a role within the health promotion and disease prevention framework along the three levels of prevention. Within an infectious disease outbreak, the public health nurse plays a vital role in primary, secondary, and tertiary prevention ([Table 13.13](#)).

Primary Prevention

- Administer immunizations if available
 - Educate individuals and communities regarding disease transmission and how to protect oneself
-

Secondary Prevention

- Engage in contact tracing to identify those at high risk for the disease to screen them
 - Screen for disease symptoms
 - Perform lab-based screening tests
-

Tertiary Prevention

- Provide direct bedside care and treatment of impacted individuals
-

TABLE 13.13 Prevention of Infectious Disease Outbreaks

HEALTHY PEOPLE 2030

Emergency Preparedness

Healthy People 2030 has a focused goal of [improving emergency preparedness and response](#) (<https://openstax.org/r/healthgov>) by building community resilience. The objectives are divided into the following categories of emergency preparedness: general, global health, health communication, and heart disease and stroke. Most of these objectives are in the developmental stage but recognize the value of individuals who are prepared for a disease outbreak.

Chapter Summary

13.1 Pandemics Throughout History

The lessons of pandemics throughout history have shaped how public health addresses emerging infectious disease threats. These lessons illustrate the vital need for public health organizations at the federal, state, and local levels to guide disease control and prevention efforts.

13.2 Types of Infectious Disease Outbreaks

Pathogenic microorganisms cause infectious diseases that spread by direct or indirect transmission. A disease is communicable if the infected host has a portal of exit, a means of transmission, and a portal of entry into another susceptible host. If an environment is favorable for the infectious agent's survival and opportunity exists for the host's exposure to it, infection and disease will ensue. Some infectious disease outbreaks result from direct contact with an infected individual's respiratory secretions, while others are transmitted through blood or bodily fluids. Still others result from an intermediary, such as vectors, water, or food. Breaking the chain of transmission is key to control and prevention of these illnesses and outbreaks.

Key Terms

antigenic drift when viruses undergo minor mutations each year, such as the influenza A viruses

antigenic shift when viruses undergo a major mutation; has occurred with flu viruses four times over the past 100 years

case definition a set of criteria used to define a disease for the purpose of public health surveillance

case surveillance when public health agencies collect information about an individual diagnosed with a health condition that could potentially pose a health threat to others

emerging infectious diseases (EIDs) diseases that are newly affecting populations or diseases that have existed previously but only caused isolated disease that are now increasing in incidence and geographic range

erythema migrans (EM) also known as the “bull’s eye” rash of Lyme disease; is erythematous, annular, and homogenous at the site of the actual tick bite and expands over several days to sizes greater than 5 centimeters in diameter with a central clearing as the rash expands

infectious easily transmitted between individuals

13.3 Infectious Disease Prevention and Control

Local health care providers, state or local data surveillance, or the CDC’s review of surveillance data and laboratory patterns detect illness clusters to identify outbreaks. Public health surveillance uses data to monitor communicable and noncommunicable diseases, injuries, and risk factors for health outcomes in a population and prevent or control them. Steps in outbreak prevention include preparation; establishing an outbreak’s existence; forming a case definition; finding cases; conducting descriptive epidemiology; developing, evaluating, and refining the hypothesis about the cause; implementing control and prevention measures; maintaining surveillance; and communicating the findings. Nursing’s distinct role in pandemics and outbreaks includes assessment (epidemiological surveillance) and detection (contact tracing). Public health nurses assist with coordinating and implementing local and state disaster plans and participate in the multidisciplinary effort of understanding a health care system’s capacity before a public health emergency strikes.

infectious disease disease caused by pathogenic microorganisms such as bacteria, viruses, parasites, or fungi; enters a human host, multiplies, and causes infection that can spread to others

microcephaly condition where a baby’s head is smaller than expected, impacting brain development

nationally notifiable condition a disease required by law to be reported to government authorities, allowing for case surveillance to assess transmission patterns and determine interventions to control outbreaks

pandemic an epidemic that spreads worldwide

pathogenicity the potential ability to cause disease; the more pathogenic an agent is, the greater the ability it has to cause disease in a susceptible host

public health surveillance the ongoing, systematic collection, analysis, and interpretation of health-related data essential to planning, implementation, and evaluation of public health practice

vectors living organisms, such as ticks and mosquitoes, that can transmit infectious pathogens to humans

Review Questions

1. Public health surveillance can be described primarily as which of the following actions?
 - a. Monitoring occurrences of public health problems
 - b. Developing interventions to control disease outbreaks
 - c. Collecting health-related information from community members
 - d. Tracking individuals who have been exposed to an infectious disease
2. Which factor related to the agent will the nurse include when discussing the epidemiological triad?
 - a. Pathogenicity
 - b. Susceptibility
 - c. Reservoirs
 - d. Environmental changes
3. Which disease does the elementary school nurse identify as being spread via airborne transmission?
 - a. Measles
 - b. Influenza
 - c. Pertussis
 - d. Pneumonia
4. Which of the following factors is a component of the epidemiological triad?
 - a. Susceptibility
 - b. Environment
 - c. Portal of exit
 - d. Pathogenicity
5. The community health nurse is conducting a health screening of an immigrant family. Which finding is an indication of the need for T-Spot testing instead of Mantoux TST testing?
 - a. Prior vaccination with BCG
 - b. Family member who is 10 years of age
 - c. Symptoms of night sweats, fevers, chills, and hemoptysis
 - d. A negative chest X-ray and negative sputum testing for MTB
6. Which primary prevention strategy will the nurse include in a community program on the prevention of hepatitis C?
 - a. Advising individuals with risky sexual behaviors to be screened for hepatitis C
 - b. Stressing that handwashing is important after changing diapers or using the bathroom
 - c. Recommending immunizations against the other viral hepatitis infections
 - d. Instructing individuals to avoid sharing needles, syringes, or other equipment contaminated with blood
7. Which manifestation would the nurse include when teaching about mild to moderate food poisoning at a community health fair?
 - a. Bloody diarrhea
 - b. Diarrhea lasting more than 3 days
 - c. Dehydration
 - d. Fever less than 102°F
8. Which diagnosis would the nurse anticipate when observing a “bull’s eye” rash on a client’s leg?
 - a. Zika virus
 - b. West Nile virus
 - c. Lyme disease
 - d. Dengue fever
9. Which surveillance system would the CDC utilize to track and investigate foodborne illnesses?

- a. System for Enteric Disease Response, Investigation, and Coordination (SEDRIC)
 - b. National Notifiable Disease Surveillance System (NNDSS)
 - c. Global Outbreak Alert and Response Network (GOARN)
 - d. Waterborne Disease and Outbreak Surveillance System (WBDOSS)
- 10.** Which action by the nurse during an infectious disease outbreak is an example of a secondary prevention measure?
- a. Administering immunizations
 - b. Engaging in contact tracing
 - c. Providing direct care to infected individuals
 - d. Educating the public about disease transmission

CHAPTER 14

Environmental Health

FIGURE 14.1 A healthy planet is needed for a healthy environment. (credit: modification of work “Keep My Air Clean” by Kevin Krejci/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 14.1 Understanding Environmental Health
- 14.2 Environmental Exposure and Health Outcomes
- 14.3 Environmental Health Assessment
- 14.4 Climate Change and Population Health
- 14.5 Nursing Practice and Responsibilities in Environmental Health

INTRODUCTION A rural community, nestled against a mountain that was extensively mined and then abandoned, is home to several hundred residents. Most of these residents are retired miners and their families living in older homes that lack adequate ventilation and are often perched next to mounds of mining waste—silent but potentially hazardous reminders of the past. Lately, public health officials have expressed growing concern about severe storms, combined with an eroding landscape, depositing heavy metals into the community’s water supply. Air quality is also compromised, with measurements showing higher than acceptable levels of **particulate matter**, a type of pollution. Despite these issues, emotional bonds to their homes and financial constraints deter the residents from considering relocation. A team of public health nurses specializing in **environmental health** is responsible for assessing the local environment and emerging health crises while respecting the community’s deeply rooted lifestyle and sentiments. Mr. Harper, a retired miner, is among the community members who have been experiencing health concerns in recent years. Later in this chapter you will read about Mr. Harper’s case, how the environment is impacting his health, and how climate change is potentially exacerbating both.

On July 3, 2023, the previous global high temperature record was broken as the Earth’s surface averaged 62.6°F. That record was shattered the following day when the planet reached 62.9°F. Then, on July 6, the record was again

broken with a global average temperature of 63.0°F (Herscher, 2023). These records came on the heels of another record making the headlines: June 2023 was the hottest June worldwide since recording began, with the global surface temperature soaring 1.89°F above the 20th-century average (NOAA National Centers for Environmental Information, 2023). Our planet's environment is changing at a historically unprecedented rate. The impact of this warming on earth's environment—and consequently, human health—cannot be overstated.

The field of environmental health studies the impact of the natural and built environment on human health. As a branch of public health, environmental health aims to prevent or reduce disease, disability, and death by reducing exposure to and risk of hazardous agents, promoting behavioral change, and advancing science and policies. Environmental health brings the importance of public health into focus. Although medical advances are important to individual care, unprecedented gains in public health have doubled life expectancy in the United States since 1880 (Our World in Data, n.d.). These achievements include improved sanitation, nutrition, safe drinking water and food supply, vaccines, and antibiotics. Notably, sanitation, water, and lead poisoning, three of the most significant public health achievements in human history, are integral to environmental health. This chapter provides an overview of environmental health and then discusses nursing practice and responsibilities in relation to it.

14.1 Understanding Environmental Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 14.1.1 Discuss how the environment and human health are linked.
- 14.1.2 Describe the principles and frameworks used in environmental health.
- 14.1.3 Explain Nightingale's environmental theory and its ongoing impact on nursing.

Nearly one-fourth of the worldwide burden of disease could be avoided by creating healthier environments (World Health Organization [WHO], 2023a). The conditions for a healthy environment include clean air, a stable climate, sufficient water, sanitation, safe chemical usage, radiation protection, healthy and safe workplaces, sound agricultural practices, healthy communities and built environments, and preserved nature (WHO, 2023a). Healthy People 2030 includes environmental health, considered a social determinant, as an objective. However, environmental hazards and their impact are not equally distributed, with some communities, such as those with lower-income residents or BIPOC populations, shouldering a disproportionate burden. As discussed in [Structural Racism and Systemic Inequities](#), such communities are more likely to be located in areas with high levels of pollution and hazards, often resulting from discriminatory practices in land use, zoning, and the siting of industrial facilities and waste. Furthermore, these communities may lack or have limited access to resources and political influence to advocate for a healthier environment or mitigate the impact of hazards, leading to an increased risk for numerous adverse health outcomes, including respiratory illnesses, cancer, neurological disorders, and developmental delays.

Nurses are critical for promoting and protecting public health, and knowledge about environmental health is essential to provide optimal, targeted care to populations and individuals. Nurses can identify, prevent, and address environmental health issues, which is particularly important given the increasing impact of environmental hazards on human health.

Linking the Environment and Human Health

Environmental health profoundly influences human health through an intricate relationship and various pathways that shape the well-being of individuals and communities. Industrialized society irresponsibly releases vast amounts of pollutants and toxic waste into the biosphere, alters landscapes, and disrupts global climate, resulting in serious degradation of the Earth's ecosystems. The consequences of such actions eventually impact human populations' health and well-being. Air quality, for example, directly affects respiratory health, with exposure to pollutants such as ozone aggravating respiratory illnesses like asthma and COPD. Similarly, water quality is of paramount importance; contaminated water elevates the risk of ingesting harmful chemicals such as lead or the transmission of waterborne diseases. Food production and nutrition depend on the health of soil, water, and air. Food safety is also dependent on environmental health, as contamination during production, processing, and distribution can lead to outbreaks of foodborne illnesses such as salmonellosis. Waste management and sanitation systems are critical to protecting the environment and our health from contamination and diseases such as cholera (CDC, 2022d). Inequities compound the issue, with vulnerable populations disproportionately bearing the burden of

environmental hazards due to factors such as proximity to industrial sites.

Climate change, discussed in detail in [Environmental Exposure and Health Outcomes](#), introduces another layer of complexity into the relationship between the environment and human health. More frequent extreme weather events amplify risks to both the environment and human health. For instance, extreme heat events exacerbate respiratory and cardiovascular disorders and can lead to wildfires, which further degrade air quality. Warmer temperatures expand the range of disease-carrying vectors, thereby increasing the prevalence of vector-borne diseases such as Lyme disease, caused by Lyme borreliosis carried by ticks and transmitted directly to humans. Environmental disasters can impact our mental health, leading to disorders such as anxiety, PTSD, and depression.

Addressing environmental health requires collaboration among health providers, scientists, engineers, urban planners, public health professionals, organizations and businesses, and agencies across all levels of government. Improving air quality and air quality standards, ensuring the safety and quality of water sources, providing sufficient waste management and sanitation, promoting green spaces, and adopting sustainable practices are required to safeguard both the environment and the health of populations.

NATIONAL CENTER FOR ENVIRONMENTAL HEALTH

[Access multimedia content \(<https://openstax.org/books/population-health/pages/14-1-understanding-environmental-health>\)](https://openstax.org/books/population-health/pages/14-1-understanding-environmental-health)

This video from the Centers for Disease Control and Prevention (CDC) discusses the role the environment plays in maintaining an individual's overall health and well-being.

Watch the video, and then respond to the following questions.

1. What are some of the ways that the National Center for Environmental Health is working to improve public health safety?
2. What are some of the potential health risks associated with environmental exposures?
3. How can nurses address population health challenges associated with environmental factors such as monitoring chemical exposures and preventing childhood lead poisoning?

Frameworks and Principles of Environmental Health

Environmental health aims to prevent illness, death, and disability by reducing exposure to harmful environmental conditions and promoting behavior change. Human behaviors and interactions with the environment have a significant impact on health, including air and water quality, food safety, management of hazardous waste, and efforts to address climate change. Nurses must be equipped to recognize and manage environmental risks that impact their clients and communities, as these risks can significantly affect health outcomes. The section below discusses frameworks and principles to provide guidelines and strategies for addressing environmental health in clients and populations.

HOW DOES ENVIRONMENT AFFECT OUR HEALTH?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/14-1-understanding-environmental-health>\)](https://openstax.org/books/population-health/pages/14-1-understanding-environmental-health)

In this video, Mighty Fine of the American Public Health Association explores how the environment affects our health.

Watch the video, and then respond to the following questions.

1. How did environmental health initiatives in the early 20th century contribute to reducing infectious diseases in the United States? What were some of the key strategies used?
2. The video highlights the concept of environmental justice. How do environmental hazards disproportionately affect BIPOC populations, low-income areas, and underserved groups?
3. How does the involvement of local governments differ from national efforts in promoting environmental health? What challenges might local governments face when implementing initiatives to improve

environmental health within their communities?

Nightingale's Environmental Theory

Florence Nightingale was an early advocate for public health and hygiene, her environmental strategy aimed to improve living conditions and prevent the spread of diseases. Nightingale's **Environmental Theory** viewed nursing as the process of using the client's environment to assist them in their recovery (Gilbert, 2020). Observing that many wounded soldiers were dying from preventable diseases during the Crimean War (1853–1856), Nightingale realized that the unsanitary conditions in military hospitals contributed to the high mortality rate. To address this issue, she developed an environmental strategy that focused on fresh air, clean water, sanitation, hygiene, and light (Gilbert, 2020).

Although less well known as a statistician today, Nightingale was the first woman inducted into the renowned Royal Statistical Society. During the Crimean War, she painstakingly collected and analyzed data on the causes of death and mortality rates of soldiers. To effectively communicate her findings, Nightingale developed innovative visualization methods, including the coxcomb, a graphic representation similar to a pie chart, to demonstrate that a substantial proportion of soldier deaths were due to disease, exposure, and infection rather than injuries from battle and were therefore preventable ([Figure 14.2](#)).

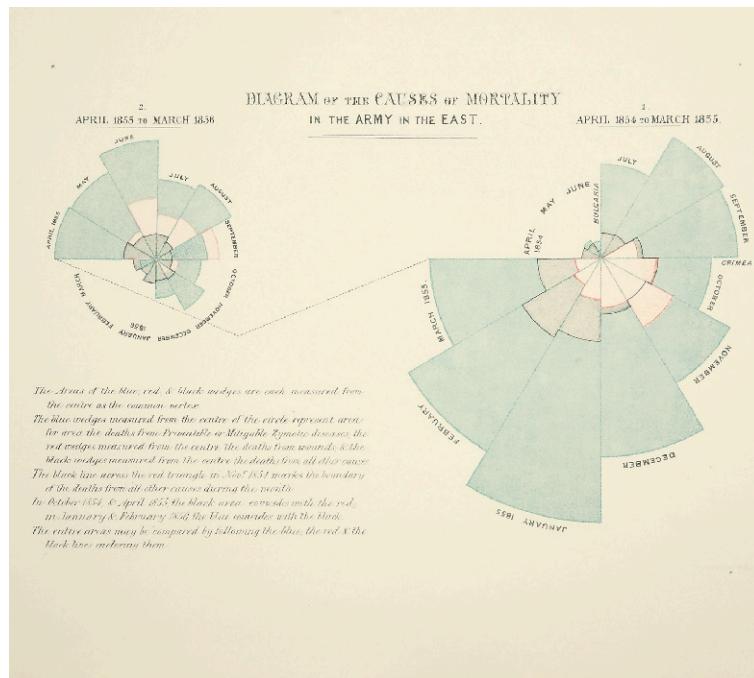

FIGURE 14.2 Florence Nightingale created infographics like this coxcomb to easily communicate complex data. (credit: "Diagram of the causes of mortality in the Army in the East" by National Library of Medicine, Public Domain)

THEORY IN ACTION

What Would Florence Nightingale Make of Big Data?

[Access multimedia content \(<https://openstax.org/books/population-health/pages/14-1-understanding-environmental-health>\)](https://openstax.org/books/population-health/pages/14-1-understanding-environmental-health)

This animation discusses the significance of Nightingale's work on statistics and its lasting impact.

Watch the video, and then respond to the following questions.

- How did Nightingale's background in statistics and her meticulous, data-driven approach impact health care during the Crimean War and after?
- Nightingale's work laid the foundation for modern practices like maintaining cleanliness in health care facilities. In what other ways do you think her principles and methodologies continue to influence modern

- health care?
3. Nightingale's ability to transform data into easily understandable infographics played a significant role in conveying her message to policymakers and the public. How important do you think data visualization is in communicating complex health care information today? How might effective data visualization lead to better health care outcomes?

One Health

The One Health approach (CDC, 2022f) emphasizes the interconnectedness of human health, animal health, and the environment. With growing populations and expanded habitats, closer contact between humans and animals increases disease transmission, while environmental changes and global movements amplify disease spread. These shifts have led to the rise of both known and emerging zoonotic diseases, impacting millions of humans and animals each year. Common One Health issues include emerging zoonotic diseases, antimicrobial resistance, vector-borne diseases, food safety, environmental contamination, and the impacts of climate change. For example, vector-borne diseases such as Lyme, transmitted from ticks to humans, now occur in a wider area as ticks adapt to environmental change. As a result, populations that were previously not at risk of Lyme disease now face increased likelihood of exposure. The CDC uses One Health to monitor and manage public health threats and plan effective public health interventions in collaboration with partners. Ultimately, One Health aims to prevent zoonotic outbreaks, enhance food and water safety and security, mitigate antimicrobial resistance, safeguard global health, and promote biodiversity and conservation. Learn more about One Health in action [here](https://openstax.org/r/cdgovon) (<https://openstax.org/r/cdgovon>).

Upstream vs. Downstream

As introduced in [What Is Population Health?](#), upstream and downstream approaches to health and health care represent different points in the chain of events leading to particular positive or negative health outcomes. Upstream approaches focus on the beginning of the causal pathway by addressing underlying factors, such as the social, economic, and environmental determinants that contribute to health outcomes. Upstream factors are often difficult to see or measure, but they can have a profound impact on human health. For example, programs to reduce poverty or promote sustainable agriculture, campaigns to raise awareness or educate the public on a particular topic, and environmental regulations to reduce pollution are upstream interventions aimed at improving overall health outcomes.

Conversely, downstream factors occur later in the chain of events. These factors are more specific and often relate to individual behaviors and health care delivery systems. Downstream factors are more visible and easier to measure, but they are often the result of upstream factors. Examples of downstream factors in environmental health include individual lifestyle choices and access to medical and preventive care. Interventions using a downstream approach focus on mitigating the immediate effects of health problems, such as screenings, medications, procedures, and individual behavior change programs. While downstream interventions are necessary for treating existing health problems, they often fail to address their root causes and may not lead to long-term improvements in population health. For example, one upstream factor that contributes to air pollution is the burning of fossil fuels, which releases harmful pollutants into the air that cause respiratory problems, heart disease, and cancer. A recent study found that nitrogen oxide, particulate matter, and ozone from U.S. oil and gas production alone resulted in 7,500 additional deaths, 410,000 incidents of asthma attacks, and 2,200 fresh cases of childhood asthma throughout the United States in the year 2016 (Buonocore et al., 2023). An upstream approach would be to control air pollution and reduce exposure. On the other hand, downstream consequences of air pollution include asthma attacks, heart attacks, and premature deaths. Downstream interventions would focus on mitigating the impact of the air pollution by providing treatment for respiratory issues or distributing masks for outdoor use during times when air quality is poor. Addressing upstream factors helps to prevent environmental problems from occurring; addressing downstream factors mitigates the impact of environmental problems.

Environmental Justice

Environmental justice refers to the fair and equitable treatment and meaningful engagement of every individual, irrespective of race, color, national origin, or socioeconomic status, in the development, execution, and enforcement of environmental laws and policies (U.S. Department of Energy, 2023). The goals of environmental justice are to offer equal protection from hazards and to ensure equal involvement of communities in making decisions about policies and regulations that impact them. Advocates of environmental justice aim to ameliorate the

disproportionate burden of environmental hazards encountered by certain marginalized and vulnerable populations (Environmental Protection Agency [EPA], 2023j). Environmental justice connects environmental issues with broader social justice concerns, recognizing that environmental degradation often intersects with issues related to health inequities, housing, education, and economic opportunity. As such, advocates seek to foster sustainable and inclusive communities that prioritize the well-being and health of all residents. They work to raise awareness about these issues, mobilize affected communities, and promote policies and practices that prioritize environmental equity and fairness.

The concept of environmental justice emerged in the 1970s in response to environmental issues often faced by low-income communities, BIPOC communities, and other marginalized groups (Lynch et al., 2021). These communities carry a greater burden, with increased exposure to pollution, toxic substances, hazardous waste, and other environmental hazards due to structural factors such as discriminatory land-use policies, socioeconomic disparities, and lack of political power. Examples of environmental justice issues include siting of polluting industries in low-income neighborhoods, lack of access to clean and safe drinking water in certain communities, and unequal enforcement of environmental regulations. For more on these issues, see [Structural Racism and Systemic Inequities](#).

The movement gained momentum in the 1990s, with the term officially recognized in the Presidential Executive Order 12898 in 1994, directing federal agencies to address environmental justice issues in their programs and policies (EPA, 2023a). In 2021, President Biden issued an executive order to initiate [Justice40](#) (<https://openstax.org/r/whitehouse>), an environmental justice initiative aiming to address environmental and climate issues while prioritizing equity and justice for disadvantaged communities. The initiative, based on the principle that communities that have been disproportionately harmed by pollution and climate change should be first in line to benefit from the transition to a clean energy economy, commits to investing 40 percent of the overall benefits from federal climate and clean energy programs into these communities (EPA, 2023m). Justice40 represents a significant step toward integrating environmental justice principles into federal climate and environmental policies, with a focus on rectifying historical and systemic disparities in environmental protection and climate action (Exec. Order No. 14008, 2021).

Environmental Health Sciences

Exposure assessment, toxicology, epidemiology, and risk assessment are interconnected approaches that play a vital role in the field of public health and environmental health:

Exposure assessment is a subfield that measures, characterizes, and models the frequency, magnitude, and contact duration of agents with an exposed population. Exposure assessments also evaluate the effectiveness of interventions and provide health professionals with information about the source, routes, and areas of uncertainty to help determine a course of action (CDC, 2022b).

Toxicology examines how harmful natural substances (toxins) or harmful artificial substances (toxicants) affect living organisms. The primary goal of toxicology is to assess the potential risks associated with exposure to various chemicals, including drugs, industrial products and by-products, environmental pollutants, pesticides, minerals, and metals. Toxicologists examine how these substances enter the body; how they are distributed, metabolized, and eliminated; and how they affect both organs and systems. The Agency for Toxic Substances and Disease Registry (ATSDR) develops toxicological profiles for hazardous materials, ranked by frequency, toxicity, and likelihood of human exposure. These “Tox Profiles” are extensively researched and peer reviewed. Nurses can access the current list of 275 substances at the [ATSDR’s Substance Priority List](#) (<https://openstax.org/r/atsdr>).

Environmental epidemiology focuses on the links between environmental exposures and human health outcomes. Environmental epidemiologists identify potential environmental health hazards, quantify risk, and explore how different environmental factors, such as air and water pollution, chemicals, radiation, and climate change, impact health. The findings are used to inform public health policy, protect communities from risk, and develop interventions aimed at reducing exposures and improving population health.

Biomonitoring is a scientific methodology used to assess the presence and concentration of specific substances, such as chemicals and pollutants, in living organisms. Samples of blood, urine, saliva, hair, nails, and more may be utilized. Biomonitoring examines the extent of an individual’s or population’s exposure to environmental agents and uses this data to monitor the accumulation and impact of substances over time, identify potential health risks,

inform regulations, and develop targeted interventions. The CDC runs a national biomonitoring program that measures the presence of over 400 chemicals at over 500 laboratories, and the agency has made numerous significant advances in improving population health, including the reduction of exposure to secondhand smoke and lead (CDC, 2022a).

Environmental burden is how public health professionals quantify and compare the impact of environmental risks on a population's health. Climate change, air, noise, and water pollution are examples of environmental burdens because they have detrimental effects on the ecosystem and human health. This burden can manifest in a variety of ways, including increased rates of illness, disability, and premature death as well as decreased quality of life and productivity. Health indicators such as mortality rates, morbidity rates, and disability-adjusted life years (DALYs) are used to measure the impact of environmental hazards on human health and help identify vulnerable populations at risk. Environmental burden considers the **cumulative impacts**, or the total harm to humans resulting from the combination and interaction of multiple factors such as pollution, socioeconomics, and preexisting conditions. For example, the impact of respiratory illness on an individual living in a community with elevated air pollution will be greater than that on an individual living in a community with clean air.

Bioaccumulation refers to the gradual accumulation of contaminants, such as heavy metals like mercury and lead, within the tissues of living organisms. This process occurs as organisms consume contaminants from their surrounding environment more rapidly than they are able to eliminate or metabolize them. Instead of being excreted, the substances become stored in the organism's body, leading to increased concentrations as the toxins accumulate. Over time, organisms higher up the food chain, such as humans, may consume food that contains these accumulated pollutants (EPA, 2021b).

A comprehensive approach is necessary to reduce environmental burden; approaches include addressing the underlying causes of environmental hazards, providing education to the public about hazards, and implementing policies to reduce exposure to environmental pollutants. The C/PHN assesses the reports and then works with regulatory agencies and industries to reduce emissions and waste, advocating for clean energy and transportation and supporting policies that protect vulnerable populations from environmental risks.

CASE REFLECTION

A Home Visit with a Client Who Has COPD

Read the scenario, and then respond to the questions that follow. This case scenario about Mr. Harper will evolve throughout the chapter.

Mr. Harper, a 68-year-old retired miner, has been experiencing increasing difficulty breathing. His health has deteriorated over the past year with two hospitalizations for chronic obstructive pulmonary disease (COPD) exacerbation and recurrent pneumonia. In addition to working in the mines for 44 years, Mr. Harper has a 20-pack/year history of tobacco use and lives alone in an old, damp, poorly ventilated house. His nurse, Regis, is visiting his home for the first time today.

Vital Signs		Physical Examination
Temperature:	99.1	<ul style="list-style-type: none"> HEENT: Within normal limits.
Blood pressure:	150/ 95	<ul style="list-style-type: none"> Cardiovascular: Tachycardic, S1, S2 noted; Regular rhythm; No murmurs or rubs; No jugular vein distention; No edema, 2+ pulses in extremities.
Heart rate:	104	<ul style="list-style-type: none"> Capillary refill > 2 seconds.
Respiratory rate:	26	<ul style="list-style-type: none"> Respiratory: Bilateral rhonchi and wheezing. Productive cough; thick yellow sputum.
Oxygen saturation:	92% on room air	<ul style="list-style-type: none"> GI: Abdomen soft, non-tender, non-distended; bowel sounds normal. GU: Clear urine. Neurological: Presents with occasional confusion. Integumentary: Clean, intact, dry. Complaint of itchiness. Digital clubbing. Cyanosis noted in nail beds.

TABLE 14.1

TABLE 14.1

1. What signs and symptoms of COPD exacerbation and pneumonia does Mr. Harper present with?
2. Identify upstream and downstream factors that could be contributing to Mr. Harper's deteriorating health.
3. What immediate actions should Nurse Regis take while in Mr. Harper's home?

14.2 Environmental Exposure and Health Outcomes

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 14.2.1 Assess environmental hazards and threats to individuals, families, and populations.
- 14.2.2 Examine sources and types of environmental agents and how they affect health.
- 14.2.3 Discuss strategies to reduce environmental risks, exposures, and injury.
- 14.2.4 Explain why individuals, communities, and populations have a right to know about actual or potential environmental risks.

Exposure to hazards in the environment is a growing concern for individuals, families, and populations.

Environmental agents are specific substances that can directly interact with, and potentially impact, the health of the environment and humans. Environmental agents can be categorized into biological, chemical, and physical. The sources of environmental agents are diverse, ranging from human activities to natural disasters and biological events. Environmental agents can create **environmental health hazards**, or conditions that have the potential to cause harm to the environment and humans. The impact of environmental hazards on health can be significant, with potential health outcomes ranging from minor symptoms to severe illnesses and even death. Therefore, it is essential to identify strategies to reduce environmental risks and exposure to injury. Communities and individuals can protect themselves by managing environmental hazards and maintaining safe food and water. Moreover, the right to know about actual or potential environmental risks is crucial for individuals, communities, and populations. This knowledge empowers them to take appropriate actions to protect themselves and their communities.

Environmental Hazards and Impact on Health

Environmental agents have the potential to create hazards by polluting the air we breathe, the water we drink, and the food we eat, affecting our quality of life and overall health. While some of these hazards, such as smoke emanating from stacks, are clearly visible, most are not. For example, small plastic fragments such as microplastics (MPs) and nanoplastics (NPs) are ubiquitous pollutants in water, air, and soil. NPs are more hazardous due to their extremely small size (<1000 nm), which allows them to escape water treatment processes and float long distances in both air and water, contaminating fresh water, oceans, air, and food (Yee et al., 2021). Furthermore, their size enables them to penetrate living tissues and cells more easily. These particles are generated for use in consumer products such as cosmetics, cleansers, and detergents (major sources) and through the degradation of plastics such as tires (Lai et al., 2022). Small plastic contaminants can transport pollutants, microorganisms, and pathogens on their surfaces, which can amplify their physiological and environmental effects (Trevisan et al., 2020). While understanding of the impact of small plastics on human health is only just beginning to emerge, toxicological studies indicate that NPs can cross the blood-brain, intestinal, and placental barriers (Lai et al., 2022).

Human activities are the primary drivers of environmental agents, and societal and lifestyle choices including urbanization, economic activity, recreational pursuits, and food habits play a role. The presence of these agents, or toxins, in the air, water, and land can have deleterious effects on human health across the lifespan. **Teratogens** such as secondhand smoke and alcohol consumption during pregnancy can cause defects in a developing embryo. Alcohol, tobacco, asbestos, and radon are **carcinogens**, or cancer-causing toxins. **Mutagens** such as radioactive substances found in nuclear waste and radon alter a person's DNA. The ingestion or handling of **neurotoxins** such as lead or mercury can lead to adverse effects on the nervous system. Finally, endocrine disruptors such as phthalates and bisphenol A (BPA) are found in many modern consumer products and can have a wide range of effects on the endocrine system, impacting human development and reproduction.

Physical agents include noise, temperature, vibrations, radiation, and lighting, which originate from different sources, including the **built environment** (human-made structures and surroundings) and industry. **Chemical agents** including heavy metals, pesticides, polychlorinated biphenyls (PCBs), chlorofluorocarbons (CFCs), endocrine-disrupting chemicals (EDCs), and sulfur dioxide (SO_2) are used in agriculture, industry, and the burning of

fossil fuels for transportation and electricity. **Biological agents** were the most significant environmental health hazard through much of human history and include molds, dust mites, cockroaches, pollen, bacteria, viruses, protozoa, parasitic worms, and pet dander, saliva, and waste.

Air Pollution

Air pollution is a serious environmental and public health issue that affects people of all ages and backgrounds but most especially the vulnerable, children, older adults, and those with respiratory disorders. Air pollution is caused by the release of harmful substances into the air, such as particulate matter, ozone, and nitrogen dioxide ([Figure 14.3](#)). These substances originate from a variety of sources such as factories, vehicles, and industrial plants. When these harmful substances are released, they mix with the air we breathe, potentially causing a range of health problems if inhaled. For example, particulate matter (PM), a mixture of solid particles and liquid droplets, can penetrate the respiratory system, irritating the lungs and exacerbating health conditions such as asthma and bronchitis. Long-term exposure to particulate matter has been associated with an increased risk of cardiovascular diseases, respiratory illnesses, and even premature death. Ozone, a common pollutant formed when volatile organic compounds (VOC) and nitrogen oxides (NO_x) react to sunlight, can inflame and damage the lining of the lungs, exacerbating respiratory symptoms. Studies have linked ozone exposure to lower birth weights and decreased lung function in newborns, an increased risk of metabolic and cardiovascular disorders, and potentially lung cancer. Nitrogen dioxide (NO₂), produced during fossil fuel combustion, can enter the bloodstream, leading to an inflammatory response such as neuroinflammation; research has linked exposure to NO₂ to an increased risk for neurodegenerative diseases such as Parkinson's (Jo et al., 2021).

The Air Quality Index (AQI) is a system used to communicate information to the public about air pollution levels and any associated health impacts in a specific location. The EPA sets an AQI for five primary air pollutants including ground-level ozone, particulate matter, carbon monoxide (CO), sulfur dioxide (SO₂), and nitrogen dioxide (NO₂). The AQI is divided into six categories, each of which corresponds to a different level of health concern. These categories are color-coded for easy understanding, ranging from Good (Green) for air quality that is satisfactory and poses little or no risk to health to Hazardous (Maroon), which indicates a health warning where the entire population may be affected (Air Now, 2023).

FIGURE 14.3 Factories and industrial plants are one source of air pollution because they release particulate matter, ozone, nitrogen dioxide, and other harmful substances into the air, which mix with the air people breathe and potentially cause a range of health problems if inhaled. (credit: "Cloud factory" by Libelul/Flickr, CC BY 2.0)

Water Pollution

Water, like air, is necessary for life and essential for human health. Water pollution is a serious issue that impacts the health and safety of water bodies, putting both human well-being and the environment at risk. Industrial waste,

agricultural runoff, urbanization, sewage, and oil spills are some of the major contributors to water pollution. Factories release wastewater containing harmful chemicals and heavy metal into our waterways. Farms contribute to water pollution when fertilizers and pesticides wash into waterways, referred to as runoff. Agricultural runoff can have a devastating impact on water quality and the creatures that live in our waterways. Excess nutrients from fertilizers can lead to algal blooms, which choke the life out of aquatic ecosystems and create dead zones. Pesticides and herbicides used to protect crops can harm aquatic life. Prolonged exposure to pollutants like lead, arsenic, and mercury can have severe health implications, especially when they build up in the human body.

Lead, a toxic metal, poses a significant threat, even at low levels. Its persistence in the environment allows it to linger for extended periods. Rain from urban areas runs into storm drains, bringing pollutants from streets, parking lots, and roads into nearby streams and rivers. Oil spills can travel a significant distance, polluting a large area and devastating marine life. Drinking water can be a particular concern if contaminated with lead from sources such as lead pipes or plumbing fixtures; additionally, soil and groundwater contamination can also contribute to lead in drinking water. Lead exposure may lead to severe health problems, including developmental disabilities, learning disabilities, neurological damage, premature birth, low birth weight, seizures, and hearing loss (CDC, 2022d). Children are particularly vulnerable to the effects of lead poisoning; even at low levels, lead exposure can have far-reaching consequences to their health. Recognizing the dangers posed by lead, the Environmental Protection Agency (EPA) established a maximum contaminant level goal (MCLG) of zero for lead in drinking water (EPA, 2023a), meaning that the EPA considers any level of lead in drinking water to be unsafe.

Perfluoroalkyl and polyfluoroalkyl substances (PFAS), also known as “forever chemicals,” are synthetic compounds characterized by a strong carbon-fluorine bond. This unique bond gives PFAS the ability to withstand heat and repel water and fats, leading to their extensive use in various manufacturing industries and consumer goods for more than 70 years (Wylie & Malits, 2022). PFAS are found in nonstick cookware, stain-resistant fabrics, fast-food packaging, personal care products, and more. Due to their resistance to breakdown, PFAS persist in the environment, contaminating water, air, and soil. Furthermore, PFAS are not easily metabolized and can remain in the body for years or even decades (Wylie & Malits, 2022). Due to the persistent nature of PFAS in the environment and their common routes of exposure through drinking and eating, nearly everyone has measurable levels of PFAS in their blood. Individuals working in occupations related to PFAS manufacturing and firefighters might experience higher exposure levels. Infants can also be exposed through transplacental transmission during pregnancy or through breast milk. PFAS exposure has been associated with various health effects, including obesity, elevated cholesterol, cancers, thyroid problems, colitis, learning difficulties, delayed puberty, and adverse pregnancy outcomes (Wylie & Malits, 2022). For example, a study of more than 10,000 individuals showed that those with higher PFAS exposure had a 40 percent greater likelihood of developing preeclampsia than those with lower exposures (Braun, 2023). The EPA proposed national standards in March 2023 to address concerns about PFAS in public drinking water supplies. The proposed standards aim to limit concentrations of six PFAS compounds in drinking water (Braun, 2023).

Finally, water pollution also affects human health indirectly by degrading the ecosystem. Polluted water harms aquatic life, disrupts food chains, and causes declines in fish populations that communities depend on for sustenance and livelihoods. The impact of water pollution is wide-ranging and can profoundly affect human health as well as that of the environment.

THE ROOTS OF HEALTH INEQUITIES

PFAS Contamination in Disadvantaged Communities

A recent report from the Government Accountability Office (GAO) examined the presence of PFAS in the drinking water systems of several states, including Illinois, Massachusetts, New Hampshire, New Jersey, Ohio, and Vermont. The overall findings indicated that out of the 5,300 water systems analyzed, approximately 29 percent of the population served by these systems had drinking water with PFAS levels that exceeded the safety standards set by the EPA (U. S. Government Accountability Office, 2022).

The authorities then investigated potential disparities related to PFAS contamination, focusing on large community water systems. The results showed that disadvantaged communities in New Jersey were more likely to have PFAS-contaminated drinking water compared to other communities (Suran, 2022).

CLIENT TEACHING GUIDELINES

Reducing PFAS Exposure

Nurses can educate clients on the following measures to reduce PFAS exposure:

- Replace old, chipped, or damaged nonstick cookware. When using nonstick cookware, use a low to medium heat setting.
- Limit intake of fast food, which often comes in PFAS-coated packaging.
- When possible, use filters that remove PFAS from drinking water.
- Vacuum frequently, especially for older carpeting.
- Limit intake of microwave food such as popcorn and foods in microwavable packaging.

Land Pollution

Soil pollution is a serious problem with potentially devastating consequences for both the environment and human health. It occurs when harmful substances contaminate soil through industrial processes, agricultural practices, improper waste disposal, and the use of hazardous chemicals. Common soil pollutants include heavy metals such as lead, mercury, cadmium, and arsenic as well as pesticides, herbicides, industrial chemicals, and petroleum products. These substances can persist in the soil for an extended period, making the problem long-lasting and challenging to remediate. For instance, improper waste disposal is a significant contributor to land pollution. When non-biodegradable waste materials like plastics are deposited in landfills or open areas without proper management, they can release toxic chemicals and contaminants into the soil. Industrial activities are another major cause of land pollution. Factories and manufacturing plants often release hazardous substances directly into the soil or air. Agricultural practices, while essential for food production, can also contribute to soil pollution. Chemical fertilizers, pesticides, and herbicides can accumulate in the soil, negatively impacting soil fertility and potentially seeping into water sources. Urbanization and construction projects further exacerbate land pollution. The clearing of land for buildings, roads, and infrastructure can cause soil erosion, deforestation, and habitat loss, disrupting the ecosystem's equilibrium. The consequences of land pollution are extensive. Contaminated soil can negatively affect plant growth, reduce agricultural yields, and harm wildlife, leading to a decline in biodiversity. For humans, polluted soil poses significant health risks in several ways. Crops grown in polluted soil can absorb toxins, contaminating food and potentially impacting health. Contaminated soil may release harmful substances such as particulate matter into the air or nearby water bodies, further spreading pollution and significantly impacting air quality and water safety.

Due to the dangers posed by contamination, the EPA administers programs to identify, evaluate, and potentially redevelop polluted sites. The Superfund program is a federal government initiative overseen and managed by the EPA. Superfund sites are locations where substantial hazardous substances have been released into the environment, posing risks to human health and the ecosystem. These sites are regulated by the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), commonly known as Superfund (EPA, 2023n), which provides the legal framework for the cleanup and remediation. The program aims to identify, prioritize, and assess sites as well as facilitate decontamination, often a multiphase process involving federal and state agencies, responsible parties, and the affected community. You can search for superfund sites in your community and elsewhere [here \(<https://openstax.org/r/epagov>\)](https://openstax.org/r/epagov). The EPA also administers a Brownfields program (EPA, 2023l). Brownfields are properties that are, or are suspected to be, contaminated by industrial or commercial activity. Caused by pollution from former businesses such as factories, gas stations, dry cleaners, landfills, and manufacturing facilities, brownfields may have hazardous agents in the soil, groundwater, or structures, posing a risk to both environmental and human health. Unlike Superfund sites, brownfields may not contain severe levels of contamination requiring immediate federal intervention but instead have potential for redevelopment or revitalization. The EPA estimates that there are approximately 450,000 brownfields sites in the United States.

Strategies to Reduce Risk

The Right to Know principle supports access to information held by public organizations and is based on the idea that transparency, openness, and accountability are critical to a healthy society and the protection of human rights. In 1986, the Emergency Planning and Community Right-to-Know Act (EPCRA) was passed to address concerns

about the safety and environmental hazards associated with the storage and handling of toxic chemicals. Concerns were sparked by the 1984 Bhopal disaster, in which an extremely toxic pesticide, methylisocyanate, leaked in the middle of the night into the city of Bhopal, India, killing and severely injuring thousands (Chatterjee, 2023). To reduce the likelihood of such a disaster in the United States, Congress imposed certain requirements for emergency planning and reporting of hazards and toxins. The provisions of the Community Right-to-Know initiative serve to enhance the public's awareness of, and access to, information on the presence, application, and release of chemicals at certain facilities. In 2018, the reporting requirements of EPCRA were revised by the America's Water Infrastructure Act (AWIA) to provide for notification of state agencies with data on reportable releases of chemicals into water sources (EPA, 2023a).

Reducing the risk of land, air, and water pollution begins with reducing hazardous agents and requires serious commitment on the part of individuals, businesses, communities, regulatory agencies, and governing bodies. Some general strategies include the following:

- Regulation and monitoring to ensure safety and compliance
- Legislation and enforcement to hold polluters accountable
- Incentives for businesses, communities, and individuals to adopt environmentally friendly practices
- Conversion to renewable sources of energy
- Investment in research and development of innovative technologies
- Raising awareness about the effects of the environmental hazards on health
- Reduce, reuse, recycle!

[Table 14.2](#) presents community-level strategies to reduce the risk of land, air, and water pollution.

Type of Pollution	Strategies to Reduce Risk
Soil and land	<ul style="list-style-type: none"> • Proper waste management, including the safe disposal of hazardous materials • Contaminated site remediation and brownfield redevelopment, which may include chemical treatment and soil excavation • Sustainable agriculture and land use, including the adoption of farming practices that reduce reliance on harmful pesticides and fertilizers • Promoting green technologies such as bioremediation, which uses living organisms such as bacteria and fungi to naturally break down pollutants, or the use of green roofs
Air	<ul style="list-style-type: none"> • Policies that promote cleaner and renewable sources of energy, such as solar power • Regulation and reduction of emissions by industries, vehicles, and power plants • Updated, reliable systems of public transportation • Improved infrastructure for walking and cycling to reduce vehicle use • Air quality monitoring and alerts for unhealthy air • Reforestation and the development of urban green spaces to absorb pollutants and improve air quality
Water	<ul style="list-style-type: none"> • Protection of water sources from contamination through appropriate land use and water quality monitoring • Wastewater treatment and management, including upgraded facilities to ensure effective removal of hazardous agents • Stormwater management through retention ponds, rain gardens, and permeable pavement • Educate the community about proper disposal of hazardous materials that can enter the waterways, such as chemicals and medications

TABLE 14.2 Community-Level Strategies to Mitigate Soil, Air, and Water Pollution

CLIENT TEACHING GUIDELINES

Strategies for Reducing Risk and Improving Environmental Health

While the strategies in [Table 14.2](#) are effective at the community level, individuals also play an important role in protecting the environment and their health. However, they are often unsure of what they can do to reduce their footprint and live more healthfully in the environment. Nurses can provide clients with the following individual strategies to reduce risk and improve environmental health:

- Compost organic matter to reduce improve soil quality and health
- Dispose of waste, including hazardous materials, medications, and electronics, according to local regulations
- Minimize the use of pesticides, herbicides, and fertilizers
- Purchase food from reputable sources and consider, if possible, organic options
- Support local cleanup and outreach efforts
- Limit use of plastics, especially those that are single use
- Ensure drinking water is from a safe and reliable source
- Avoid swimming or using water that appears polluted or is known to be polluted
- Avoid outdoor activities when air quality is poor
- Use rainwater harvesting, the collection of rainwater to reuse for non-drinking purposes
- Use public transportation, walk, or bicycle
- Reduce contaminants in the home through regular cleaning and maintenance
- Ensure the home is properly ventilated and reduce indoor pollutants such as tobacco smoke
- Use energy-efficient appliances when available
- Maintain personal vehicles to regulatory standards
- Advocate for policies that invest in, develop, and support green practices

14.3 Environmental Health Assessment

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 14.3.1 Discuss the methods of measuring pollutants in the environment.
- 14.3.2 Explain the steps in the risk assessment and risk-management processes.
- 14.3.3 Assess the environmental health of individuals, homes, and communities.

Environmental assessment is the process of identifying, evaluating, and mitigating environmental risks to human health. It involves measuring pollutants, determining and managing risks, and conducting individual, home, and community assessments.

Measuring Pollutants

Measuring pollutants is essential for assessing and managing environmental and public health risks ([Figure 14.4](#)) (Manosalidis et al., 2020). Accurate measurement helps identify sources of pollution, monitor trends, and guide regulatory action. While environmental scientists are responsible for measuring pollutants, the C/PHN's role is to ensure that measurements are taken, the results are communicated to the public, and any issues of concern are followed up on. The first step in measuring pollutants involves collecting samples. Different collection methods are used depending on the type of pollutant and the medium in which it is present (air, water, soil, etc.). Sampling may involve placing sensors, samplers, or collection devices in the target environment. Once samples are collected, various analytical techniques such as spectroscopy are deployed to determine the concentration of specific pollutants. For air pollutants, monitoring stations are set up in various locations to measure the concentration of gases and particulate matter. Instruments like gas analyzers, particle counters, and meteorological sensors help assess the levels of pollutants such as carbon monoxide, sulfur dioxide, nitrogen oxides, ozone, and particulate matter. Water pollutants are measured with optical sensors, ion-selective electrodes, and spectroscopy to determine the presence and concentration of contaminants like heavy metals and chemicals. Soil is assessed using chemical and spectral analysis, with samples collected from different depths to understand the distribution of pollutants in the land.

FIGURE 14.4 A team takes stream water samples in Los Padres National Forest in California. (credit: “Habitat Assessment” by Hazel Rodriguez/USFWS/Flickr, Public Domain)

Pollutants may also be measured indirectly through remote sensing techniques such as satellite imagery and aerial photography, which can be used to monitor larger areas and track pollution trends over time. These methods are also very useful for gauging changes in land use, deforestation, erosion, climate change, and other environmental factors that can contribute to pollution. Finally, climate modeling is used to predict and assess the impact of climate change, such as an increase in extreme weather that may lead to an increase in heat-related mortality.

In addition to providing data to assess and monitor the health of a population, measurements of hazardous agents play a significant role in protecting the community by supplying evidence for developing and enforcing environmental regulations.

Determining Risk and Risk Management

The EPA uses a four-step risk assessment to evaluate potential pollution and hazards, evaluate the likelihood of exposure-related health threats, and develop standards (EPA, 2023k). The first step, Hazard Identification, aims to identify potential negative outcomes that may result due to exposure to a specific agent. While multiple data points are involved in this analysis, the emphasis is on **toxicokinetics**, or the study of how chemicals are absorbed, metabolized, and eliminated, and **toxicodynamics**, which examines the impact of chemicals on the body and health.

The second step, Dose Response, aims to identify the ways that the amount of exposure (dose) relates to the probability and severity of negative health effects (response). The third step, Exposure Assessment, involves quantifying the extent, frequency, and length of human contact to an environmental agent or predicting the potential impact of future contact. Finally, Risk Characterization, the fourth step, aims to synthesize information from the first three steps to provide an overall understanding of the characteristics and occurrence of risks as well as indicate where uncertainties remain.

When the available evidence is uncertain or incomplete, a guiding concept is the **precautionary principle**, which directs decision makers to be proactive in safeguarding the environment and public health rather than waiting for conclusive evidence of harm. This principle shifts the burden of proof, or responsibility, to those advocating for a particular action, such as building a new power plant, to demonstrate that it will not cause harm to the environment or community. The principle can also lead to taking action to prevent harm, such as the decisions made by various governments at the start of the COVID-19 pandemic to institute public health measures such as mask wearing, lockdowns, and travel restrictions, among others. Since little was known about this novel coronavirus, early action without scientific certainty was deemed necessary to protect the health of the public. This is an example of the

precautionary principle in action.

Environmental Health Assessments

The link between human health and the environment underscores the need for systematic evaluations, which play a critical role in understanding population health. This section examines how environmental assessments inform nurses about the impact of the environment on the health of communities as well as individuals.

Individual Assessment

Individual environmental health assessments are essential tools for identifying, preventing, and educating individuals about environmental health concerns. These assessments aim to identify hazards, understand health implications, and mitigate risks. Individual environmental health assessments encompass a broad range of potential environmental exposures, including indoor agents, outdoor air pollution, water sources, exposure to pesticides or industrial waste, and the presence of radiation sources like radon. Factors such as the home and school or work environments, recreational activities, lifestyle, and personal health history are all considered. These assessments empower individuals to make informed decisions and assist nurses with individualizing care, creating action plans, and providing education, referrals, advocacy and follow-up.

In 2005, a team of nurses devised a framework, termed I PREPARE, as a tool for conducting individual environmental health assessments and developing a plan of action. I PREPARE is a mnemonic; each letter stands for a specific step in the assessment (Paranzino et al., 2005) as shown in [Table 14.3](#). The Case Reflection that follows walks through an example of a nurse using I PREPARE to perform an individual environmental health assessment.

Explanation	Examples of Nursing Actions
I Investigate potential exposures: This step involves asking questions to uncover potential sources of exposure to environmental hazards.	Ask if a client has ever felt sick after handling chemicals or toxic substances.
P Present work: Inquire about the person's current occupation and any potential workplace hazards.	Ask the client to describe their current job, the industry they work in, and any hazardous substances that they handle.
R Residence: Assess potential residential exposures.	Ask about the age and type of dwelling, their water source, and indoor hazards such as mold or mildew.
E Environmental concerns: Encourage clients to discuss environmental concerns in their neighborhood.	Ask if they live near landfills, farms, or factories.
P Past work: Inquire about past occupations or exposures that may have exposed the client to hazardous materials in the past.	Ask if they have ever worked on a farm or in a factory or used solvents or other chemicals.
A Activities: Assess the client's activities that may have exposed them to environmental hazards.	Ask about hobbies, outdoor recreation, smoking, and diet.
R Referrals and Resources: Provide information about relevant resources, referrals, or organizations that can help the individual address their environmental health concerns.	Provide information on government sites, such as the CDC, Agency for Toxic Substances & Disease Registry, or the Occupational Safety & Health Administration.
E Educate: Share information about the client's potential environmental health risks and provide guidance on how to prevent or reduce exposure to protect their health.	If they may have been exposed to lead in their drinking water, provide information about testing and mitigation from local, state, and federal resources.

TABLE 14.3 The I PREPARE Mnemonic

CASE REFLECTION

Performing an Individual Environmental Health Assessment

Read the scenario, and then respond to the questions that follow.

Kyra, a 35-year-old client, presents to the county clinic after experiencing persistent symptoms, including coughing, sneezing, and hoarseness, for several months. She's concerned that her symptoms might be related to the apartment she recently moved into. After reviewing her health history, Nurse Kyle uses the I PREPARE framework to perform an individual environmental health assessment.

I—Investigate Potential Exposures: Kyle asks Kyra if she has had any known exposure to pollutants at home, at work, or in the community. He asks if her symptoms improve or worsen when she is at home, at work, or outside. Kyra notes while she isn't sure what she's being exposed to, she usually feels worse in the morning.

P—Present Work: Kyle asks about Kyra's work environment. Kyra is a graphic designer who works 3 days a week in a well-ventilated office building downtown and works from home the remaining 2 days.

R—Residence: Kyle investigates potential exposures by asking about the age and upkeep of the apartment building, such as whether it's properly ventilated, if there have been any water leaks or mold issues, and if there are any pets or smokers in the home. She lives with her cat Mittens in an interior apartment on the first floor of an older building without air conditioning, but she does have a window in her kitchen. Kyra notes that the basement is used for utilities, such as laundry, and is poorly lit, unventilated, and damp.

E—Environmental Concerns: Kyle asks about industries, farms, and waste sites near Kyra's home or workplace. She states that there has been ongoing construction adjacent to her building that often creates a layer of dust and construction debris in the immediate surroundings.

P—Past Work: As a junior designer, Kyra worked for a small business in an old industrial warehouse. She doesn't know much about the history but states that they were not allowed to drink from the building's faucets and were directed to use the water cooler.

A—Activities: Kyra enjoys gardening on her small balcony but finds it increasingly challenging due to her symptoms, which she says worsen when the nearby construction is underway.

R—Referrals and Resources: As a nurse working in a community clinic, Kyle is well prepared to offer referrals and local resources. After confirming Kyra's insurance, he provides contact information for an allergy center covered by her plan and refers her for allergy testing.

E—Educate: Kyle works with Kyra to educate her about indoor and outdoor air quality, potential allergens, and actions she can take to make her environment and lifestyle healthier for now and the future.

1. If you were Nurse Kyle, what additional questions would you ask Kyra to further investigate her symptoms and potential sources of exposure?
2. From an environmental health perspective, what are some possible indoor environmental hazards that could be linked to Kyra's health issues? What about outdoors? How can these be mitigated?
3. Given Kyra's past work history in the warehouse and the directive to avoid tap water, what are some potential concerns in the warehouse space?
4. How might Kyra's gardening activity on her patio interact with the nearby construction? How might Kyra's activities be adapted to minimize her exposure to allergens and irritants?
5. What education should Nurse Kyle provide? What role does education play in preventing environmental health concerns such as Kyra's? How might this knowledge empower her to take proactive steps to improve her environment and overall health?

Home Assessment

What constitutes an environmentally healthy home? According to the National Center for Healthy Housing, a healthy home is dry, clean, safe, ventilated, pest and contaminant free, regularly maintained, and has a comfortable temperature (National Center for Healthy Housing, 2023). Home health assessments are critical for promoting

health equity by addressing disparities in housing quality. For example, programs to improve home indoor air quality are proven to reduce the incidence of asthma among BIPOC children and children residing in substandard housing (Martin et al., 2021). Furthermore, this intervention can improve the health of older adults with respiratory diseases.

Some individuals are more vulnerable to the effects of an environmentally unhealthy or unsafe home. Children, whose bodies and systems are still developing, are particularly prone to negative impacts from exposure to contaminants. Older adults, who may have preexisting health conditions, may have weaker immune systems, and may spend more time indoors, can be more susceptible to respiratory and other disorders. Pregnant people can be exposed to indoor pollutants that affect fetal development, such as secondhand smoke. Individuals with chronic conditions, such as immune or respiratory disorders, are at a higher risk of exacerbations. Individuals with limited mobility due to disability, age, or aging may spend more time indoors and have difficulty relocating to a safer environment. [Table 14.4](#) presents some examples of possible hazards inside the home.

Type of Hazard	Potential Negative Health Effects
Biological Hazards	
Mold and fungi	<ul style="list-style-type: none"> Produce compounds such as aldehydes Can cause a stuffy nose, sore throat, coughing or wheezing, burning eyes, or skin rash Can exacerbate asthma or cause severe allergic reactions May cause lung infections in those who are immunocompromised or have chronic lung disease
Rodents (rats, mice)	<ul style="list-style-type: none"> May cause and contribute to respiratory illnesses Carry many diseases that can spread to people directly through contact with feces through handling or inhaling Carry ticks, mites, or fleas that can act as vectors to spread diseases between rodents and people
Dust mites and cockroaches	<ul style="list-style-type: none"> May cause runny nose, watery eyes, sneezing, cough, congestion, and facial pressure Increased risk of asthma attacks in those who have asthma
Toxic Gases	
Radon	<ul style="list-style-type: none"> Linked to increased cancer risk, poses a significant health threat in some areas where it is commonly found in basements
Carbon monoxide	<ul style="list-style-type: none"> Binds to hemoglobin when inhaled, reduces the carrying capacity of oxygen, and can rapidly lead to severe outcomes including mental confusion, loss of consciousness, hypoxia, and death
Tobacco smoke	<ul style="list-style-type: none"> May damage the heart and blood vessels and cause coronary heart disease, stroke, and lung cancer Pregnant persons exposed to secondhand smoke during pregnancy are more likely to have newborns with lower birth weight. Newborns exposed to secondhand tobacco smoke are more likely to die from sudden infant death syndrome (SIDS) than infants who are not exposed. Causes increased risk for acute respiratory infections, middle ear disease, more frequent and severe asthma, respiratory symptoms, and slowed lung growth and can trigger asthma attacks in children
Toxic Substances	

TABLE 14.4 Examples of Possible In-Home Health Hazards (See American Lung Association, 2023a, 2023b; CDC, 2022e; CDC, 2023; EPA, 2022a; U.S. Consumer Product Safety Commission, n.d.)

Type of Hazard	Potential Negative Health Effects
Asbestos	<ul style="list-style-type: none"> When inhaled, asbestos fibers cause increased risk of lung cancer, mesothelioma, and asbestosis.
Lead	<ul style="list-style-type: none"> When ingested through water or peeling paint in older homes, lead exposure can lead to developmental delays and intellectual disabilities, behavioral problems, and stunted growth.
Pesticides	<ul style="list-style-type: none"> Exposure may cause eye, nose, and throat irritation; damage to central nervous system and kidneys; and an increased risk of cancer. Chronic exposure may damage the liver, kidneys, and endocrine and nervous systems.

TABLE 14.4 Examples of Possible In-Home Health Hazards (See American Lung Association, 2023a, 2023b; CDC, 2022e; CDC, 2023; EPA, 2022a; U.S. Consumer Product Safety Commission, n.d.)

Due to the disproportionate impact of the home environment on children, it's especially important for nurses to incorporate home environmental assessments when caring for the pediatric population. The [Pediatric Environmental Home Assessment](https://openstax.org/r/hudgov) (<https://openstax.org/r/hudgov>) is an excellent tool for assessing the pediatric home environment, with a section for nursing observations. The [National Center for Healthy Housing](https://openstax.org/r/nchhorg) (<https://openstax.org/r/nchhorg>) provides numerous interventions and resources focused on safe and healthy housing for all, especially the millions of Americans living in substandard housing. The passage of the Inflation Reduction Act in 2023 included substantial funding to improve efficiency and resilience in affordable housing and significant funding for research, development, and implementation (Goodwin & Jacobs, 2022).

Community Assessment

Community health assessments provide information about the potential, and real, environmental risks faced by individuals living, working, or recreating in a particular community. The assessment should include environmental health risks using online tools to identify potential exposures and types and levels of pollution using [Envirofacts](https://openstax.org/r/enviroepa) (<https://openstax.org/r/enviroepa>). While this data is critical, it is only part of the community assessment. Nurses can conduct a windshield survey to visually identify potential environmental risks, such as the location of industries, hazardous waste, dumps, major thoroughfares, pests, the use of pesticides, air quality, and housing conditions (see [Creating a Healthy Community](#) and [Appendix A](#)). In addition to observing environmental risks, a windshield survey should note areas that promote health in the community, such as parks, open spaces, gardens, and outdoor recreational areas. The University of Maryland School of Nursing and Environmental Health Center has developed the following [Environmental Health Community Assessment tool](https://openstax.org/r/envirnorg) (<https://openstax.org/r/envirnorg>) focused on environmental health.

CASE REFLECTION

Performing Home and Community Health Assessments

This scenario continues to follow Mr. Harper from earlier in this chapter. Read the scenario, and then respond to the questions that follow.

While assessing Mr. Harper's home environment, Nurse Regis discovers that the house is adjacent to a mound of mining waste, raising concerns about the possible inhalation of particulate matter. Moreover, after hearing rumors that the community's water supply might be contaminated, Mr. Harper now uses water hauled by his neighbor from a nearby stream. Mr. Harper points out the stream to Nurse Regis, who notes that rocks are tinged with red, a sign of acid mine drainage. Upon further assessment, Nurse Regis finds that Mr. Harper's skin is reddened, dry, and itchy. When asked about the rash, Mr. Harper becomes irritable, stating he isn't sure when the rash began and is more upset that he's recently been having difficulty remembering things and easily becomes confused.

The nurse collaborates with a social worker from the county's department of aging to arrange for an aide to assist Mr. Harper twice weekly, helping to keep his home dry and free of dust and bringing him a supply of bottled water to use until the community's water is verified as safe.

1. What further assessments should the nurse conduct given the suspicion of hazardous exposures?
 2. How should the nurse address Mr. Harper's exposure to heavy metals in his daily life?
 3. As a public health nurse, what immediate actions would you take for Mr. Harper and his community? What resources would you use?
-

14.4 Climate Change and Population Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 14.4.1 Examine the impact of climate change on environmental and human health.
- 14.4.2 Identify strategies that aid in reducing the threats of climate change.
- 14.4.3 Define green and sustainable development and its implications for improving health outcomes.

On July 27, 2023, UN Secretary-General Antonio Guterras warned that “the era of global warming has ended, the era of global boiling has arrived. The air is unbreathable. The heat is unbearable. And the level of fossil fuel profits and climate inaction is unacceptable” (Guterras, 2023). July 2023 was likely the hottest month ever recorded in Earth’s history (National Oceanic and Atmospheric Administration [NOAA], 2023a).

As noted at the beginning of the chapter, our planet is rapidly warming. Data indicate that since the pre-industrial era (1880–1900), the earth’s average temperature has risen at least 1.1°Celsius (2.3°Fahrenheit), an extremely rapid rate of warming not previously seen during the entire existence of humanity (National Aeronautics and Space Administration, 2023). Most of this warming has occurred since 1975 (National Aeronautics and Space Administration, 2020). **Climate change** refers to profound and lasting shifts in Earth’s climate patterns and conditions. It is an urgent issue with significant implications for both the environment and human health. The severity of climate change and associated extreme weather events have a substantial impact on the environment, including changes in weather patterns, rising sea levels, and loss of biodiversity. These changes also affect human health, morbidity, and mortality.

The warming of the Earth over the past century is undeniable. Extensive observations of air and ocean temperatures, sea levels, and snow and ice patterns confirm these shifts as unparalleled. Human activity is known to be the primary cause of this warming. While natural processes have historically shaped the planet’s climate, the term *climate change* refers to the significant and rapid alterations occurring since the mid-20th century and largely attributed to human activities. The main driver of climate change is the escalating concentration of greenhouse gases in the atmosphere from human industrialization. Greenhouse gases, including carbon dioxide (CO₂) released through the burning of fossil fuels, methane (CH₄) released from livestock and landfills, nitrous oxide (N₂O) released from agriculture and industry, and chlorofluorocarbons (CFCs) used in industrial applications, contribute to the greenhouse effect by trapping heat in Earth’s atmosphere, preventing it from escaping into space and causing temperatures to rise. The increase is attributed to human actions (EPA, 2023e). Data indicate that present global atmospheric carbon dioxide levels are unparalleled in the context of the past 800,000 years, even when accounting for natural fluctuations. Methane concentrations have more than doubled since pre-industrial times, and levels of N₂O reached an all-time high in 2021 (EPA, 2023c).

Between 1990 and 2019, the cumulative warming impact of human-generated greenhouse gases in Earth’s atmosphere surged by 45 percent (Romanello et al., 2022). Notably, warming attributed just to CO₂ increased by 36 percent during this period ([Figure 14.5](#)). The largest source of emissions worldwide is transportation, followed by generation of electricity (EPA, 2023e). Pervasive and rapid shifts in the atmosphere, oceans, and biosphere will continue and likely worsen. Yet global greenhouse gas emissions continue to climb, reaching record levels (World Meteorological Organization, 2023) from unsustainable energy consumption, land use changes, lifestyles, and consumption patterns across regions, nations, and individuals. At the same time, oil and gas companies make record profits while their production strategies continue to harm the environment. A recent analysis of the production strategies of national oil and gas companies indicated that they would exceed their emissions allotment by 37 percent in 2030 and 111 percent in 2040 (Romanello et al., 2022), undermining efforts to create a sustainable future that prioritizes planetary and human health. The health care sector is the second largest polluter of greenhouse gas emissions in the United States, accounting for 8.5 percent of all emissions and 7 percent of CO₂ emissions. The U.S. health care system generates approximately 25 percent of all global emissions (Wade, 2023).

CARBON DIOXIDE OVER 800,000 YEARS

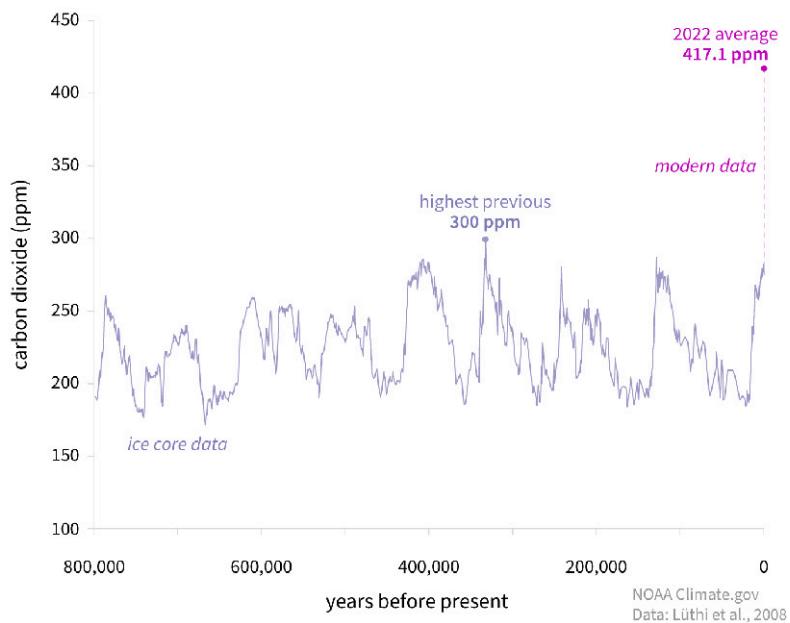

FIGURE 14.5 Atmospheric carbon dioxide has spiked over the last 800,000 years. (credit: “Carbon Dioxide Over 800,000 Years” by NOAA National Centers for Environmental Information, Public Domain)

Due to the extent of human-generated, irreversible change, our current geological time period is now referred to as the **Anthropocene**. The Anthropocene is already influencing weather and climate patterns and extremes worldwide.

The Impact of Climate Change

The impact of climate change has far-reaching consequences, many of which are not yet fully understood or known. Climate change is a global concern that affects multiple aspects of the environment, including air and water quality, land use and the food system, biodiversity, the health of ecosystems, alterations in the distribution and behaviors of plant and animal species, and the spread of infectious diseases. Urgent action is needed to mitigate the effects of climate change, as failure to respond will be costly in terms of disease, health care expenditure, and lost productivity (WHO, 2023b). Climate and ecological change impacts represent the greatest global health challenge, and society must be prepared to face the associated risks and challenges.

Oceanic Impact

Encompassing approximately 70 percent of the Earth’s surface, oceans are vital to planetary health. Oceans absorb both carbon dioxide (CO_2) and heat, slowing the progression of atmospheric global warming. However, this absorption transforms the ocean’s chemistry and temperature, leading to ocean acidification and sea level rise, shifting currents, and impacting marine life and biodiversity (EPA, 2023h). The oceans have absorbed about 28 percent of annual anthropogenic CO_2 emissions and captured approximately 90 percent of the planet’s heat generated by greenhouse gases (EPA, 2023i). As a buffer, the oceans have offset climate impacts. However, as the ocean’s acidity and temperatures rise, its capacity to absorb CO_2 from the atmosphere diminishes, potentially hampering its ability to moderate climate change. Furthermore, the increased absorption of heat leads to higher sea surface temperatures and sea levels (EPA, 2023i). Climate change-induced shifts in ocean temperatures and currents are altering global climate patterns. For instance, warmer waters fuel stronger tropical storms, resulting in flooding, property damage, environmental devastation, and loss of life. Coastal communities are particularly susceptible to the impacts of rising sea levels and intensified storm surges (EPA, 2023d).

Increasing carbon levels are making the oceans more acidic, posing challenges for corals and shellfish, hindering their ability to construct skeletons and shells, and potentially reshaping the oceanic ecosystems’ biodiversity and productivity (EPA, 2023h). However, the impacts of climate change on ocean ecosystems are most severe in tropical and polar regions. In the tropics, ocean warming is leading to widespread coral bleaching, outbreaks of coral diseases, and the destruction of coral reefs, which provide food and shelter for numerous marine organisms and support coastal communities (NOAA, 2023b). In the Arctic, sea ice is melting, reducing habitats for marine

mammals (EPA, 2023b). In Antarctica, warming has led to the collapse and shrinkage of ice shelves, changing patterns of wildlife behavior and threatening the ecosystem (EPA, 2023g). Melting ice and altered ocean currents raise sea levels, impact ocean circulation, and influence global weather patterns (EPA, 2023i).

Climate change has caused significant damage and progressively irreversible losses in terrestrial, freshwater, coastal, and marine ecosystems. The scope and intensity of these impacts surpass previous estimates. Climate change has deteriorated ecosystem structure and function, seasonal timing, resilience, and adaptive capacity. Globally, around half of assessed species have shifted toward the poles or higher elevations (Dawson, 2022). Local species losses have been driven by intensified heat, mass mortality on land and in oceans, and the disappearance of kelp forests (Rogers-Bennett & Catton, 2019). Although more gradual, processes like ocean acidification and rising sea levels are linked to climate change (EPA, 2023i). Some losses, like species extinctions, are irreversible. Other impacts, such as retreating glaciers and changes in mountain and Arctic ecosystems due to thaw, are nearing irreversibility (Intergovernmental Panel on Climate Change, 2019). The impact of climate change through time can be visualized using this [time machine](https://openstax.org/r/climate) (<https://openstax.org/r/climate>) developed by NASA.

HOW CLIMATE AFFECTS COMMUNITY HEALTH

[Access multimedia content](https://openstax.org/books/population-health/pages/14-4-climate-change-and-population-health) (<https://openstax.org/books/population-health/pages/14-4-climate-change-and-population-health>)

This video discusses some of the ways that climate and climate change impact the health of our communities and presents strategies for addressing these challenges.

Watch the video, and then respond to the following questions.

1. How do changing climate patterns impact vulnerable populations, and what specific health risks do these groups face in relation to extreme heat, storms and flooding, air quality, and pest-borne diseases?
2. In what ways can communities effectively prepare for the health risks associated with a changing climate?
3. The mental health toll of climate-related disasters often goes unnoticed. How can health care systems and communities address the psychological impact during and after extreme weather events?
4. How does the BRACE framework guide health departments in planning and executing coordinated responses to these challenges?

Extreme Weather

The impact of climate change is increasingly evident in the escalating intensity of tropical storms. The incidence of highly destructive U.S. hurricanes has tripled over the last century (Grinsted et al., 2019), with the prevalence of major hurricanes (Category 3 or above) in the Atlantic Ocean doubling since 1980 (Pfleiderer et al., 2022). The warming of ocean surfaces fuels hurricanes, intensifying evaporation and transferring heat from the oceans to the atmosphere. As a result, storms and hurricanes have stronger winds, heavier rainfall, and increased surges and flooding. Sea level rise amplifies this threat in coastal areas. Simultaneously, these hurricanes move more slowly, increasing the potential for damage. In 2018, Category 5 Hurricane Michael made landfall in Florida, causing catastrophic loss, with some communities completely destroyed (National Weather Service, 2019). Hurricane Maria, also Category 5, devastated the island of Puerto Rico in 2017 with widespread power outages, flooding, and landslides. The death toll was estimated at almost 3,000,000 (NOAA, 2017).

The frequency of heat waves has steadily risen, from an average of two per year in the 1960s to six per year in the 2020s, with the waves becoming more intense and lasting longer (EPA, 2023f). In July 2023, Phoenix, Arizona, endured a record of 31 days over 110 degrees (The Associated Press, 2023a). Extreme heat jeopardizes human health and labor efficiency in sectors with outdoor work such as agriculture and construction. Heat waves also impact environmental health, affecting animal and plant life and water availability and creating diminished capacity to support agricultural crops.

Extreme heat events are not limited to land. Marine heat waves (MHW), prolonged episodes of intense warming in seas and oceans, are becoming increasingly common and more severe. MHWs are closely monitored as they intensify extreme weather, expedite polar ice melting, and affect the health of marine life. As noted earlier, Earth's oceans play a pivotal role in storing excess heat, absorbing approximately 90 percent of the planet's retained heat from greenhouse gases emitted since 1970 (National Aeronautics and Space Administration, 2023). MHWs can have

significant consequences for marine ecosystems and fishing industries; higher temperatures stimulate the proliferation of harmful algal blooms, which are toxic to humans, birds, aquatic life, shellfish, and marine mammals and disrupt the migratory routes of marine life. In addition to MHWs, the surface of the ocean is warming; global surface temperatures reached and sustained record levels in July 2023, setting the record for the highest monthly increase above average in sea surface temperature (NOAA National Centers for Environmental Information, 2023c). On July 25, 2023, a heat record was likely broken when the water surface near Miami registered 38.4°C (101.1°Fahrenheit) (Kuta, 2023).

Prolonged elevated temperatures and drought are favorable conditions for the spread of wildfires, and the risks will likely amplify ([Figure 14.6](#)) (National Integrated Drought Information System, 2023). The summer of 2023 brought a record wildfire season to Canada; by August 22, even before the end of the season, over 37.8 million acres, more than double the previous record, had burned (Aljabs, 2023). Compare this to the one million acres that burned in the devastating 2018 California wildfires. As climate change progresses, wildfires are becoming more powerful, producing thick walls of smoke that are difficult to penetrate by tanker planes, with heat so intense that water drops can evaporate before reaching the ground. On August 8, 2023, a wildfire rapidly spread across Maui, Hawaii, destroying 2,170 acres including the historic town of Lahaina and thousands of residences and buildings (Hassan & Betts, 2023). The Lahaina fire killed 97 people, making it the fifth deadliest fire in U.S. history (Western Fire Chiefs Association, 2023).

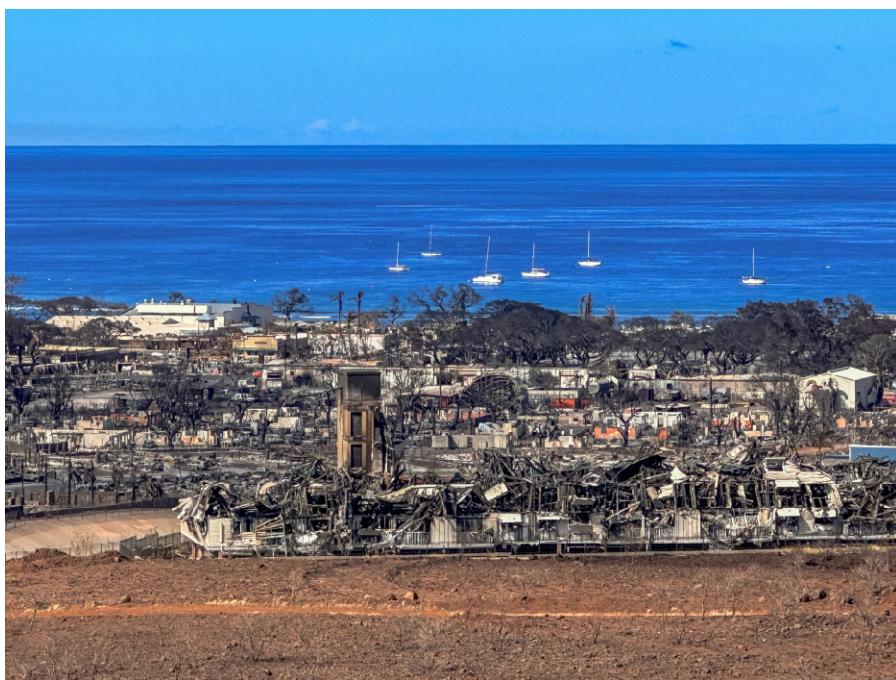

FIGURE 14.6 Wildfire devastated the community of Lahaina in Maui, Hawaii, during August 2023. (credit: “Maui community of Lahaina burned by wildfire” by State Farm/Flickr, CC BY 2.0)

Infectious Diseases

Alterations in the climate impact the prevalence, distribution, and transmission of diseases and the spread of infectious diseases. This relationship underscores the complex interaction between the environment, vectors, pathogens, and human health. Climate change can alter the distribution, seasonality, abundance, and life cycles of vectors that carry diseases such as Lyme, West Nile, Rocky Mountain spotted fever, malaria, plague, chikungunya, dengue, and Zika. Rising temperatures and heavier precipitation create favorable conditions for vectors, enabling them to spread and thrive in previously unaffected regions. Warmer temperatures expedite pathogen development within vectors, shortening their incubation periods and potentially escalating outbreaks. Higher water temperatures, shifting water salinity, and algal blooms cause waterborne diseases from *Vibrio* species such as cholera to become more prevalent. Modeling of *Vibrio* along with sea surface temperatures indicates a 51–108 percent increase in cholera cases in the United States by the year 2090 (relative to 1995) (Sheahan et al., 2022). The number of days conducive to *Vibrio* transmission has more than doubled from 53 to 107 (Aizenman, 2019).

Food System

Climate change threatens the production, quality, stability, supply chains, pricing, and distribution of food. Global agricultural productivity has slowed over the past 50 years due to climate change. Shifts in rainfall amounts, intensified weather events, and increased heat predictably drive down crop yields. For example, compared to 1981, the 2021 growing season for corn was shorter by an average of 9.3 days and for rice, 1.7 days (Romanello et al., 2022). As farmers struggle to adapt to changing conditions, they utilize more herbicides and pesticides, driving up the costs both of fertilizers and of the final food product. Furthermore, elevated atmospheric CO₂ levels reduce the concentration of nitrogen in plants, resulting in lower protein content in crops such as barley and soy. Ocean warming and acidification have adversely affected shellfish and fisheries in some regions, threatening the marine food supply. Rising sea levels and water intrusion increase soil salinity, damaging crops and increasing dietary salt. Extreme weather events such as droughts and heat waves have left millions vulnerable to food insecurity, especially in Africa and Asia, with an estimated 720 million to 811 million people suffering from hunger globally (Romanello et al., 2022). The supply of land and marine animals is also expected to continue declining, further reducing food output and escalating food prices. These factors tend to trigger food insecurity and steer consumers away from nutritious food to more calorically dense but nutrient-poor food, leading to outcomes ranging from nutrient deficiencies to obesity.

ONE EARTH—ENVIRONMENTAL SHORT FILM

[Access multimedia content \(<https://openstax.org/books/population-health/pages/14-4-climate-change-and-population-health>\)](https://openstax.org/books/population-health/pages/14-4-climate-change-and-population-health)

This video tells a story about the impact of profit-driven behavior and its impact on the environment.

Watch the video, and then respond to the following questions.

1. Why do you think the video doesn't have dialogue or narration? What message is it conveying?
2. In the face of these challenges, how can societies balance the economic needs of the present with the long-term well-being of the planet and its ecosystems?
3. What strategies can be implemented to encourage positive behavioral change and mitigate the adverse effects depicted in the film?

Impact on Physical Health

In 2021, the editors of more than 200 medical journals published a statement urging world leaders to rapidly reduce greenhouse gas emissions to avoid irreversible catastrophic harm, referring to climate change as the “greatest threat” to public health (Atwoli et al., 2021). The authors note that the evidence is unquestionable that continued increases in temperature may lead to unstoppable environmental change and global instability.

Climate change and related extreme events will significantly amplify health issues and premature deaths around the world. Increasingly frequent and intensifying extreme events will adversely impact population health by affecting air, water, and food availability, quality, and safety; exacerbating existing medical conditions; straining critical public health infrastructure and health care systems; and disrupting food chains and supply.

Health consequences include both the exacerbation of existing health issues such as respiratory and cardiovascular diseases and new challenges such as emerging zoonoses and water- and foodborne illnesses ([Figure 14.7](#)). Furthermore, the climate crisis may multiply threats, creating an acute situation for treatable conditions. For example, a power outage caused by an extreme weather event may lead a stable client with COPD to have an exacerbation.

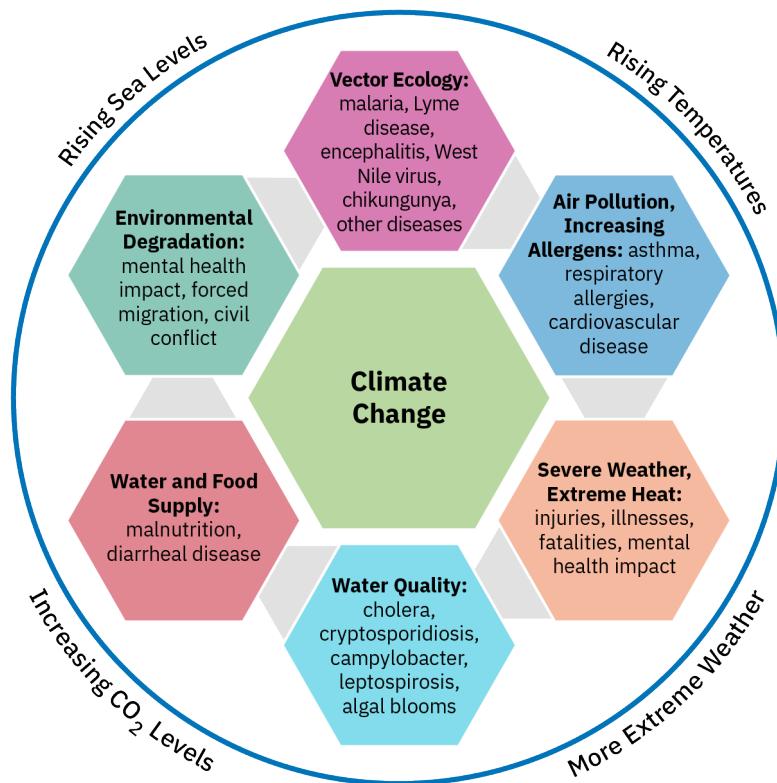

FIGURE 14.7 Climate change has a negative impact on health. (See CDC, 2022b; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Heat-related mortality among those over the age of 65 has increased by more than 50 percent over the last 20 years (Atwoli et al., 2021). Data reveals a clear connection between hot days and higher instances of heat-related illnesses like cardiovascular and respiratory issues (U.S. Global Change Research Program, 2018), renal failure, electrolyte imbalances, kidney problems, fetal health complications, and preterm births. In Phoenix, hospitalizations doubled for heat-related illnesses as well as injury, including burns sustained when falling onto pavement reaching a scorching 180 degrees.

Simultaneously, climate change worsens air pollution by elevating ground-level ozone and particulate matter, leading to worsened respiratory health, particularly for those with asthma and other respiratory diseases. Air quality is also impacted by wildfires; smoke is extremely hazardous to human health as it contains particulate matter, carbon monoxide, nitrogen oxides, and volatile organic compounds. Exposure to wildfire smoke leads to increased cases of respiratory and cardiovascular hospitalizations, emergency department visits, and chronic obstructive pulmonary disease. Communities thousands of miles from wildfires can experience unhealthy air quality from wildfire smoke, as notably occurred during the summer of 2023 when wildfire smoke from Canada spread deep into the United States, resulting in a 17 percent nationwide increase in visits to emergency rooms for asthma symptoms and a 46 percent increase in New York and New Jersey, jumping to 82 percent in New York State on the worst day of air quality, June 7 (The Associated Press, 2023b).

Diseases linked to food, water, animals, and insects, such as malaria, are projected to surge. Food supplies are shifting, with a decline in marine life and diminished agricultural output contributing to worldwide hunger. Even the food we eat is at risk for becoming less healthy, potentially leading to nutrient deficiencies.

Impact on Mental Health

Climate change has profound effects on mental health and psychological well-being. Temperature spikes, heat waves, and high humidity are linked to a decline in mental health outcomes and increased homicide and suicide rates (Romanello et al., 2022). Exposures to climate-related events can lead to a spectrum of mental health consequences, from minor stress to clinical disorders like anxiety, depression, post-traumatic stress, and even suicidal ideation. More indirectly, events like droughts disrupt agriculture, livelihoods, and resource availability.

Extreme weather events can lead to the loss of property, community, and life. Flooding or the threat of floods can trigger heightened levels of depression and anxiety, with these effects persisting for multiple years. Disasters disproportionately affect children, leading to mental health disorders due to forced displacement or the loss of family and community stability. After disasters and droughts, increased use of alcohol and tobacco becomes common. Climate change can intensify conflict and violence, further impacting mental health.

Individuals and communities may face multiple climate change effects. Exposure to multiple climate events can compound and accumulate over time, depleting both resilience and health (EPA, 2023k). Climate change amplifies existing health burdens; communities with degraded ecosystems and weak or outdated infrastructure face higher health risks. Vulnerable groups, including Indigenous communities, older adults, women, BIPOC populations, and individuals who identify as LGBTQIA+, disproportionately bear the consequences of climate change and are particularly susceptible to adverse mental health outcomes. Young people face heightened anxiety and depression and increased substance use. The impact of the climate crisis generated new concepts like **climate anxiety** (anxiety associated with climate change and its effects), **solastalgia** (nostalgia for ways of life lost due to climate change), **climate despair** (a sense of hopelessness and resignation regarding climate change), and **ecological grief** (an emotional response to the loss of parts of the ecosystem due to climate change) (Ostrander, 2022).

Impact on Vulnerable Populations

Globally, vulnerable populations bear a greater burden due to numerous potential factors such as insufficient community resources, suboptimal health care, and compromised infrastructure, including transportation, water, sanitation, and energy. Vulnerability to climate change depends on exposure to climate stressors, sensitivity to potential harm from the stressors, and adaptive capacity, or the ability to adjust, cope, and respond. Poverty heightens exposure and sensitivity, making those experiencing poverty more susceptible to harm while subsequently limiting adaptive capacity (U.S. Global Change Research Program, 2016).

Groups that experience more exposure to stressors may include those who are of lower socioeconomic status and unable to afford air conditioning or protective equipment such as masks, occupational groups such as outdoor workers who are exposed to extreme heat and insect-borne diseases, and those living in locations more prone to extreme climate change threats, such as droughts or hurricanes. Sensitivity is found among those who have preexisting health conditions such as asthma, pregnant people, and children, who are more sensitive to respiratory hazards. Adaptive ability may be limited in older adults, people with disabilities, and Indigenous peoples who rely on traditional ways for their lifestyles.

Strategies to Reduce Threats of Climate Change

Enormous investment is needed to reduce the threat and mitigate the impact of climate change (Atwoli et al., 2021). Since the environment and human health are inextricably linked, such investments will positively impact human health as well as planetary health. The CDC's agency-wide Climate and Health Task Force, established in 2021, aims to develop an integrative approach to climate and health in order to reduce the health impacts of climate change (CDC, 2022c). Health equity, environmental justice, and sustainability are central to the agency's mission and serve as a guiding strategy for addressing climate change. This section briefly describes strategies to reduce threats of climate change, including mitigation, adaptation, green infrastructure, and climate justice.

Mitigation and Adaptation

Efforts to address the impact of climate change can be divided into two categories: mitigation and adaptation.

Mitigation, or the reduction of greenhouse gas emissions and pollutants to slow the rate of change, aims to prevent the planet from warming beyond critical thresholds. Mitigation strategies include investing in renewable and clean energy sources, improving energy efficiency, protecting forests and wetlands, supporting sustainable agricultural practices, improving public transportation, and implementing policies to reduce emissions, such as the Paris Agreement, a global treaty adopted in 2015 to restrict the increase in global temperatures to less than 2°C above pre-industrial levels (United Nations, 2015), a target deemed essential to prevent the most serious consequences of climate change. [C-Roads \(<https://openstax.org/r/climateinteractive>\)](https://openstax.org/r/climateinteractive), an online virtual simulator, is a great tool to visualize the impact of potential climate change strategies such as the reduction of carbon emissions.

Adaptation, which refers to preparing for the projected impacts of climate change, focuses on minimizing the negative consequences of climate change while enhancing the ability of communities, populations, and systems to cope with its effects. Adaptation strategies include building more resilient infrastructure to withstand extreme

weather events, developing early warning systems for extreme events, implementing water management practices to address changing precipitation patterns, and creating plans for managing risks to public health. Adaptation focuses on minimizing negative consequences of climate change and enhancing the ability of communities, populations, and systems to cope with its effects. Both approaches are essential to address the multifaceted challenges of a changing climate and to ensure a sustainable future.

Green Infrastructure

Green infrastructure uses natural and seminatural elements to create sustainable spaces, especially in urban areas ([Figure 14.8](#)). Unlike traditional “gray” infrastructure of concrete and steel, green infrastructure utilizes nature, adding features like parks, community gardens, green roofs, rain gardens, permeable pavement, wetlands, and urban forests. There are several advantages to green infrastructure, including stormwater management, enhanced water and air quality, biodiversity preservation, temperature regulation, and the reduction of greenhouse gas emissions. Green spaces also counter the urban heat island effect, where cities become hotter due to human activity and surfaces absorbing heat. In addition to environmental benefits, green infrastructure boosts community health and cohesion, encouraging physical activity and social interaction. Mental health benefits include better sleep quality, increased social interaction, and exposure to nature.

FIGURE 14.8 Singapore's Supertrees mimic the function of natural trees, providing a vertical garden home, harnessing solar energy, and even collecting rainwater. (credit: “Supertrees” by Ray in Manila/Flickr, CC BY 2.0)

Climate Justice

Climate justice, an outgrowth of the environmental justice movement, focuses on addressing the unequal and disproportionate consequences arising from climate change. Vulnerable groups experience stark disparities on the impact of climate change, with older adults, children, economically disadvantaged communities, BIPOC individuals, and those with underlying health conditions carry a disproportionate burden. Living in communities that are more hazard prone, already polluted, or reliant on aging infrastructure increases the burden (Atwoli et al., 2021). For example, Indigenous populations in the United States face numerous health threats due to climate change. In Hawai'i and the Pacific Islands, saltwater contamination affects the water supply as sea levels rise. For those living in Alaska, thawing permafrost releases stored organic matter as well as hazardous agents once trapped in the frozen soil, destabilizing infrastructure and potentially contaminating water. Black, Hispanic, and Latino people comprise the majority of the outdoor workforce and are more likely to be impacted by air quality, extreme heat, and high humidity (EPA, 2021a). Older adults are a population of significant concern as their vulnerabilities are amplified by preexisting conditions, limited economic resources, and diminished social networks. The intersection of these multiple vulnerabilities further increases the susceptibility of older adults to climate-related impacts. The risk of injury and death during extreme weather events is pronounced among older adults as they may fear for their safety,

experience heat-related illnesses during power outages, experience disruptions to medical care, and have limited transportation options (EPA, 2022b).

Evaluating and addressing vulnerability must encompass an understanding of how these at-risk populations encounter disproportionate, multifaceted, and intricate health risks in response to the changing climate. Furthermore, all strategies, policies, and interventions to address climate change must put climate justice front and center to achieve environmental health equity.

COUNTDOWN ON HEALTH AND CLIMATE CHANGE

[Access multimedia content \(<https://openstax.org/books/population-health/pages/14-4-climate-change-and-population-health>\)](https://openstax.org/books/population-health/pages/14-4-climate-change-and-population-health)

The Lancet Countdown is considered one of the most comprehensive research studies on climate health. This video explains how the Lancet Countdown is tracking the health impacts of climate change.

Watch the video, and then respond to the following questions.

1. What specific health impacts does the Lancet Countdown report document?
2. What are the policy implications of the Lancet Countdown report? What actions can governments take to mitigate the health impacts of climate change?
3. What are the ethical implications of climate change? Do we have a moral obligation to protect future generations from the harms of climate change?

14.5 Nursing Practice and Responsibilities in Environmental Health

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 14.5.1 Describe strategies to integrate environmental health into nursing practice.
- 14.5.2 Identify strategies for nurses to address climate change.
- 14.5.3 Explain the role of the nurse as an advocate for environmental health and environmental justice.

Environmental health is an essential component of nursing practice as it has a significant impact on client and population health and outcomes. The integration of environmental health into nursing practice requires a series of strategic steps, including the use of a hierarchy of controls to prevent exposure to environmental contaminants. Let's look at the strategies for integrating environmental health into nursing practice, the importance of environmental justice, and the role of nurses as environmental advocates.

Nurses have a unique opportunity to be environmental advocates and leaders (Butterfield, 2021). Occupying an accepted role as educators and global citizens, nurses can leverage their public image and platform to promote environmental health through partnerships with colleagues in public health, medicine, behavioral health, schools, public offices, and the community (Butterfield, 2021).

Integrating Environmental Health into Nursing Practice

Nurses have a responsibility to address the impact of environmental burdens, discuss the effects of climate change, protect the rights of future generations, and advocate for vulnerable populations and communities (Lilienfeld et al., 2018). All nurses should strive to incorporate environmental science and translation into their research and practice (McCauley & Hayes, 2021). Nurses working with individuals should conduct environmental assessments along with collecting other client-specific information, considering the potential long-term impact of environmental exposures, including effects on physical health, mental health, and development.

Core Functions

Public health nurses perform the core functions of assessment, policy development, and assurance to serve as a framework for addressing environmental health issues and promoting healthier communities.

Assessment: Conduct comprehensive assessments to identify environmental health hazards and concerns in the community. Perform data collection and analysis to identify sources of pollution, assess exposure risks, and

evaluate the impact of the environment on health. Examples include performing environmental health assessments for individuals and communities.

Policy Development: Develop and advocate for policies and plans that promote a healthy environment. Collaborate with community partners and local governments to drive policies that positively impact the environment. Examples include advocating for clean water and policies that consider climate change.

Assurance: Monitor and evaluate the implementation and effectiveness of environmental policies and programs. Ensure action when hazards are identified or regulations violated. Examples include educating the community about contaminated water, ensuring that a safe alternative is provided, and advocating for infrastructure updates.

Prevention

Nurses have a pivotal role in safeguarding environmental health by implementing prevention interventions across the continuum of health care. It is critical to consider the upstream approach mentioned earlier in the chapter when developing interventions. For example, consider the community's potential hazards at each level of prevention. At the primary prevention level, nurses focus on promoting awareness, education, and advocacy to prevent environmental health risks before they occur. Secondary prevention encompasses early detection and intervention to mitigate risk and impact. Tertiary prevention focuses on minimizing the impact of already existing environmental health concerns by enhancing patient outcomes and facilitating recovery.

Primary Interventions:

- Provide education about the importance of environmental health and strategies for reducing risk and improving outcomes.
- Engage and empower communities to adopt healthy practices and policies that contribute to a cleaner environment, such as proper waste management and updating infrastructure.
- Advocate for policies to reduce air pollution and hazardous waste in the community.
- Advocate for policies to promote environmental protection, such as green building practices.

Secondary Interventions:

- Conduct regular environmental health assessments to identify individuals, groups, and communities at risk.
- Establish surveillance systems based on the community's potential hazards to monitor environmental health indicators, detect signs of issues, and intervene promptly.
- Screen for home hazards such as lead and mold.

Tertiary Interventions:

- Provide care and interventions to individuals affected by severe health consequences of environmental hazards.
- Develop emergency response plans specific to the community's hazards and needs to manage environmental disasters and extreme weather events.
- Engage in research to better understand the health impacts of various environmental hazards among clients.

Climate Change, Justice, and Advocacy

Nurses have distinctive strengths for addressing climate change. As the most trusted professionals in the United States, nurses are positioned to be powerful messengers for climate-related information. Nurses are trained communicators and often serve as the first point of contact for health and health care, providing an opportunity to incorporate environmental health assessments, climate change education, and interventions. Nurses working in the community are closely connected to vulnerable populations and can address issues of climate equity and justice ([Figure 14.9](#)) (Butterfield et al., 2021). Becoming involved in a professional nursing organization promoting climate justice provides nurses with resources and a platform from which to make transformative changes (Alliance of Nurses for Healthy Environments, 2023).

FIGURE 14.9 Young people mobilize for climate justice. (credit: “Kids Want Climate Justice, Minnesota March For Science, St Paul” by Lorie Shaull/Flickr, CC BY 2.0)

Primary Interventions:

- Educate the community about the health risks of climate change (Lokmic-Tomkins et al., 2023).
- Encourage community engagement with climate change mitigation efforts, such as community gardens, recycling programs, and energy-efficient practices (Salvador Costa et al., 2023).
- Provide information on adaptive behaviors to increase resilience, such as staying hydrated during heat waves.
- Collaborate with local authorities to advocate for climate-resilient infrastructure such as renewable energy initiatives and developing clean, efficient, and adequate public transportation (Salvador Costa et al., 2023).
- Ensure that communities are prepared for extreme weather events by promoting the development of cooling centers, evacuation routes, and emergency shelters.
- Facilitate connections between community members and community partners to increase social cohesion and resilience.
- Integrate climate-focused education and patient-centered conversations into nursing practice (Lokmic-Tomkins et al., 2023).

Secondary Interventions:

- Conduct screenings to identify vulnerable populations within the community and develop strategies to protect their health during climate-related events.
- Ensure that community members receive timely information and advice on staying safe, such as staying indoors during extreme heat or using masks during poor air quality periods.
- Establish or ensure surveillance systems to monitor health outcomes associated with climate change (Lokmic-Tomkins et al., 2023).

Tertiary Interventions:

- Establish plans for providing health care services in the aftermath of climate-related events.
- Ensure that health care facilities are equipped to manage crises triggered by extreme weather events and climate-related disasters (Salvador Costa et al., 2023).
- Train health care professionals to recognize and address health issues related to or exacerbated by climate change.
- Evaluate the effectiveness of interventions and policies aimed at mitigating and adapting to climate change health risks and recommend improvements based on findings.
- Work with communities to adapt to identified climate change risks and needs (Dion et al., 2022).

- Provide mental health support and referrals for those affected by the psychological stressors of climate-related events.

CASE REFLECTION

The Nurse's Role in Advocating for a Healthy Environment

Let's continue following Nurse Regis, who has been caring for Mr. Harper. Read the scenario, and then respond to the questions that follow.

Having established a link between Mr. Harper's deteriorating health and his environmental conditions, Nurse Regis decides to advocate for the wider community, arranging for the county to conduct a risk assessment, pollutant measurement, and environmental monitoring. Nurse Regis also initiates an educational intervention to inform community members about the potential health hazards in their environment and strategies to mitigate them. During the session, several neighbors express concern about the increasing amount of rain and runoff in the area, especially since the damp conditions have led to mold in several homes.

1. What is the nurse's role in advocating for a community facing environmental health issues? What specific steps and actions should be taken?
 2. How might the precautionary principle impact decisions for this community?
 3. What interprofessional collaborations can the nurse initiate to address the environmental health concerns in this community?
 4. How might climate change continue to impact the health of Mr. Harper and his neighbors? What actions might be taken to mitigate the risks they face due to climate change?
-

Chapter Summary

14.1 Understanding Environmental Health

Environmental health aims to prevent illness, death, and disability by reducing exposure to harmful environmental conditions and promoting behavior change. Environmental health addresses primary and secondary causes of illnesses and injuries, encompassing topics such as air quality, water quality, food safety, hazardous waste management, and occupational health. Hazardous waste is dangerous or potentially harmful to human health or the environment and originates from sources including industry, health care facilities, and households. Environmental health professionals monitor air quality and work to reduce pollutants to protect human health. Vulnerable populations, such as children, older adults, and low-income communities, are at higher risk from environmental burdens, and creating healthier environments can prevent a significant portion of the worldwide burden of disease.

14.2 Environmental Exposure and Health Outcomes

Environmental hazards and exposure are a growing concern, with factors like temperature and pollution impacting health in individuals and populations. Accurate information and risk management models are crucial for understanding and addressing environmental risks and empowering individuals and communities to take action. Environmental hazards originate from various sources, including industrial emissions and human activities, and can have adverse effects on human and animal health.

Key Terms

adaptation the process of adjusting or changing practices, infrastructure, and behaviors to minimize the negative effects of climate change by reducing vulnerabilities and enhancing resilience strategies to prepare for and cope with the projected impacts of climate change

Anthropocene current geological period representing the profound impact of human activities on Earth's ecosystems, driven by factors like industrialization, urbanization, deforestation, and fossil fuel consumption

bioaccumulation the gradual accumulation of contaminants, such as heavy metals like mercury and lead, within the tissues of living organisms.

biological agents significant environmental health

14.3 Environmental Health Assessment

The health of our environment is a crucial aspect of our overall well-being. With the increasing awareness of environmental pollution, it is essential to identify ways to measure pollutants in our environment.

14.4 Climate Change and Population Health

Green and sustainable development aims to balance environmental sustainability with social and economic growth, addressing climate change impacts on the environment and human health. Ecosystem management and restoration play a crucial role in reducing greenhouse gas emissions, mitigating deforestation, and decreasing carbon dioxide levels in the atmosphere. Implementing green infrastructure and investing in energy-efficient cooling infrastructure and green spaces can help cities adapt to climate change, mitigate heat effects, and promote climate change adaptation.

14.5 Nursing Practice and Responsibilities in Environmental Health

Nurses play a crucial role in promoting and protecting public health. They need knowledge of environmental health to recognize and manage environmental risks that could impact their clients. Environmental health impacts client outcomes and health care workers' well-being, and integration requires strategic steps and a hierarchy of controls to prevent exposure to contaminants. Nurses promote environmental justice as advocates, leveraging their platform to address climate change's effects on public health and discussing the rights of future generations and vulnerable groups.

hazards that include molds, dust mites, cockroaches, pollen, bacteria, viruses, protozoa, parasitic worms, and pet dander, saliva, and waste

biomonitoring process of measuring and assessing the concentration of specific biological markers, such as chemicals, toxins, or pollutants, in biological samples like blood, urine, or tissue to evaluate the extent of exposure to these substances

built environment the human-made surroundings where people live, work, and engage in recreation, including buildings, infrastructure, transportation systems, parks, and all other physical elements created by human design and construction

carcinogens cancer-causing agents

chemical agents chemicals like heavy metals,

pesticides, polychlorinated biphenyls (PCBs), chlorofluorocarbons (CFCs), endocrine-disrupting chemicals (EDCs), and sulfur dioxide (SO_2) used in agriculture, industry, and the burning of fossil fuels for transportation and electricity	environmental health hazards conditions or factors in the environment that pose a risk to human health; can be categorized into biological, chemical, and physical agents
climate anxiety anxiety associated with climate change and its effects on the planet's health, the ecosystem, and human life	environmental justice the fair and equitable treatment and meaningful engagement of every individual, irrespective of race, color, national origin, or socioeconomic status, in the development, execution, and enforcement of environmental laws and policies
climate change profound and lasting shifts in Earth's climate patterns and conditions; while natural processes have historically shaped the planet's climate, the term climate change refers to the significant and rapid alterations occurring since the mid-20th century and largely attributed to human activities	Environmental Theory a theory developed by Florence Nightingale that focuses on the impact of the environment on nursing care; involves utilizing the client's environment to facilitate their recovery and recognizing the influence of external factors on health and well-being
climate despair a response to the overwhelming and seemingly insurmountable challenges posed by climate change manifested by a deep sense of hopelessness and resignation	exposure assessment the process of estimating, measuring, characterizing, and modeling the frequency, magnitude, and duration of contact between individuals or populations and potentially harmful agents or substances in the environment
climate justice the fair and equitable treatment of all individuals and communities, particularly those disproportionately affected by the consequences of climate change and environmental degradation; involves addressing climate-related issues with a focus on ensuring that the burdens and benefits of climate action are distributed equitably	mitigation strategies to reduce greenhouse gas emissions and pollutants to slow the rate of change; aims to prevent the planet from warming beyond critical thresholds
cumulative impacts the total harm to humans resulting from the combination and interaction of multiple factors such as pollution, socioeconomics, and preexisting conditions	mutagens radioactive substances found in nuclear waste and radon that alter a person's DNA
ecological grief the emotions of loss experienced by individuals or communities due to profound changes in the ecosystem caused by climate change	neurotoxins substances that can lead to adverse effects on the nervous system
environmental agents substances or elements present in the environment that can impact human health; can include infectious organisms, chemicals, radiation, noise, and diet	particulate matter a mixture of solid particles and liquid droplets; can penetrate the respiratory system, irritating the lungs and exacerbating health conditions such as asthma and bronchitis; long-term exposure to particulate matter has been associated with an increased risk of cardiovascular diseases, respiratory illnesses, and even premature death
environmental burden the harm caused by environmental factors on human health and well-being, which includes damage, destruction, or impairment of natural resources	physical agents environmental conditions such as noise, temperature, vibrations, and lighting that can have an adverse impact on the quality of the environment and affect work performance
environmental epidemiology focuses on the links between environmental exposures and human health outcomes; environmental epidemiologists identify potential environmental health hazards, quantify risk, and explore how different environmental factors, such as air and water pollution, chemicals, radiation, and climate change, impact health	precautionary principle directs decision makers to be proactive in safeguarding the environment and public health rather than waiting for conclusive evidence of harm; shifts the burden of proof, or responsibility, to those advocating for a particular action, such as building a new power plant, to demonstrate that it will not cause harm to the environment or community
environmental health the branch of public health that aims to prevent illness, death, and disability by reducing exposure to harmful environmental conditions and promoting behavior change	solastalgia psychological distress and sadness experienced by individuals when they witness the negative transformation of their home environment due to environmental changes such as climate

change, deforestation, or industrial development; a nostalgia for the loss of traditional lifeways or those of one's childhood

teratogens substances that can cause defects in a developing embryo

toxicodynamics examines the impact of chemicals

on the body and health

toxicokinetics the study of how chemicals are absorbed, metabolized, and eliminated

toxicology a scientific discipline that examines how artificial or natural hazards can cause undesirable effects in living organisms

Review Questions

1. What is the primary goal of integrating environmental health into nursing practice?
 - a. Improving health care infrastructure
 - b. Enhancing patient satisfaction
 - c. Promoting environmental justice
 - d. Reducing health care costs

2. Which action will the public health team take during the Exposure Assessment stage of the EPA's four-step risk assessment following a train derailment resulting in a toxic chemical spill?
 - a. Identifying potential negative outcomes due to exposure to the toxic chemicals
 - b. Identifying how the amount of exposure relates to the severity of negative health outcomes
 - c. Quantifying the extent, frequency, and length of contact of the community with the toxic chemicals
 - d. Determining how the toxic chemicals are absorbed, metabolized, and eliminated from the body

3. Which statement describes the actions of a nurse who follows Nightingale's Environmental Theory?
 - a. Identifying strategies to reduce climate change
 - b. Encouraging the use of public transportation
 - c. Promoting environmental justice for all people
 - d. Using the client's environment to assist in recovery

4. Which action by the nurse is an example of engaging in environmental justice?
 - a. Using the environment to assist in client recovery
 - b. Encouraging communities to engage in composting
 - c. Eliminating lead-based paint in public housing
 - d. Educating the community on proper disposal of hazardous materials

5. Which data is the nurse examining when assessing the presence of certain chemicals in the blood and urine samples from a community?
 - a. Toxicology data
 - b. Biomonitoring data
 - c. Exposure assessments
 - d. Environmental burden

6. The nurse is performing an environmental assessment in an apartment building where many people have reported burning eyes, skin rash, stuffy nose, and sore throat. Which type of hazard does the nurse anticipate is present in the apartment building?
 - a. Radon
 - b. Mice
 - c. Mold
 - d. Lead

7. Which strategy should the nurse include in a community education program about improving environmental health?
 - a. Composting organic matter
 - b. Disposing of electronics with household trash
 - c. Using rainwater harvesting for drinking water

- d. Keeping windows tightly shut
- 8.** A community nurse is educating the community about mitigation strategies to address climate change. Which strategy would the nurse teach to the community?
- a. Implementing early warning systems for extreme temperatures
 - b. Improving public transportation
 - c. Changing building codes to withstand hurricanes
 - d. Distributing masks for high-pollution days
- 9.** Which environmental health activity would the nurse perform while engaged in the core public health function of assurance?
- a. Educating the community about the need to boil contaminated drinking water
 - b. Collecting data about health issues related to contaminated drinking water
 - c. Developing policies to regulate the discharge of pollutants into the waterways
 - d. Assessing measures to reduce exposure to contaminated water
- 10.** Which intervention by the nurse is an example of a tertiary prevention strategy to improve environmental health?
- a. Conducting risk assessments for environmental contaminants
 - b. Developing emergency response plans for environmental hazards
 - c. Performing regular community environmental health assessments
 - d. Implementing pollution prevention strategies

CHAPTER 15

Health Promotion and Disease Prevention Strategies

FIGURE 15.1 Immunizations, such as the influenza vaccine, seen here, are one way public health nurses contribute to health promotion and disease prevention. (credit: modification of work by Brandon Clifton/CDC, Public Domain)

CHAPTER OUTLINE

- 15.1 Defining Health Promotion and Disease Prevention
- 15.2 Health Promotion and Disease Prevention Interventions
- 15.3 Theories and Models
- 15.4 Barriers and Opportunities for Health Promotion and Disease Prevention

INTRODUCTION A county health department provides community health screenings in a pharmacy parking lot. A nurse asks 25-year-old Deanna if her 148/88 mm Hg blood pressure reading is usual for her. Deanna doesn't know, but she says that her grandparents and parents all have high blood pressure. The nurse questions Deanna about any recent headaches, weight gain, swelling in her hands or feet, or visual changes. Deanna denies experiencing any of these. The nurse describes the genetic and behavioral risk factors for high blood pressure as well as potential complications with high blood pressure, such as strokes. The nurse also explains to Deanna that high blood pressure can be reduced with certain healthy behaviors, such as limiting sodium intake and engaging in regular physical activity, and the two discuss an infographic illustrating these and other healthy behaviors. The nurse also provides Deanna with a dated card that indicates Deanna's blood pressure measurement and encourages Deanna to make an appointment with her primary health care provider. Deanna says she'll do so, as she doesn't want to have a chronic illness at such a young age.

If not for the community health screening, Deanna may not have discovered that she has a health problem that she needs to address. Unidentified, and therefore untreated, health conditions can lead to bigger issues. According to

the U.S. Department of Health and Human Services (USDHHS) (2022), about 11 million Americans do not know their blood pressure is elevated and, therefore, are not receiving any treatment to control it. This chapter will discuss ways that health promotion and disease prevention can positively impact individual and population health outcomes. It will describe the role of the nurse in performing health promotion and disease prevention.

15.1 Defining Health Promotion and Disease Prevention

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 15.1.1 Define health promotion.
- 15.1.2 Define disease prevention.
- 15.1.3 Differentiate between health promotion and disease prevention.

The terms *health promotion* and *disease prevention* are often used together to describe a mechanism for improving health outcomes. Although the U.S. Department of Health and Human Services (n.d.-a) Healthy People 2030 initiative states that “promoting health and well-being and preventing disease are linked efforts that encompass physical, mental, and social health dimensions” (para. 6), health promotion and disease prevention are two individual processes. Though their functions overlap, they are separate and distinct entities.

A Closer Look at Health Promotion

Organizations define health promotion in different ways. The Ottawa Charter for Health Promotion, described in detail later in this chapter, offers the most widely accepted description of health promotion:

Health promotion is the process of empowering people to increase control over, and to improve, their health (World Health Organization [WHO], 1986). This must involve addressing physical, mental, and social well-being. In order to accomplish health promotion, an individual or group must be able to identify and realize goals related to health, satisfy needs, and change or cope with the environment. Health, according to the WHO (1986), should be seen not as the objective of living but instead as a resource for everyday life. Clearly, health promotion is a responsibility of the health sector. Sectors are critical, distinct parts of society. We must view health promotion as not just the responsibility of the health sector but as an obligation of multiple sectors, such as the environmental, educational, and technological sectors as well as others (WHO, 1986, para. 1).

The process of health promotion includes activities for individuals, the community at large, and populations at increased risk of negative health outcomes. Health promotion is empowering for individuals and communities, and it can be used in both active and passive ways. For instance, adding fluoride to public drinking water is a passive form of health promotion at the community level. Brushing teeth and getting regular dental assessments are active forms of health promotion at the individual level.

Health Promotion Behaviors

Health promotion behaviors aim to improve the well-being, mental health, and quality of life of individuals and communities (Walker et al., 1995; see [Table 15.1](#)). There are six dimensions of health promotion behaviors that describe certain behaviors by which a person engages with their health. These dimensions empower (or not) a person’s control over and improvement of their health.

Dimensions	Definition	Individual-Level Example	Community-Level Example
Responsibility	An active sense of accountability for one's well-being; incorporates attention to one's health, educating oneself about health, and using informed consumerism when seeking professional assistance	A client asks their provider for information about a prescribed medication, including side effects and interactions	North Carolina's Community Health Coalition (2023) connects leaders and practitioners in medicine, education, mental health, faith organizations, law, finance, the military, and social advocacy to achieve the goal of health equity for all.
Physical Activity	Regular participation in light, moderate, and/or vigorous activity, either specifically for the purpose of fitness and health or incidentally as part of daily life	A person chooses to take the stairs rather than the elevator	LIFE: Living well through Intergenerational Fitness and Exercise (Rural Health Information Hub, 2022) combines exercise and video games to encourage fun and safe physical fitness among older adults in rural areas.
Nutrition	The informed selection and consumption of foods essential for sustenance, health, and well-being, including a healthy diet as recommended by the U.S. Department of Agriculture (USDA)	A shopper examines a nutrition label on a pre-packaged meal prior to making a purchase	Meals on Wheels America (2021) visits seniors to deliver nutritious meals and perform safety checks, supporting seniors' independence and dignity.
Interpersonal Relations	Communicating to achieve a sense of intimacy and closeness within meaningful relationships with others; includes the sharing of thoughts and feelings via verbal and nonverbal messages	Two friends meet to share experiences they had throughout the previous week, including the highs and lows of everyday life	The National Health Education Standards in the United States specifically include interpersonal communication as an essential element of effective health education in grades K-12 (Centers for Disease Control and Prevention [CDC], 2019b).

TABLE 15.1 Six Dimensions of Health Promotion Behaviors (See Walker et al., 1995.)

Dimensions	Definition	Individual-Level Example	Community-Level Example
Spiritual Growth	Creating inner resources through the following: <i>Transcending</i> : Opens one to the possibility of creation and change, connecting with their most balanced self and feeling inner peace <i>Connecting</i> : A feeling of harmony and wholeness within the universe <i>Developing</i> : One maximizes their potential for wellness; can occur through searches for meaning, finding a sense of purpose, or working toward life goals	A college student practices daily meditation	Austin Public Health (2023) offers Walking with Faith, in which members of all ages increase their physical activity, spiritual growth, and cultural awareness as they take virtual tours through various countries.
Stress Management	Identification and mobilization of both psychological and physiological resources to control or reduce tension	The CEO of a large company takes 15 minutes each morning to practice mindfulness meditation	Thrive! is a comprehensive University of Michigan (2023) stress management and prevention program that aims to foster employees' psychological well-being by energizing the work climate, enhancing relationships, and maximizing personal strengths.

TABLE 15.1 Six Dimensions of Health Promotion Behaviors (See Walker et al., 1995.)

Nurses' Role in Health Promotion

As mentioned earlier, health promotion is often an **intersectoral** endeavor (WHO, 2023a)—that is, one that involves several sectors of society and that can occur within or outside the health care sector. Actions taken by health, education, housing, and local government sectors collaborating to enhance population health use an intersectoral approach (Oxford Reference, 2023). Because nurses can serve in a variety of roles in interprofessional practice, including care provider, educator, consultant, and advocate, they are in a unique position to contribute to intersectoral collaboration. Health promotion can involve the following:

- Assisting a client in developing personal health promotion behavior skills (individual)
- Assisting the community in strengthening actions to achieve better health (community)
- Creating supportive environments within society (population or public as a whole)
- Advocating for the adoption of public health policies (population or public as a whole)

Throughout the health promotion process, as nurses assist clients in developing personal health promotion behavior skills, they serve as care providers and educators. Assessment data may indicate the need to develop a client's personal health promotion behaviors. The nurse assumes the role of educator during the implementation stage. Effective education for change requires the nurse to have a good grasp of evidence-based practice and other scientific knowledge as well as educational theory, the teaching-learning process, and models specifically related to health behavior change (see [Theories and Models](#)). The nurse must support individual, and therefore social,

development by educating, informing, and improving clients' life skills (WHO, 2023a). When a client is informed and knowledgeable, they have the ability to make choices that can positively influence their health and their environment (WHO, 2023a). The nurse educates the client about their current situation and provides anticipatory guidance to help them meet and cope with health challenges as they move through the stages of the lifespan (WHO, 2023a). The role of the nurse as an educator is one of the most critical roles in health promotion. The nurse may also need to serve as educator in order to create supportive environments for health.

The nurse serves as consultant and advocate by performing community health promotion activities. Such activities strengthen clients' actions to achieve better health, resulting in environments that support better health (Iriarte-Roteta et al., 2020). A community is complex, frequently changing, and made up of interconnecting parts from which health cannot be separated. Planners can seek input from a public health nurse to understand the health and illness experiences of the community and implement beneficial changes for community health (American Public Health Association [APHA], 2022). For instance, a city council may request input from a public health nurse prior to installing a new splash park for children.

Nurses have a responsibility to advocate for access to health care, health promotion, disease prevention, and any other health-related issues. A variety of professional groups, including the American Nurses Association (ANA, 2015), the American Association of Colleges of Nursing (2021), and the International Council of Nurses (2021), support the nurse's role as policy advocate. According to the ANA (n.d.), "Advocacy is a pillar of nursing."

A Closer Look at Disease Prevention

Disease prevention involves undertaking specific population- and individual-based interventions geared toward decreasing the burden of both communicable and noncommunicable diseases and their associated risk factors (WHO Regional Office for the Eastern Mediterranean, 2023). The hallmark of communicable diseases is that they spread from one person to another, from an animal to a person, or from a surface or a food to a person (CDC, 2022). They may include pandemics and infectious disease outbreaks, vaccine-preventable diseases, human immunodeficiency virus (HIV), viral hepatitis, sexually transmitted infections (STIs), tuberculosis (TB), and others (see [Pandemics and Infectious Disease Outbreaks](#)). The CDC (2022) broadly defines noncommunicable diseases as chronic conditions that do not result from an acute or infectious process. Chronic diseases meet one or both of the following criteria: a disease that lasts 1 year or longer and requires ongoing medical attention or a disease that limits the activities of daily living. Noncommunicable diseases include chronic diseases such as heart disease, cancer, diabetes, and others, as discussed in [The Health of the Population](#).

Preventive Care

Another term for disease prevention is *preventive care*. According to the U.S. Centers for Medicare and Medicaid Services (CMS, n.d.), **preventive care** involves routine health care screenings, check-ups, immunizations, and counseling to prevent illness, disease, or health-related problems. Healthy People 2030: Preventive Care gives examples and connects preventive care to the Healthy People 2030 Objectives, as described in detail in [Planning Health Promotion and Disease Prevention Interventions](#).

HEALTHY PEOPLE 2030

Preventive Care

Healthy People 2030 Preventive Care Objectives focus on a broad range of goals, such as increasing the number of community health organizations that offer [prevention services](https://openstax.org/r/healthypeople) (<https://openstax.org/r/healthypeople>); increasing screening for various forms of cancer, depression, newborn hearing, and osteoporosis; promoting vaccinations; and increasing health care access and quality. Other topics include heart disease and stroke, oral health, pregnancy and childbirth, sensory or communication disorders, and sexually transmitted infections.

Nurses' Role in Disease Prevention

Nurses play an enormous role in disease prevention. The nurse's role as educator is especially important to prevention, as nurses are qualified to provide information, training, and education about a range of health-related, preventive topics. When people are educated about health behaviors, they experience better health outcomes (Zajacova & Lawrence, 2018).

The National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP, 2023), a branch of the CDC, indicates that 6 in 10 Americans live with at least one chronic disease. These largely preventable diseases are the leading causes of death and disability in the United States. For instance, tobacco use can lead to several forms of cancer. Diets high in sodium can lead to hypertension. Preventive care such as smoking cessation and dietary education can help prevent these chronic diseases from occurring. Nurses can educate their clients about these and other disease-preventing behavior changes. Recall Deanna from the case scenario. The nurse at the community health screening helped to identify a potential chronic health problem for Deanna and then provided Deanna with information she could use to help prevent the development or progression of hypertension.

Nurses apply evidence-based practice to prevent disease (see [Evidence-Based Decision-Making](#)). Using evidence from correlational or causal studies to examine the relationships between diseases and behaviors or risks for these diseases, the [U.S. Preventive Services Task Force \(<https://openstax.org/r/uspreventiv>\)](#) (USPSTF, 2021) makes recommendations about the effectiveness of clinical primary and secondary preventive services based on available evidence. These recommendations inform effective nursing practice. For example, nurses may inform clients of USPSTF recommendations for colorectal cancer screenings in adults and older adults, tobacco smoking cessation in adults, and folic acid intake by pregnant persons to prevent neural tube defects.

The Distinction Between Health Promotion and Disease Prevention

While the functions of health promotion and disease prevention overlap and they share many goals, they have differences. Disease prevention focuses on specific efforts at reducing the development and severity of chronic diseases and other morbidities. While health promotion efforts can lead to such a reduction, health promotion can also occur unlinked to disease and simply be used to promote overall well-being. Some examples of health promotion that is unlinked to prevention of a specific disease may include the following:

- Physical activity campaigns to encourage regular exercise
- Nutrition education regarding balanced diets and portion control
- Stress management workshops to enhance mental well-being
- Workplace wellness programs to support employees' physical and mental health
- Smoking cessation programs to promote a smoke-free environment
- Mental health awareness campaigns to reduce stigma
- Environmental health initiatives to promote clean air, clean water, and safe living

Another distinction between health promotion and disease prevention relates to the strategies used for each. Health promotion interventions often involve education, awareness campaigns, behavior change programs, and community engagement to encourage healthy behaviors and create supportive environments for health. Disease prevention strategies more specifically target known risk factors or disease processes.

Another distinction often occurs at the conceptual level. In this case, health promotion is primarily concerned with the social determinants of health (SDOH) (WHO, 2023a). SDOH, as described in [Social Determinants Affecting Health Outcomes](#), are “the conditions in the environments where people are born, live, learn, work, play, worship and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks” (USDHHS, n.d.-b). Therefore, various sectors typically collaborate with the health care sector to contribute to addressing SDOH. For example, the WHO Regional Office for the Eastern Mediterranean (2023) describes the collaboration of the governmental sector (policy development), the tobacco manufacturing sector, the education sector, and the health care sector in combating tobacco use. Disease prevention, in contrast, has primarily been concentrated within the health care sector (WHO Regional Office for the Eastern Mediterranean, 2023).

15.2 Health Promotion and Disease Prevention Interventions

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 15.2.1 Describe the five key action areas of health promotion as defined in the Ottawa Charter.
- 15.2.2 Describe the natural history of a disease to identify opportunities for prevention and control.
- 15.2.3 Apply the four levels of prevention (primordial, primary, secondary, and tertiary) to plan health promotion and disease prevention interventions.

Health promotion and disease prevention interventions can improve health throughout the lifespan. A nurse in most

care environments can perform health promotion and disease prevention interventions at the individual, community, and population levels.

Ottawa Charter for Health Promotion, 1986

The first International Conference on Health Promotion in Ottawa, Canada, in 1986 produced the **Ottawa Charter for Health Promotion** with the aim of achieving (or establishing) more effective health education strategies (WHO, 2023a). The Charter provided a common definition of health promotion, three core values, a framework of three strategies, and five areas of action. The nurse plays an important role in each.

HEALTH PROMOTION AND THE OTTAWA CHARTER

[Access multimedia content \(<https://openstax.org/books/population-health/pages/15-2-health-promotion-and-disease-prevention-interventions>\)](https://openstax.org/books/population-health/pages/15-2-health-promotion-and-disease-prevention-interventions)

This video describes the Ottawa Charter, a landmark document that was influential in providing guidance to the goals and concepts of health promotion for public and population health programs worldwide.

Watch the video, and then respond to the following questions:

1. Which action area in the Ottawa Charter links most closely to the SDOH we address today?
2. How can the nurse participate in each of the three strategies for health promotion identified by the Ottawa Charter?

The Natural History of Disease

To identify opportunities for prevention and control, it is first necessary to recognize the **natural history of disease**—that is, the progression of a disease process in an individual over time in the absence of treatment (Kisling et al., 2023). The five stages in the natural history of disease are underlying, susceptible, subclinical, clinical, and recovery/disability/death (see [Table 15.2](#)).

Stage	Definition	Example
Underlying	Risk factors may lead to the development of a disease. These can include social and environmental factors.	A client who is sedentary for over 8 hours daily is at risk for developing obesity. Therefore, the client is in the underlying stage of disease.
Susceptible	The state of being predisposed to, or sensitive to, developing a certain disease. Genetic, environmental, or a combination of both factors may contribute to this.	A client who lives in a region with very poor air quality is more susceptible to developing lung disease due to their environment.
Subclinical	An illness that stays below the surface of clinical detection and has no recognizable clinical findings. In infectious diseases, this is the incubation period, or the time from exposure to onset of disease symptoms. The clinical latency period is the period for which an infection is subclinical.	The results of routine bloodwork indicate a client has hypothyroidism. They have difficulty believing they have a thyroid problem because a relative with hypothyroidism gained weight, lost their hair, and experienced constipation. The client has none of these symptoms because they are in the subclinical stage of disease.
Clinical	A disease with recognizable clinical signs and symptoms.	The client's relative in the above (subclinical) example is in the clinical stage of hypothyroidism.
Recovery/ Disability/ Death	Ultimately, a disease process ends in either recovery, disability, or death.	A client has an untreated HIV infection. This terminates with AIDS and death over a 10-year period.

TABLE 15.2 Five Stages in the Natural History of Disease (See Kisling et al., 2023.)

Recognition of each disease stage allows the nurse to identify the corresponding levels of prevention, which can then be applied to plan health promotion and disease prevention interventions.

Levels of Prevention

The five levels of prevention—primordial, primary, secondary, **tertiary**, and quaternary—described in [Foundations of Public/Community Health](#) correspond to the five stages of disease described in [Table 15.2](#). Combined use of prevention strategies in a community at the macro-level (or upstream) can lead to the prevention of individual (micro-level, or downstream) complications of an exhibited disease (Kisling & Das, 2022). [Table 15.3](#) identifies the levels of prevention as they correspond to the disease stages.

Levels of Prevention	Targeted Stage of Disease	Characteristics of Level of Prevention	Example of Level of Prevention
Primordial Prevention	Underlying	<ul style="list-style-type: none"> • Risk-factor reduction targeted to an entire population through focus on social and environmental conditions • Prevention of the development of risk factors for disease • Typically promoted through laws and policy (multi-sectoral) • Often aimed at children to decrease as much risk exposure as possible • Targets the underlying social conditions that promote disease onset 	Improving an urban neighborhood's access to safe sidewalks to promote physical activity, which in turn will decrease risk factors for obesity, cardiovascular disease, and diabetes
Primary Prevention	Susceptible	<ul style="list-style-type: none"> • To prevent a disease from occurring • Target population is healthy individuals • Modifies existing risk factors to prevent the development of disease • Commonly involves activities to limit risk exposure or increase immunity of those at risk to prevent a disease from progressing in a susceptible individual to subclinical disease 	Conducting an immunization campaign targeting school-aged children, with the goal of preventing the occurrence of vaccine-preventable diseases and promoting overall community health

TABLE 15.3 Five Levels of Prevention

Levels of Prevention	Targeted Stage of Disease	Characteristics of Level of Prevention	Example of Level of Prevention
Secondary Prevention	Subclinical	<ul style="list-style-type: none"> Emphasizes early disease detection Targets healthy-appearing individuals with subclinical forms of disease 	Organizing a breast cancer screening program in collaboration with local community organizations, such as women's groups and senior centers, to raise awareness about the importance of screenings and encourage women to participate
Tertiary Prevention	<ul style="list-style-type: none"> Clinical Recovery, Disability, Death 	<ul style="list-style-type: none"> Targets both the clinical and outcomes stages of disease Implemented in symptomatic individuals Aims to reduce the severity of disease and any associated sequelae 	Referring community members who live with chronic joint pain and limited mobility to a local rehabilitation center, which serves as a community hub for rehabilitation service activities that encourage community members to engage with one another, share experiences, and provide mutual support throughout their rehabilitation journey
Quaternary Prevention	N/A	<ul style="list-style-type: none"> Targets clients with illness but without disease Action taken to protect persons from medical interventions that are likely to cause more harm than good 	Cautioning a population of clients who are complete post-hysterectomy against the continuing need for Pap smears

TABLE 15.3 Five Levels of Prevention

HEALTHY PEOPLE 2030

Vaccination

Healthy People 2030 vaccination objectives focus on increasing the proportion of children and adults who [receive recommended vaccinations](https://openstax.org/r/healthypeoplevaccina) (<https://openstax.org/r/healthypeoplevaccina>) and maintain vaccination coverage. This objective category includes recommendations for reducing the number of children who do not get recommended vaccines by age 2 in order to reduce outbreaks of vaccine-preventable diseases like measles, pertussis, and mumps.

While primordial and primary prevention appear similar, the actual existence of risk factors is key to differentiating them. **Primordial prevention** prevents the development of risk factors for disease. **Primary prevention** modifies existing risk factors to prevent the development of disease (Weintraub et al., 2011). In addition, primordial prevention generally is intersectoral rather than limited to those within the health sector. The other levels of prevention, as noted previously, are mainly limited to the health sector. This information can be useful to the nurse in planning health promotion and disease prevention interventions.

Another important factor the nurse should consider when planning involves the approach to prevention. The **high-risk approach** targets prevention only to those who are identified to be at high risk for disease. This could be an

individual or a group who is likely to have an increased incidence of a disease based on the presence of known risk factors for the disease or characteristics that are associated with a higher incidence of disease. Even when a group is involved, the high-risk approach focuses on the individual and their risk behaviors (Wilson et al., 2017). An example of this approach would be a smoking cessation intervention for a client.

In contrast, a **population approach** implements prevention strategies across an entire population, many of whom are not necessarily at high risk (Rose, 1992). An example of a population approach to prevention would be a citywide anti-smoking law inside public buildings. In most cases, a population approach requires intersectoral involvement, while the high-risk approach is usually limited to the health sector. Both approaches can be used at the primary and **secondary prevention** levels (Platt et al., 2017). Sometimes a combination of both approaches is used to prevent disease.

AN OVERVIEW OF THE LEVELS OF DISEASE PREVENTION

[Access multimedia content \(<https://openstax.org/books/population-health/pages/15-2-health-promotion-and-disease-prevention-interventions>\)](https://openstax.org/books/population-health/pages/15-2-health-promotion-and-disease-prevention-interventions)

To address disease prevention as a whole, it is necessary to look at different levels of prevention as they apply to population health. The video “Levels of Disease Prevention and Approaches” reviews the definition of prevention, the process of prevention, the four levels of prevention, and two approaches to prevention.

Watch the video, and then respond to the following questions.

1. A client at risk for diabetes has their blood glucose and HgA1C levels tested periodically. Which level of prevention does this describe?
2. A public health nurse provides a presentation on healthy eating habits to first-grade children. Which level of prevention does this describe?

UNFOLDING CASE STUDY

Part A: Health Screening Follow-Up

Read the scenario, and then answer the questions that follow.

After receiving education from the nurse at the community health screening, Deanna decides to call and make an appointment with her primary provider to follow up on the high blood pressure reading. The receptionist at the provider’s office provides Deanna with an appointment in a week, noting Deanna’s reason for the visit is “BP 148/88 at community screening, denies other symptoms.” The nurse in the provider’s office reviews Deanna’s file in preparation for the office visit. The nurse notes that Deanna has not seen the provider for a few years, has no high blood pressure readings documented in the past, and has a family history of hypertension.

1. Which stage of the natural history of disease should the nurse most likely suspect for Deanna?
 - a. Susceptible
 - b. Clinical
 - c. Recovery
 - d. Subclinical
2. If the provider diagnoses Deanna with hypertension and prescribes medication to treat the disease, which form of prevention will Deanna receive?
 - a. Primary prevention
 - b. Secondary prevention
 - c. Tertiary prevention
 - d. Primordial prevention

15.3 Theories and Models

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 15.3.1 Describe health promotion models at the systems level that can guide the identification, development, and implementation of interventions.
- 15.3.2 Describe health promotion models and theories at the intrapersonal level that can guide the identification, development, and implementation of interventions.
- 15.3.3 Describe health promotion models and theories at the interpersonal level that can guide the identification, development, and implementation of interventions.
- 15.3.4 Utilize a theory or model to guide the identification, development, and implementation of interventions.

Various theories and models support the practice of health promotion and disease prevention. These theoretical bases guide the identification, development, and implementation of interventions. In many cases, they explain how health behaviors are influenced or how to influence health behaviors (Rejeski & Fanning, 2019). As such, they are commonly called *behavior change theories* and are geared toward individual health behaviors. However, it is also necessary to look at health promotion from a systems level to encompass the holistic nature of health and all the factors that impact health, or the SDOH, as discussed previously.

Applying a Systems Perspective to Health Promotion

There are different levels of influence that can affect health behavior. Recall Deanna in the case scenario. After receiving the blood pressure reading at the community health screening, Deanna may delay going to her provider for an annual exam. At the intrapersonal (individual) level, Deanna may have been stressed about the blood pressure reading, which she knows may increase her blood pressure even more, so this inaction may be due to fears of what the exam will reveal. At the interpersonal level, Deanna's friends like to engage in regular exercise. This would be a positive factor, encouraging Deanna to participate in healthy activities. At the institutional level, scheduling an appointment may be difficult due to limited office hours. At the public policy level, Deanna may lack insurance coverage and have difficulty affording the appointment's cost. The outcome of the individual avoiding an annual exam and potentially negatively affecting their health may result from every level of influence.

Theories and Models at the Intrapersonal, Interpersonal, and Community Levels

This section examines theories and their applications at the individual (intrapersonal), interpersonal, and community levels of the socio-ecological perspective (see [Socio-Ecological Perspectives and Health](#)). At the intrapersonal and interpersonal levels, these theories can be broadly categorized as **cognitive-behavioral theories**, which have three common concepts (National Cancer Institute, 2005, p. 12):

- Behavior is mediated by cognition. In other words, what people know and think affects how they act.
- Knowledge is necessary for but not sufficient to produce most behavior changes.
- Perceptions, motivations, skills, and the social environment are key influences on behavior.

Community-level models “offer frameworks for implementing multi-dimensional approaches to promote healthy behaviors” (National Cancer Institute, 2005, p. 12) and complement education by providing efforts to change the social and physical environment in hopes of supporting positive behavior changes.

Individual or Intrapersonal Level

The individual level is the most basic level of health promotion and disease prevention. Individual behavior is the most fundamental unit of group behavior; therefore, individual-level (intrapersonal-level) influence is necessary to promote behavior change at the larger levels. **Intrapersonal-level** theories focus on intrapersonal factors, which exist or occur within the individual self or mind. These factors include knowledge, attitudes, beliefs, motivation, self-concept, developmental history, past experiences, and skills.

The health belief model (HBM) focuses on an individual’s perceptions of the threat that a health problem poses, the benefits of avoiding the threat, and the factors that influence the decision to act. The threat could relate to susceptibility or severity, and factors influencing the decision to act could involve barriers, cues to action, or self-efficacy. One of the first theories of health behavior, the HBM was developed in the 1950s through the U.S. Public

Health Service to explain why so few people were participating in free, government-supported programs to prevent and detect disease. The HBM (National Cancer Institute, 2005, p. 13) indicates that an individual is ready to act regarding their health if six constructs are in place (see [Table 15.4](#)).

The six constructs provide a beneficial framework for designing short-term and long-term behavior change strategies in individuals. They can also be used to design or adapt health promotion or disease prevention programs for groups. The HBM may be used alone or in combination with other theories or models.

Construct	Definition	Potential Change Strategies
Perceived susceptibility	Beliefs about the chances of getting a condition	<ul style="list-style-type: none"> Define the population(s) at risk and their levels of risk Tailor risk information based on an individual's characteristics or behaviors Help the individual develop an accurate perception of their own risk
Perceived severity	Beliefs about the seriousness of a condition and its consequences	<ul style="list-style-type: none"> Specify the consequences of a condition and recommend action
Perceived benefits	Beliefs about the effectiveness of taking action to reduce risk or seriousness	<ul style="list-style-type: none"> Explain how, where, and when to take action and the potential positive results of doing so
Perceived barriers	Beliefs about the material and psychological costs of taking action	<ul style="list-style-type: none"> Offer reassurance, incentives, and assistance Correct any misinformation
Cues to action	Factors that activate “readiness to change”	<ul style="list-style-type: none"> Provide “how to” information, promote awareness, and employ reminder systems
Self-efficacy	Confidence in one’s ability to take action	<ul style="list-style-type: none"> Provide training and guidance in performing actions Use progressive goal setting Give verbal reinforcement Demonstrate desired behaviors

TABLE 15.4 The Health Belief Model (HBM) (See National Cancer Institute, 2005.)

Another theory that can be used at the intrapersonal level for health promotion and prevention is the stages of change, or transtheoretical, model. This model is based on the premise that behavior change is a process, not an event, and as a person attempts to change a behavior, they move through five stages: precontemplation, contemplation, preparation, action, and maintenance. For more on these stages, see [Socio-Ecological Perspectives and Health](#). An example of how this model may be applied is the CDC (2017) fact sheet “[Talking about Fall Prevention with Your Patients](#) (<https://openstax.org/r/cdcgovsteadi>)” that describes strategies for matching fall prevention advice to a client’s stage of readiness.

THEORY IN ACTION

The Transtheoretical Model

[Access multimedia content](#) (<https://openstax.org/books/population-health/pages/15-3-theories-and-models>)

The podcast “Lifestyle and Behavior Change” provides a discussion of how to use the Transtheoretical Model when performing health coaching for lifestyle and behavior change.

Listen to the podcast or read the [transcript](#) (<https://openstax.org/r/pchancet>), and then respond to the following questions.

1. Which stage of the transtheoretical model is the focus of the podcast?
2. What are some specific examples of health coaching in public health?

Interpersonal Level

At the interpersonal level, “theories of health behavior assume individuals exist within, and are influenced by, a social environment” (National Cancer Institute, 2005, p. 19). The social environment can include anyone with whom an individual interacts, such as family, friends, coworkers, health professionals, and others. The opinions, thoughts, behaviors, advice, and support of these people influence the individual’s feelings and behavior, and the individual has an equal effect on these people.

Social cognitive theory (SCT) is the most frequently used example of an interpersonal model. SCT describes the influence of experiences, actions of others, and environmental factors on an individual’s health behaviors. Three main factors that affect the likelihood that a person will change a health behavior, according to the SCT, are self-efficacy, goals, and outcome expectancies. SCT includes six constructs, described in [Table 15.5](#).

Construct	Definition	Potential Change Strategies
Reciprocal determinism	The dynamic interaction of the person, behavior, and environment in which the behavior is performed	Consider multiple ways to promote behavior change, including making adjustments to the environment or influencing personal attitudes
Behavioral capacity	Knowledge and skill to perform a given behavior	Promote mastery learning through skills training
Expectations	Anticipated outcomes of a behavior	Model positive outcomes of healthful behavior
Self-efficacy	Confidence in one’s ability to take action and overcome barriers	Approach behavior change in small steps to ensure success and be specific about the desired change
Observational learning (modeling)	Behavioral acquisition that occurs by watching the actions and outcomes of others’ behavior	Offer credible role models who perform the targeted behavior
Reinforcements	Responses to a person’s behavior that increase or decrease the likelihood of recurrence	Promote self-initiated rewards and incentives

TABLE 15.5 Social Cognitive Theory (SCT) (See National Cancer Institute, 2005.)

CONVERSATIONS ABOUT CULTURE

HoMBReS

HoMBReS is a community-based intervention designed to reduce the risk of HIV and other sexually transmitted infections among Latino men living in rural areas of the United States. The program is based on the SCT and trains “navegantes” (navigators) who provide information and risk reduction materials to the target population.

[Read about HoMBReS \(<https://openstax.org/r/ruralhealthinfo>\)](#), and then respond to the following questions:

1. What is the environment in which HoMBReS is delivered?
2. Which construct of SCT does HoMBReS seem to primarily focus on?

Community Level

Communities are at the heart of public health promotion and disease prevention. Community-level models explore how social systems function and change and how to activate community members and organizations. Models using community-level strategies can be used in numerous settings, including health care institutions, schools, workplaces, community groups, and government agencies. These models use the ecological perspective, as described in [Socio-Ecological Perspectives and Health](#), addressing individual, group, institutional, and community issues (National Cancer Institute, 2005).

One of the most frequently used community-level models is the **diffusion of innovations theory**. It addresses how new ideas, products, and social practices spread within an organization, community, or society or from one society to another (National Cancer Institute, 2005). Diffusion of innovations is “the process by which an *innovation* is communicated through certain *channels* over *time* among the members of a *social system*” (National Cancer

Institute, 2005, p. 27). These four central concepts are defined in [Table 15.6](#).

Concept	Definition
Innovation	An idea, object, or practice that is thought to be new by an individual, organization, or community
Communication channels	The means of transmitting the new idea from one person to another
Social system	A group of individuals who together adopt the innovation
Time	How long it takes to adopt the innovation

TABLE 15.6 Concepts in Diffusion of Innovations (See National Cancer Institute, 2005.)

Diffusion of innovations as it relates to health promotion and disease prevention requires a multilevel change process. At the individual or intrapersonal level, adopting a health behavior innovation usually involves lifestyle change. At the organizational or interpersonal level, it may involve starting programs, changing regulations, or altering roles. At the community level, the media, policies, or beginning initiatives may be involved. Considering the attributes that determine how quickly and to what extent an innovation will be adopted and diffused (see [Table 15.7](#)) can help health care professionals position it most effectively.

Attribute	Key Question
Relative advantage	Is the innovation better than what it will replace?
Compatibility	Does the innovation fit with the intended audience?
Complexity	Is the innovation easy to use?
Trialability	Can the innovation be tried before making a decision to adopt?
Observability	Are the results of the innovation observable and easily measurable?

TABLE 15.7 Key Attributes Affecting an Innovation's Diffusion (See National Cancer Institute, 2005.)

The diffusion of innovations theory also involves categories of adopters, seen in [Table 15.8](#). By identifying the characteristics of people in each adopter category, health care professionals can more effectively plan and implement strategies customized to their needs (National Cancer Institute, 2005).

Category of Adopter	Characteristics
Innovators	<ul style="list-style-type: none"> They want to be the first to try the innovation. They are interested in new ideas and challenges and are willing to take risks.
Early Adopters	<ul style="list-style-type: none"> They tend to be opinion leaders in a social system and have influence over the decisions of others. They are already aware of the need for change, so they are comfortable adopting new ideas.
Early Majority	<ul style="list-style-type: none"> They are rarely leaders, but they adopt new ideas before the average person. They typically need to see evidence that the innovation works before they are willing to adopt it.
Late Majority	<ul style="list-style-type: none"> They are skeptical of change. They will adopt an innovation only after the majority has tried it.
Laggards	<ul style="list-style-type: none"> They are very skeptical of change. They are the hardest group to persuade to adopt an innovation.

TABLE 15.8 Adopter Categories in Diffusion of Innovations Theory (See Ohkubo et al., 2015.)

The diffusion of innovations theory combines all of these elements to guide the health care professional in providing health promotion and disease prevention efforts. For example, a local university designs a program for the county

public school system to decrease obesity in elementary school students. In the classroom, students learn about healthy foods, nutrition, and reading nutrition labels. The school cafeteria provides sample lunch menus with nutrition information. In physical education classes, students learn how different physical activities contribute to healthy living. After a few years, the program is considered a success. Program participants continued to have healthier habits than children who graduated before the program began.

The program's success, however, is not enough. To broaden its impact, diffusion is necessary. The program's *relative advantage* could be demonstrated to other school district leaders. The program's *compatibility* could be demonstrated by illustrating how it meets national and state standards for health and physical education. *Complexity* could be addressed with teaching toolkits that make content easily accessible to educators. Interested educators could access free sample teaching materials via a website for *trialability*. Finally, *observability* could be provided via a video on the same website for demonstration purposes. Once adopted by another school district, leadership at the district could use the categories of adopters to roll out the program to educators.

15.4 Barriers and Opportunities for Health Promotion and Disease Prevention

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 15.4.1 Describe barriers that negatively impact health outcomes.
- 15.4.2 Examine factors that influence participation in health promotion activities.
- 15.4.3 Recognize opportunities for health promotion and disease prevention across health care settings.
- 15.4.4 Explain how systems can serve as barriers to effective disease prevention and health promotion.

Many factors influence the health of individuals and communities. A barrier is a circumstance or obstacle that keeps people from progressing toward achieving a positive health outcome. Barriers to health promotion and disease prevention exist at various levels, including the individual level, family level, system level, and community or population level. The health care setting may even present barriers. On the other hand, communities provide many opportunities for health promotion and disease prevention, particularly within health care. Nurses who understand barriers can capitalize on available opportunities.

Barriers to Health Promotion and Disease Prevention

Nurses should be aware of barriers, including barriers to economic stability and those that block access to high-quality education and health care, so they can plan to overcome them for clients or populations. Other barriers relate to neighborhood and built environment and to social and community contexts. These barriers can also contribute to health disparities, as described in [Health Disparities](#). As discussed, the SDOH are barriers that can prevent an individual from obtaining the resources they need to achieve better health outcomes and improved quality of life (Healthcare Information and Management Systems Society, 2020; see [Social Determinants Affecting Health Outcomes](#).) [Table 15.9](#) provides individual and system-level examples of barriers to health promotion and disease prevention that may occur within each area of the SDOH.

Social Determinants of Health (SDOH)	Example of an Individual-Level Barrier	Example of a System-Level Barrier
Economic Stability	A client's primary provider instructs them to follow a low-sodium diet. The client will not receive a paycheck until Friday and only has \$30 for the next 2 days. Rather than choose a salad from the grocery, the client chooses a fast-food meal to make the money they have last longer.	A client who has recently experienced respiratory difficulties lives in a rental apartment in a community with little stable housing. A neighbor reported mold in the building due to frequent water leaks. The client's primary provider is concerned that the apartment may be contributing to the client's respiratory condition. The client can barely afford the apartment and cannot afford to move.
Education Access and Quality	An individual with limited English proficiency has chest pain. Because they are not sure they can describe their symptoms, they choose to rest at home rather than seek health care.	A child is enrolled in a low-quality school with limited health resources, multiple safety concerns, and low teacher support. The child is diagnosed with type 1 diabetes and requires insulin injections twice during the school day. There is no school nurse.
Health Care Access and Quality	A client who does not drive lives in a rural area. She has arranged for her grandchild to drive her to an appointment for a mammogram 2 hours away, but the grandchild's vehicle is unreliable and is not drivable on the day of the appointment.	An urban clinic has experienced a shortage of providers following the COVID-19 pandemic. This has resulted in clients experiencing longer wait times and delayed care.
Neighborhood and Built Environment	A client is diagnosed with obesity and instructed by their primary provider to walk 30 minutes daily. The client lives in an urban area with a high crime rate. The only available walking locations are the city streets and a dimly lit park known for drug dealing and use. The client works 12-hour daytime shifts, so the only time they can walk is after dark.	An older adult client relies on a neighbor to perform weekly grocery shopping. The neighbor does not have a car and walks to the closest nearby store, approximately 1 mile away. The store has no fresh produce and is not a chain supermarket. A convenience store within a gas station is the only other store within walking distance. The client would like fresh fruits and vegetables, but these are unavailable.
Social and Community Context	A transgender teenager is bullied and experiences depression. They experience social rejection and isolation, decreased social support, and verbal abuse daily.	A family of color lives in a neighborhood that has historically been ignored for social improvements. The family's children were all considered small-for-gestational-age births.

TABLE 15.9 SDOH as Barriers to Health Promotion and Disease Prevention

The experience of structural racism results in chronic discrimination, stress, and depression, which has a further negative impact on the ability of those within historically marginalized populations and can create a further barrier to health promotion and disease prevention (Churchwell et al., 2020). One particular form of a barrier to health outcomes has already been discussed in [Structural Racism and Systemic Inequities](#). The COVID-19 pandemic illustrated this point:

- Black, Hispanic, and Latino people; American Indians/Alaska Natives; and Pacific Islanders had a higher COVID-19 morbidity and mortality rate than White people.
- Counties that had over 45 percent of residents belonging to a historically oppressed group recorded higher rates of COVID-19 infection and mortality compared to counties with mostly White residents regardless of the county's poverty level.
- During the pandemic, there was a rise in anxiety and depression. Studies show that Hispanic and Latino adults

(22 percent) and Black adults (18 percent) experienced a higher rate of substance use initiation or increase than White adults (11 percent) during this time (Churchwell et al., 2020).

As individuals and populations encounter these many barriers to health promotion and disease prevention, health outcomes begin to decline. Overcoming these barriers is the only way to successfully achieve positive health outcomes, as an individual or a population.

Barriers to Health Promotion and Disease Prevention Within a Health Care Delivery System

The structure of health care delivery systems is made up of internal and external factors that can influence health promotion and disease prevention, therefore impacting health outcomes. Internal factors include everything within the environment in which health care services are provided as well as the resources required for providing those services. These include, but are not limited to, leadership styles, organizational culture, policies and procedures, and information sharing. External factors include government's role in health care, community expectations and influences, ownership of the health care system, and the extent of services the system provides.

A nurse serving in a role related to health promotion and disease prevention may encounter internal or external barriers from the health care system. The system may lack financial or political support for health promotion implementation. There may be a lack of time for effective health promotion and disease prevention activities, particularly in competition with the day-to-day demands. Poor communication may exist between the various entities within and outside the health care system. Finally, others within the system may lack interest in health promotion and disease prevention (Rogers et al., 2021).

UNFOLDING CASE STUDY

Part B: Health Screening Follow-Up

Read the scenario, and then answer the questions that follow based on all the case information provided in the chapter thus far. This case study is a follow-up to Case Study Part A.

During Deanna's appointment, a nurse working in the primary care provider's office is teaching Deanna about lifestyle modifications to lower her high blood pressure level, such as a low-sodium diet and regular exercise. As the nurse is discussing lifestyle changes with Deanna and answering her questions, the office manager calls the nurse out of the room and asks why they are spending longer than the allotted 15 minutes with the client. The nurse explains that Deanna has many questions about the recommended dietary changes. The manager indicates that the client should be dismissed and instruction can be continued at her follow-up appointment in 2 months.

3. Which of the following is likely correct regarding the office manager?
 - a. They are fostering a culture that values teamwork and collaboration with other departments.
 - b. They are providing equity in time to all clients to decrease the potential for health disparities.
 - c. They do not perceive health promotion and disease prevention as a valuable part of health care.
 - d. They do not have a focus on managing client demand as it relates to the health care system.

 4. Which level of prevention is the nurse using when providing dietary instruction to Deanna?
 - a. Primordial prevention
 - b. Primary prevention
 - c. Secondary prevention
 - d. Tertiary prevention
-

Factors That Influence Participation in Health Promotion Activities

How individuals and populations define health and health problems, and their perception of health's importance, influence any attempts to improve their health through health promotion activities. Three factors either support or form barriers to participation in health promotion activities:

- A **predisposing factor** includes any characteristics of the individual or population that affect personal motivation to bring a change in behavior, including their knowledge, beliefs, values, attitudes, and norms. An

example of a predisposing factor leading to a positive health outcome would be the belief that smoking is harmful to health.

- **Reinforcing factors** occur in the form of positive or negative feedback, such as rewards or punishments, and the influence of a peer, teacher, family, or other person or group perceived as important ([Figure 15.2](#)). Continued receipt of feedback can motivate repetition of behavior. Using the smoking example, a reinforcing factor leading to a negative health outcome would be peer pressure to smoke.
- **Enabling factors** are social and environmental factors that facilitate or motivate attainment of specific behaviors, such as ease of access, availability, health-related laws, resources, and skills. An example of an enabling factor that leads to a negative health outcome would be the easy availability of cigarettes when other members of the family smoke. [Table 15.10](#) provides additional descriptions and examples of these factors.

FIGURE 15.2 Family members attending a graduation ceremony wear masks to prevent the spread of disease during a crowded event, illustrating the reinforcing factors related to following health guidance. (credit: “More Caps & Gowns & Mask” by Phil Roeder/Flickr, CC BY 2.0).

Factors	Description	Examples	
Predisposing factors	Intellectual and emotional “givens” that tend to make individuals or populations more or less likely to adopt a healthy or risky behavior or lifestyle or to approve of or accept particular environmental conditions	Knowledge	A person is more likely to avoid using smokeless tobacco if they know it can lead to cancer.
		Attitudes	People who have participated in athletics as youths tend to see regular exercise as a normal part of life.
		Beliefs	A client may believe that if a food’s label says “low fat,” it is healthy to eat or that premarital sex is a sin, so teenagers should not be provided with condoms.
		Values	A person who values cleanliness is more likely to follow hand hygiene guidelines.

TABLE 15.10 Factors Influencing Participation in Health Promotion

Factors	Description	Examples	
		Confidence	A client may not attempt to follow a weight loss regimen simply because they do not feel they are capable of doing so.
Enabling factors	Internal and external conditions directly related to the issue that help individuals or populations adopt and maintain healthy or unhealthy behaviors or lifestyles, or to embrace or reject particular environmental conditions	Availability of Resources	A person who abuses drugs is more likely to get help if recovery assistance is readily available to them.
		Accessibility of Services	If a specialist has a waiting list over a year long and is located 10 hours away, a client is less likely to agree to their care.
		Community and/or Government Laws/Policies	A person is less likely to drink alcohol if they live in a community that does not sell or serve alcoholic beverages.
		Issue-Related Skills	A person who is very organized and manages their time well will be more likely to stick to a prescribed health regimen.
Reinforcing factors	The people and community attitudes that support or make difficult adopting healthy behaviors or fostering healthy environmental conditions	Largely the attitudes of influential people or groups	A child from a family who supported the use of masks during the COVID-19 pandemic was more likely to wear a mask in public.

TABLE 15.10 Factors Influencing Participation in Health Promotion

Educational interventions can influence some of these factors, while some are not as easily influenced. In the case of reinforcing factors, it may be useful to aim interventions at these influential people and groups to effectively impact an actual target individual or group (The University of Kansas, 2023).

When providing educational interventions, the nurse must also consider the health literacy of individuals. Health literacy involves each person's ability to find, understand, and use health information and services (HHS, 2021). Health literacy will be discussed in more detail in [Assessment, Analysis, and Diagnosis](#).

Opportunities for Health Promotion and Disease Prevention Across Health Care Settings

The Ottawa Charter first introduced the term **health promotion setting**, a place or social context where daily activities and various factors interact to influence health and well-being. Health promotion settings are actively used and shaped to address health-related issues rather than used solely for delivering specific services or programs. Typically, settings have physical boundaries, defined roles for people, and an organizational structure (WHO, 2021b, p. 30). Health promotion settings exist in cities, hospitals, schools, universities and colleges, and workplaces (Kokko & Baybutt, 2022). These are described more in [Table 15.11](#).

Setting	Description	Examples
Health Promotion Cities	Global networks of cities that have come together to engage in health promotion and disease prevention	South-East Asia Healthy Cities Network The Partnership for Healthy Cities
Health Promotion Hospitals	First identified in the 1990s as a way to support hospitals that were beginning to put the Ottawa Charter into practice; now range from implementing one health promotion project, to assigning a specific role or department to health promotion, to playing a large part in promoting the health of the community	The Wellness Institute at Seven Oaks General Hospital in Canada
Health Promotion Schools	Established to enhance health through education and promotion for students, school staff, families, and the community	CDC's Virtual Healthy School that uses the Whole School, Whole Community, Whole Child (WSCC) model
Health Promotion Universities and Colleges	Guided by the 2015 Okanagan Charter, <i>An International Charter for Health Promoting Universities and Colleges</i> , which calls on institutes of higher education to embed health into all aspects of campus culture and to lead health promotion actions and collaboration locally and globally	The University of Alabama at Birmingham Health Promoting University
Health Promotion Workplaces	Provide programs and policies to reduce health risks and improve the quality of life for workers	CDC's Workplace Health Promotion focused on hospital employees' health

TABLE 15.11 Health Promotion Settings (See CDC 2019a, 2019c; The University of Alabama at Birmingham, 2023.)

THE ROOTS OF HEALTH INEQUITIES

Urban Health Inequities

Data on urban health inequities, or disparities in health outcomes among and within cities, has been extensively documented worldwide, spanning countries and regions, irrespective of their economic development and health care infrastructure. These disparities reflect the overarching disparities in the SDOH including economic conditions, education, the physical and built environment, and the quality and accessibility of health care. To promote health equity, nurses must tailor their health promotion and disease prevention efforts to the specific location and the population being served.

(See Freitas et al., 2020.)

Prisons, the digital environment (including social media), and more recently airports, places of worship, and specific coastal communities in the United Kingdom are other identified health promoting settings (Kokko & Baybutt, 2022). Global initiatives to address the health of those who work and live in prisons, particularly in the United Kingdom, have provided benefits from the development of a “whole-prison approach” to health promotion. This approach involves peer support for both workers and incarcerated people, behavior modification initiatives, disease

prevention and screening, easily accessible information about health services and current health campaigns, and a focus on continuity of care (Woodall & Freeman, 2019). This approach has not been adopted in the United States. However, the CDC (2022) does offer recommendations and guidance for correctional settings, including information on infectious disease, COVID-19 management, traumatic brain injury, and other medical problems and conditions.

The WHO (2021a) issued its *Global Strategy on Digital Health 2020–2025* (<https://openstax.org/r/whointdocs>), which provided guiding principles, strategic objectives, a framework for action, and implementation principles for the strategy and action plan related to using digital technologies to shape the future of global health. This strategy incorporates the use of a variety of technologies to create a continuum of care (WHO, 2021a, p. 8). The WHO (2023b) has also convened a panel of experts to address infodemic management and social listening. An **infodemic** is an overabundance of information, including misinformation, that surges during a health emergency. The WHO recognizes that during a health emergency, people seek, receive, process, and act on information differently than in other times, making it even more important to use evidence-based strategies to address health issues. **Social listening** is the process of gathering information about people's questions and concerns and the circulating narratives and misinformation about health from online and offline data sources. This includes data from social media platforms. The WHO (2023b) hopes to provide an ethical framework and tools that can be used for social listening and infodemic management.

▶ HOW TO PROTECT YOURSELF IN THE INFODEMIC

[Access multimedia content \(<https://openstax.org/books/population-health/pages/15-4-barriers-and-opportunities-for-health-promotion-and-disease-prevention>\)](https://openstax.org/books/population-health/pages/15-4-barriers-and-opportunities-for-health-promotion-and-disease-prevention)

Watch this video to learn more about the misinformation that spread during the COVID-19 pandemic, and then respond to the following questions.

1. What are some negative consequences of an infodemic?
2. Do you see any positive aspects of an infodemic? Explain your answer.
3. Name three ways you can protect yourself from an infodemic during a pandemic.

Over 400 airports of various sizes prioritized health and safety during the peak of the COVID-19 pandemic by becoming accredited or participating in the Airports Council International (ACI, 2023) Airport Health Accreditation (AHA) program. These airports, including several in the United States, implemented airport industry best practices to ensure an airport-centric approach to health requirements. Moving forward, the program has moved to the Public Health and Safety Readiness (PHSR) accreditation, which considers a wider range of health emergencies that may lead to air travel concerns (ACI, 2023). A variety of research has also been performed investigating the benefits of health promotion in places of worship (Kwon et al., 2017; Tomalin et al., 2019; Woodard et al., 2020) and determined that faith-based organizations and places of worship can play a vital role in health promotion, particularly for Black, Asian, and minority ethnic communities.

Finally, a setting for health promotion can be even larger than a city. The United Kingdom House of Commons (2022) identified, through a 2021 Chief Medical Officer's report, that English coastal communities have a higher disease burden across physical and mental health conditions as well as lower health outcomes including life expectancy, healthy life expectancy, and disability-free life expectancy. In particular, there are worrying trends in public-health-related outcomes for children and young people. As a result, the Royal College of Physicians and others are encouraging a national strategy to improve the health of these coastal communities.

No consensus exists on a single setting that is best for health promotion. Instead, there are a variety of settings around which individuals and groups live, grow, work, and age that are appropriate for health promotion and disease prevention activities. Settings can be as small as an office and as large as a country, but collaboration and coordination of all entities involved can lead to improvement of health outcomes.

Chapter Summary

15.1 Defining Health Promotion and Disease Prevention

Health promotion and disease prevention are overlapping yet distinct processes that guide the Healthy People 2030 initiative. Best defined by the Ottawa Charter, health promotion is the process of enabling people to increase control over, and to improve, their health. The six dimensions of health promotion behaviors include responsibility, physical activity, nutrition, interpersonal relations, spiritual growth, and stress management. Disease prevention involves undertaking specific interventions geared toward decreasing the burden of disease and its associated risk factors. Preventive care, including screenings, immunizations, check-ups, and counseling, are a large portion of prevention. Nurses play an important role in both health promotion and disease prevention.

15.2 Health Promotion and Disease Prevention Interventions

Nurses select and perform health promotion and disease prevention interventions at the individual and community levels. The nurse can use the five key action areas of the Ottawa Charter for Health Promotion to guide interventions. To appropriately apply interventions, nurses must understand the stages of disease and their corresponding levels of prevention, which can lead to disease risk reduction and prevention of complications of a current disease.

Key Terms

cognitive-behavioral theories theories at the intrapersonal and interpersonal level that share three common concepts: behavior is mediated by cognition, knowledge is necessary for behavior change, and perceptions, motivations, skill, and the social environment influence behavior

Diffusion of Innovations Theory a model for behavior change that addresses how new ideas, products, and social practices spread within an organization, community, or society or from one society to another

disease prevention specific interventions geared toward decreasing the burden of both communicable and noncommunicable diseases and their associated risk factors

enabling factors internal and external conditions that help individuals or populations adopt and maintain healthy or unhealthy behaviors or lifestyle, or embrace or reject particular environmental

15.3 Theories and Models

Nurses and other health care professionals use theoretical models and frameworks to provide appropriate support for health promotion and disease prevention practices at different levels. A variety of theories and models exist at the individual (intrapersonal), interpersonal, and community levels. Prominent models include the socio-ecological perspective, the health belief model (HBM), the stages of change (transtheoretical) model, social cognitive theory (SCT), and diffusion of innovations theory.

15.4 Barriers and Opportunities for Health Promotion and Disease Prevention

Individual- and system-level barriers, described as the social determinants of health (SDOH), influence the health of individuals and communities. The health care delivery system itself poses barriers to health promotion and disease prevention. Predisposing, enabling, and reinforcing factors can be supportive or produce obstacles, and the health care professional must consider these in their efforts to promote health and prevent disease. Health promotion settings include cities, hospitals, schools, universities and colleges, workplaces, and others. Many successful health promotion and disease prevention programs encourage collaboration and coordination across multiple settings.

conditions

health promotion the process of enabling people to increase control over and to improve their health

health promotion setting the place or social context in which people engage in daily activities, in which environmental, organizational, and personal factors interact to affect health and well-being

high-risk approach an approach to prevention that targets prevention only to those who are identified to be at high risk for disease

infodemic an overabundance of information, including misinformation, that surges during a health emergency

intersectoral involving several sectors of society, such as health, education, housing, any level of government, and nongovernmental organizations

intrapersonal-level individual-level

natural history of disease the progression of a disease process in an individual over time

Ottawa Charter for Health Promotion provided a common, socio-ecologic definition of health promotion in 1986

population approach an approach to prevention that implements strategies across an entire population, regardless of individuals' risk levels

predisposing factor intellectual and emotional "givens" that tend to make individuals or populations more or less likely to adopt a healthy or risky behavior or lifestyle or to approve of or accept particular environmental conditions

preventive care routine health care including screenings, check-ups, and counseling to prevent illness, disease, or health-related problems

primary prevention actions aimed at avoiding the effects of disease

primordial prevention actions aimed at preventing the development of risk factors for disease

reinforcing factors the people and community

attitudes that support adopting healthy behaviors or fostering healthy environmental conditions

secondary prevention actions that emphasize early disease detection and target healthy-appearing individuals with subclinical forms of disease

social cognitive theory an interpersonal model for behavior change that describes the influence of experiences, actions of others, and environmental factors on the health behaviors of an individual

social listening the process of gathering information about people's questions and concerns and circulating narratives and misinformation about health from online and offline data sources

tertiary prevention targets both the clinical and outcomes stages of disease; actions are implemented in symptomatic individuals with the aim to reduce the severity of disease and any associated sequelae

Review Questions

- A home health nurse has several clients who live in the same apartment building. In the last week, the nurse has noticed that both elevators in the four-story building are out of order. Two of the clients live on the second floor and use a wheelchair. The nurse leaves a message for the building manager describing their concern for the clients. This action describes the role of the nurse as
 - advocate
 - care provider
 - consultant
 - educator
- Routine bloodwork results indicate that a client has type 2 diabetes. The client does not have any of the symptoms the nurse describes that are common with diabetes. The nurse assesses that this client is in which stage of disease?
 - Clinical
 - Susceptible
 - Subclinical
 - Underlying
- An older individual attends an exercise class in the community's parks and recreation facility at the recommendation of their primary provider. At a follow-up appointment, the client tells the nurse in the primary care office that they are unable to perform several of the exercises due to problems with vertigo and have stopped attending the classes. The nurse determines that the client is experiencing which type of negative enabling factor?
 - Accessibility of services
 - Availability of resources
 - Community and/or government laws/policies
 - Issue-related skills
- An individual who is trying to lose weight is dining out with friends. While looking at the menu, they notice that the restaurant includes calorie content with all menu items. How is this information likely to impact the individual's menu choices?
 - It is a barrier.
 - It is a cue to action.

- c. It is an innovation.
 - d. It is perceived susceptibility.
5. An elementary school nurse has proposed the delivery of a healthy message through the school's audio system every day. The principal thinks this is a new idea that hasn't been tried before, the intercom system is easy to use and readily available, and students tend to listen to the announcements provided. The principal is likely applying which theory or model in making their decision?
- a. The socio-ecological model
 - b. The health belief model
 - c. The transtheoretical model
 - d. The diffusion of innovations theory
6. A public health nurse is working with community members to develop a walking trail to encourage residents to be outdoors and engage in exercise. Which level of prevention is this nurse practicing?
- a. Primordial
 - b. Primary
 - c. Secondary
 - d. Tertiary
7. A community health nurse is developing a community-wide health promotion program to reduce high blood pressure in community members. Which sectors will the nurse need to work with to develop this program?
- a. The health sector only
 - b. The combined roles of multiple sectors
 - c. The health sector and the food and agriculture sector
 - d. Different sectors for each individual
8. A public health nurse is working in a rural community. Community members have expressed concerns about the distance necessary to travel and the time it takes to receive medical care. The nurse collaborates with a hospital in the closest city to establish a mobile clinic that visits the community once a week. What enabling factor did the nurse target to improve population health?
- a. Availability of health care services
 - b. Individual behaviors and lifestyle choices
 - c. Genetic predisposition to disease
 - d. Social and cultural norms
9. A densely populated urban area has a high prevalence of obesity among the residents. The local government is partnering with the health department to build parks and recreation centers to promote physical activity. Which of the following is the most likely system-related barrier the program faces?
- a. Genetic predisposition to obesity
 - b. Lack of community engagement
 - c. Individual client attitudes and beliefs
 - d. Limited financial resources
10. During the COVID-19 pandemic, a public health department wanted to introduce a smartphone application (app) that could track and notify individuals who came into close contact with a confirmed case. However, the department encountered challenges in gaining widespread acceptance and adoption of the new technology. Which concept from the diffusion of innovations theory likely influenced the implementation of the app?
- a. Trialability
 - b. Observability
 - c. Relative advantage
 - d. Compatibility

CHAPTER 16

Creating a Healthy Community

FIGURE 16.1 Each community has unique characteristics that affect the way people live, work, and relax, all of which affect their health.
(credit: modification of work “Students on the beach. It is bright but chilly” by Loren Kerns/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 16.1 The Community as the Client
 - 16.2 What Is a Healthy Community?
 - 16.3 The Nursing Process as a Framework
-

INTRODUCTION Elsa is a 17-year-old high school student with type 1 diabetes mellitus. They play soccer for the school team, babysit for children in the neighborhood most weekend evenings, have worked at an ice cream stand for the past three summers, and see friends from school often. Elsa’s town is on the Atlantic Ocean and is a popular summer destination for people from the surrounding region. The town has plenty of green space and places to jog, bike, and enjoy the outdoors. The community members take pride in keeping the beach clean and wildlife protected. Elsa avoids summer traffic by getting around town on a bike.

The town has many part-time (summer) residents, creating some challenges for the year-round community. The population shrinks from 25,000 summer residents to 1,500 permanent residents each September. From September to May, many stores and restaurants close, especially the smaller, family-owned restaurants with healthier options that rely on tourist traffic to sustain business. Elsa knows plenty of people who feel isolated during the offseason and thinks that substance use is especially problematic during this time. Even some health clinics, dental offices, and pharmacies close, creating problems for residents who need ongoing care. Elsa’s mother has a full-time, year-round job at the grocery store, but some parents do not have consistent work. A special challenge for Elsa is the lack of an endocrinologist or clinic in the area to provide diabetes care, requiring them to travel 90 minutes each way every 3 months for appointments at the nearest hospital with a diabetes clinic. Elsa wishes telehealth visits were an option, but lab testing is required at each visit. A school nurse is helpful with challenges between clinic visits, but

the nurse is only at Elsa's school 2 days a week because the elementary, middle, and high schools all share the nurse.

In community-oriented nursing, nurses may care for groups of people instead of one client at a time. This chapter discusses addressing health in communities, assessing communities, supporting a culture of health, and applying the nursing process to professional practice activities in the community setting. The chapter also provides opportunities to reflect on Elsa's community and the different health opportunities and barriers that community members experience.

16.1 The Community as the Client

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 16.1.1 Explain how the community can serve as the focus of care.
- 16.1.2 Describe a community by location, population, and social systems.
- 16.1.3 Develop a community profile.

Broadly, a **community** is defined as a group of people with at least one characteristic in common. The characteristic may be a place, a personal attribute, or a common goal. In each community, there are individuals with health problems and health risks, some of which may be individual, meaning the rest of the community does not face similar circumstances. For example, a person who smokes or lives in a home with smokers faces increased respiratory health risks compared to a person who does not smoke or live with smokers. A person who does not wear sunscreen has an increased risk of skin cancer compared to a person who applies sunscreen daily. However, every community may house a common health condition or shared health risk. For example, a community situated near a factory that disposes of its toxic chemicals in the water supply shares the risks of consuming contaminated drinking water. Similarly, residents of a city that provides automated external defibrillators (AEDs) in high-traffic public places may have a better chance of surviving a cardiac event than those with no accessible AEDs.

In population- or community-based nursing, nurses work to address a community's collective health instead of individual health needs. Recall the chapter's opening scenario. Try to list five communities that Elsa belongs to.

Community Attributes

Formal and informal communities exist within and across towns and cities. A community may comprise people who celebrate the same cultural holidays or people who are at risk for the same health condition.

Consider the many communities that may be present in a classroom of nursing students: a community of students, a clinical team, a study group, students with children, and perhaps students studying nursing as a new career. Elsa, from the chapter's opening scenario, is a member of numerous communities, including residents of the town, people with type 1 diabetes mellitus, high school students who are gender nonconforming, the soccer team, and residents who get around on bikes, among others. Communities of nursing clients may consist of those who inhabit a specific geographic location, share specific characteristics, or access the same social systems. Communities may also form when groups cannot access select health services and social systems.

Individuals do not have to live within mapped boundaries to be part of a geographic community. People who work, worship, or play in an area where they do not live can be interested in that community's health.

A key activity for geographic communities is civic engagement—involvement in issues of public concern through political and nonpolitical processes that increase community vitality, challenge injustices, and address social problems ([Figure 16.2](#)) (American Psychological Association, 2009; Wray-Lake & Abrams, 2020). Other geographically based communities include members of community centers, such as a Council on Aging or a Boys and Girls Club, and populations of school students, home caregivers, and teachers in a geographic community.

FIGURE 16.2 Protest is a form of civic engagement. Protests can inform members of the public of issues, mobilize voters and community members to act for change, and influence the policy process. Here, people are voicing their opinion on the need to address climate change during a climate strike rally in 2019. (credit: "#ClimateStrike Rally" by MN Senate DFL/Flickr, Public Domain)

HEALTHY PEOPLE 2030

Civic Participation

Social determinants of health and [civic engagement](https://openstax.org/r/healthsoc) (<https://openstax.org/r/healthsoc>) are closely linked. Healthy People 2030 identifies voting, volunteering, participating in group activities and activities such as community gardening, and participating in a recreational sports team as methods of civic participation. Such activities can benefit the health of individuals and populations. Healthy People 2030 aims to increase the proportion of voting-age citizens who vote and increase knowledge of civic activities or interventions that may ameliorate health disparities.

People who share personal characteristics such as race, ethnicity, gender, age, or occupation may create a formal community for mutual support or to advance equitable practices across health care and other fields. Others who share such characteristics may not participate in a formal community but may informally associate with members of the community, remain knowledgeable of the shared successes and challenges the community faces, and advocate for change. Populations of individuals who share health risks may also constitute a community.

Social Media and Other Social Systems

Social media and other social systems provide avenues for the formation and definition of communities. Social and political networks may serve as a basis for uniting as a community for health change. Technology has dramatically enhanced opportunities to join a community, as many people use social networks to participate in civic engagement, learn about health, effect change through sharing stories and knowledge, and organize to advocate for policies and societal changes that advance health. Social media has increased the visibility of community health issues, as community members and advocates can quickly share information with people around the globe.

Advocacy in the context of community health refers to support for a specific health cause or recommendations for community and policy change. Advocacy is a significant health promotion strategy to inform voters and policymakers of pressing community health issues and the consequences of harmful policies or inaction (Jackson et al., 2021). Community members who share their own health experiences encourage the forming of community, as other members who identify with the experiences or want to support health change can join the conversation and become involved. Social media has provided a platform for community members, clinicians, organizations, charities,

and others to connect and work together to improve the **dimensions of community health** in many areas. Health advocates have used social media to call attention to, and impact change for, many issues across the globe, such as alcohol use in the Netherlands, tobacco control in Australia, sexual harassment in Egypt, traffic accidents in Ireland, maternal mortality in the United States, and housing in New Zealand (Albalawi & Sixsmith, 2015; Behm et al., 2022; Bekkers et al., 2011; Chisholm & O'Sullivan, 2017; Hefler et al., 2013; Peuchaud, 2014). [Advocating for Population Health](#) covers nurse advocacy in more detail.

SOCIAL MEDIA AND COMMUNITY HEALTH CHANGE

Communities have worked to generate health change through social media messaging and campaigns. Over the last few years, many social media movements have raised awareness of select health issues, changed public perception of health problems, and even successfully advocated for policy change in companies and organizations or for greater society through changes to public law. For example, the #MeToo movement that went viral in 2017 contributed to the U.S. Congress passing of the Sexual Assault Survivors' Bill of Rights.

Using the social media platform of your choice, explore one of the hashtags below, and then respond to the questions that follow.

- #BlackBreastfeedingWeek
 - #TransHealthMatters
 - #ReclaimingMySize
 - #NativeHealthMatters
 - #NothingAboutUsWithoutUs
 - #MentalHealthAwareness
 - #NotJustSkinDeep
 - #WomensHealthMatters
 - #EveryBodyHasAStory
 - #MedicareForAll
 - #BlackLivesMatter
 - #ThisIsEndometriosis
 - #GirlsCount
 - #HIVNotRetro
 - #FarmworkersFeedUs
 - #TransLivesMatter
 - #HealthEquityNow
 - #QueerAndDisabled
 - #HealthForAll
 - #BreakTheStigma
 - #BlackHealthMatters
 - #SaludLatinx
1. What is the health message or health change that users of the hashtag hope to make?
 2. What are the characteristics of community members amplifying the health message? Are any voices being amplified that would be silenced without social media?
 3. Since the implementation of the hashtag, has any health change occurred? Think about health change locally, statewide, and nationally.

Community Assessments and Profiles

Assessment is the first and most important step of the nursing process. Nurses cannot address a problem if they do not know it exists, and they cannot support a health behavior or community effort if they do not realize it is occurring. Assessment begins with gathering data. Nurses may take several approaches to gathering data. First, they may conduct a **windshield survey**. In a windshield survey, nurses explore a community or neighborhood and observe on foot, from a bench or street corner, or through the windows of a vehicle (Centers for Disease Control and Prevention, 2010). Observations made using this type of survey can alert nurses to urgent or potential health risks in

the community, as observers may notice the condition of sidewalks and public spaces, community noise levels, street access and activity, and the presence or absence of businesses and places of employment. See [Appendix A](#) for an example of a windshield survey template that nurses may use to conduct one of these assessments. Per the University of Kansas Center for Community Health and Development [Community Tool Box](https://openstax.org/r/ctbku) (<https://openstax.org/r/ctbku>) (2023), during such a survey, nurses should observe:

- Housing: age and condition of homes in the neighborhood
- Other buildings: occupancy and accessibility of buildings
- Public spaces: availability of places to gather and their amenities, upkeep, and utilization
- Parks: utilization, times of use, activities facilitated
- Culture and entertainment: presence of museums, libraries, theaters, and sports venues and their accessibility and use by members representative of the full community
- Streetscape: condition of building facades and storefronts, presence of trees and sidewalks, cleanliness
- Street use: presence of people during various times of the day
- Commercial activity: types of businesses, storefront vacancies, stores that provide necessities like groceries
- Signs: languages, level of information
- Industry: types of industry, pollution
- Land use: open space compared to used land; distribution of residential, commercial, and industrial areas
- Infrastructure: condition of roads, bridges, and sidewalks; differences in condition across the community
- Public transportation: presence and use of system
- Traffic: level of traffic, vehicles in traffic
- Environmental quality: green space presence and distribution, air quality, water sources
- Race/ethnicity: characteristics of community, separation or cohesion of groups
- Faith communities: religious institution types and presence
- Health services: hospital and clinic presence and accessibility
- Community and public services: presence of mental health centers, food banks, and housing support and their distribution and accessibility by public transit
- Community safety: police and fire stations
- Public schools: presence of schools and their level of maintenance or upkeep
- Higher education: two- and four-year colleges, location, integration with community versus isolation
- Political activity: political signs (e.g., yard signs during elections), protests, demonstrations
- Community organizations: service clubs and other groups centered on community issues
- Media: local outlets, sponsorship/influence
- Differences among neighborhoods: states of maintenance, presence of community amenities across neighborhoods or sections
- The “feel” of the community: the observer’s overall impression of the community

Regardless of the method they use to conduct a windshield survey, nurses should conduct the survey in pairs or groups. First, it is unsafe to attempt to drive and note observations at the same time. Additionally, each nurse may have different observations, which can add to the richness of data collected. Nurses may also collect data from open sources in the community, such as publicly available reports, census data, and other public documents (Quinn et al., 2019). For example, department of health reports regarding the rates of communicable illnesses and chronic conditions can help elucidate a community’s health needs, and the posted minutes of a local select board meeting can illuminate health topics on the minds of local community partners and residents. See [Assessment, Analysis, and Diagnosis](#) for more information regarding community data sources. Finally, nurses should consult key community partners, policymakers, community leaders, and community members during a community assessment.

THEORY IN ACTION

Windshield Surveys

[Access multimedia content](https://openstax.org/books/population-health/pages/16-1-the-community-as-the-client) (<https://openstax.org/books/population-health/pages/16-1-the-community-as-the-client>)

These two videos were created by nursing students as they conducted their own windshield surveys. The first video displays a windshield survey of a community in Ohio with the students’ interpretation of their observations.

The second video facilitates a virtual windshield survey of communities in Virginia.

Watch both videos, and then respond to the following questions.

1. How do you interpret the windshield survey of communities in Virginia?
2. What other observations would you make of the Virginia communities to prepare a community assessment like the one displayed for the Ohio community?
3. What conclusions might you draw about health and well-being in the Virginia communities based on the windshield survey?

Including community members in community-based nursing work is essential and should start from the earliest stages of a community initiative. Involving community members' perspectives and participation supports not only thorough assessments and meaningful change but also ethical practice. Meaningful partnerships with community members show respect for the community, build trust and relationships, minimize risk and burden, build legitimacy, and positively impact health (Adhikari et al., 2020; Haldane et al., 2019).

Community inclusion also helps nurses work against both the narrative and the reality that clinicians often tell people what to do without considering personal, contextual, social, or other factors. Such actions may be perceived as patronizing and marginalizing the community, or treating them as insignificant and making them feel powerless or unimportant. In nursing, **decolonization** refers to processes that systematically dismantle "western colonial ideologies of superiority, thought, approaches, and privilege" (Fontenot & McMurray, 2020, p. 272). Partnering with members of a community is in alignment with decolonization and can contribute to community interventions that are robust, respectful, culturally responsive, and inclusive (Lin et al., 2020; McCreedy et al., 2018).

THE ROOTS OF HEALTH INEQUITIES

Colonialism in Nursing

Colonialism is an ideology with a strong foundation of control and influence. Nursing students may remember learning about colonists in the contexts of history, war, and geography during primary and secondary school. Depending on the country in which a nursing student attended primary and secondary school, colonists and colonialism may have been depicted as a positive story of starting a new life. However, colonists invade, conquer, occupy, dominate, and exploit the lands of other people. Colonialism and racism, the unfair treatment of individuals based on race, share these harmful foundations. Colonialism and racism are both present in nursing; power dynamics, forced dependency, lack of self-determination, and othering shape nursing education, research, and practice as well as health policy. In community health, nurses must ensure meaningful community participation in community assessments and population health program planning in order to confront racism and colonialism in the discipline.

(See Fontenot & McMurray, 2020; Kimani, 2023.)

Gordon's functional health patterns provide a method of structuring a community assessment and organizing the resulting data (Gordon, 1982). Nurse theorist Marjory Gordon developed the functional health patterns to guide nurses through a thorough assessment of individual clients and families (Gordon, 1982). However, the functional health patterns can also be applied to a community assessment. Ten years after Gordon published her work, nurse scholars Nancy Kriegler and Marilyn Harton used it to develop the community health assessment tool (Kriegler & Harton, 1992). See [Table 16.1](#) for descriptions of the 11 functional health patterns for use in community assessments and the items nurses may assess in each pattern.

Pattern	Community Application	Assessment Items
Health perception–health management	Community provision of health and safety	<ul style="list-style-type: none"> • Public safety, police, fire • Disaster control plan • Safety hazards • Reportable diseases • Death rate—community, for 10 leading causes of death, infant and maternal • Health promotion • Care centers—ambulatory, emergency, inpatient, long-term
Nutritional-metabolic	Community provision of nutritional needs, including education	<ul style="list-style-type: none"> • Public assistance programs • Grocery stores, markets, restaurants
Elimination	Community handling of waste	<ul style="list-style-type: none"> • Water supply • Sewage, trash, garbage, hazardous waste disposal • Recycling programs • Rodent/vermin control • Air and noise pollution
Activity-exercise	Community provision of transportation and recreational opportunities	<ul style="list-style-type: none"> • Work, recreation, and health care transportation • Leisure-time activities across age groups
Cognitive-perceptual	Community decision-making	<ul style="list-style-type: none"> • Government structure and community participation • Key community leaders • Public and private schools, preschools, adult education, higher education • Health education programs • Publications, radio, TV, and information networks
Sleep-rest	Community experience and expression of rhythms and cycles	<ul style="list-style-type: none"> • Types of businesses and industries, hours of operation
Self-perception–self-concept	Community view of itself	<ul style="list-style-type: none"> • Impact of community history on present-day community • Topography, boundaries, area, urban/rural distribution • Population demographics • Occupations, income level, poverty level, unemployment rate, housing types and costs, owner- versus renter-occupied homes

TABLE 16.1 Functional Health Patterns in the Community (See Kriegler & Harton, 1992.)

Pattern	Community Application	Assessment Items
Role-relationship	Community definition of its own role through internal informal and formal relationships and interactions with other communities	<ul style="list-style-type: none"> Relationships within the community and with nearby communities Community-sponsored events, e.g., festivals and parades
Sexuality-reproductive	Community provision of resources and education for reproductive health and family structures	<ul style="list-style-type: none"> Family types and sizes Rates of birth, teen pregnancy Prenatal care Reproductive health care facilities, including abortion providers Reproductive education in schools, parenting classes, childbirth classes
Coping–stress tolerance	Community provision of support services	<ul style="list-style-type: none"> Federal and state assistance programs and use in the community Community-based assistance programs, e.g., support groups
Value-belief	Community addressment of spiritual, cultural, and ethical needs	<ul style="list-style-type: none"> Religious group types, outreach to community, potential impact on community health Social action groups and activities, e.g., programs for unhoused, fundraising for causes, senior citizen programs

TABLE 16.1 Functional Health Patterns in the Community (See Kriegler & Harton, 1992.)

A functional health pattern assessment can help the nurse to develop a community profile that includes identifying health problems, describing health risks, and determining health promotion activities. Recall the chapter's opening scenario. What patterns does the description of Elsa's community address? What questions would the community health nurse have for Elsa and other community members to develop a comprehensive community assessment?

The functional health pattern assessment applies to nursing assessment and practice and can be used during interprofessional community health endeavors. Other tools that may be used include the American Hospital Association's [Community Health Assessment Toolkit](https://openstax.org/r/healthycommunities) (<https://openstax.org/r/healthycommunities>), the CDC's action model, and the CDC's [Community Health Assessment and Group Evaluation \(CHANGE\) tool](https://openstax.org/r/nccdpdnpao) (<https://openstax.org/r/nccdpdnpao>). [Assessment, Analysis, and Diagnosis](#) provides more information on community health assessment tools, models, and frameworks.

CASE REFLECTION

Conducting a Health Pattern Assessment

Read the scenario, and then respond to the questions that follow.

Think back to the chapter's opening scenario. As you get to know Elsa, they share more about the community and their friends with you. You learn that their active schedule does not leave much time for rest, and the same is true for their friends, who also balance jobs, sports, and schoolwork. Elsa sometimes has difficulty fitting it all in each week while getting enough sleep. They also talk about having trouble sleeping during the summer, as seasonal residents and vacationers can be noisy. Elsa feels that they have a manageable workload this week; their only major homework is a health class assignment on sexually transmitted infections. They share that the high school students have a health class meeting every other week, where they discuss health topics such as contraception, exercise, substance use, and relationship safety. Elsa appreciates the school community, which is inclusive and fosters a sense of belonging for the most part, although some students say they don't believe people can have diverse sexual orientation or gender identities, and Elsa wonders if some classmates purposefully misgender them. But the classmates who may be doing this are few, and Elsa's friend group spans all grades, genders, sports, interests, and other characteristics. Elsa thinks your community assessment is interesting, but they are running late to meet up with their friends at the town square for the annual Green Living Festival, which they describe as a giant yard sale of secondhand clothing and household items. The goal of the festival is for these used goods to be repurposed and stay out of the county landfill.

1. With all the information you have gathered from Elsa about the community, which functional health patterns can you describe?
2. What other questions would you like to ask Elsa or their friends about the community so that you could work toward developing a comprehensive community assessment?
3. In your opinion, which functional health pattern is most essential for the public/community health nurse to work to address first?

16.2 What Is a Healthy Community?

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 16.2.1 Identify characteristics of healthy communities.
- 16.2.2 Explain the Robert Wood Johnson Foundation (RWJF) Culture of Health initiative.
- 16.2.3 Describe the Robert Wood Johnson Foundation (RWJF) Culture of Health Action Framework.

A healthy community can support members in achieving their full potential in terms of health, education, community access, employment, and other aspects. The members of a healthy community work collectively to ensure that all can benefit from the offerings and supports present in the community, such as health care, housing resources, nutritionally dense foods, social support, green space, social opportunities, and other factors or attributes of communities that can either contribute to or hinder health and well-being.

The Work of the Robert Wood Johnson Foundation (RWJF)

Robert Wood Johnson II (1893–1968), an American philanthropist, was inspired to support improvements to the American health care system. Having identified shortcomings in the system during his own lifetime care, he felt a strong desire to “help local people down on their luck” (Robert Wood Johnson Foundation, n.d.-a). Johnson recognized the critical role of nurses in quality care. Two of his original goals were to give nurses a greater say in patient care and to professionalize nursing (Robert Wood Johnson Foundation, n.d.-a). These goals continue to guide much of the work supported by the Robert Wood Johnson Foundation (RWJF) in promoting health equity, eliminating health disparities, and supporting the development of communities where all members have an equal opportunity to achieve the highest level of health.

The RWJF Culture of Health Initiative

Since 2013, the RWJF has focused on a Culture of Health initiative to improve population health, well-being, and equity in America (Chandra et al., 2017). To work toward national health equity, the RWJF identified 10 principles key to facilitating a culture of health.

THE ROBERT WOOD JOHNSON FOUNDATION'S 10 PRINCIPLES OF A CULTURE OF HEALTH

- Every individual, family, and community is seen as deserving of health and well-being.
- Health is considered a shared responsibility within our society.
- America's national narrative acknowledges that health and well-being are impacted by injustice, systemic racism, and inequities in social and economic conditions.
- Everyone, no matter their background, has access to the resources they need to create conditions that support good health and well-being.
- All families—no matter who they are, where they live, or how much money they make—should have the resources they need to help their children grow up healthy.
- Health care, public health, and social services work together to fully address the goals and needs of the people they serve.
- Public policy and decision-making in the private industry are guided by the goal of ensuring everyone has a fair and just opportunity for health and well-being
- Communities, regardless of income or geography, have the power, agency, and resources to create and implement their own solutions to the unique health issues facing them.
- Health data, research, and measures prioritize collecting information by race, age, ethnicity, sex, geographic region, and other relevant factors to advance health equity for all.
- No one is excluded.

(See RWJF, n.d.-b)

The RWJF also operates under the knowledge that health is not just the result of individual choices and behaviors and that social, economic, environmental, and other factors interact in complex ways to shape the health of individuals and communities. To that end, the RWJF Culture of Health initiative focuses on community-based determinants of health such as care access, economic stability, housing, and food, as opposed to health interventions for specific disorders and conditions.

The RWJF Culture of Health Action Framework

Community involvement and mobilization play a large role in advancing the RWJF Culture of Health initiative. The organization has built an action framework so that efforts addressing the varied and complex factors that affect health in America may be evaluated efficiently to allow program revision or change in support of meaningful improvement (Li & Pagán, 2016). The Culture of Health Action Framework is used to identify and organize priorities under four distinct action areas (RWJF, 2018):

- Making health a shared value
- Fostering cross-sector collaboration to improve well-being
- Creating healthier, more equitable communities
- Strengthening integration of health services and systems

Making health a shared value means that society must commit to implementing social systems and power structures that allow all individuals and groups to access good health care (Chandra et al., 2016). Mindset and expectations, sense of community, and civic engagement are noted as three drivers of change toward making health a shared value, which can be measured by aspects such as internet searches for health-promoting information and volunteer participation and voter turnout in specific communities (RWJF, 2018).

Fostering cross-sector collaboration to improve well-being means encouraging or incentivizing organizations outside of those traditionally or directly associated with health care (e.g., transportation and housing) to work together to support better health across communities. Because societal barriers to health are beyond the control of individuals and disproportionately impact some groups more than others, health is the responsibility of communities, care systems, businesses, and other organizations across sectors and classes (Tan et al., 2019). Effective collaborations can have lasting impact on health equity and community well-being, and involvement of sectors outside of health care is central to comprehensive health promotion (Towe et al., 2016). Measurements and exemplars of hospital partnerships, business leadership in health, support for working families, and collaboration among communities and

law enforcement agencies can indicate progress in this action area (RWJF, 2018).

Creating healthier, more equitable communities can occur through sustained changes to health policy that support healthful physical spaces, increased access to resources, and changes in cultural norms related to health (Dubowitz et al., 2016). The built and physical environments, social and economic environments, and policy and governance models of communities can support health and equity across communities. The RWJF (2018) identifies community walkability, public libraries, youth safety, housing affordability, residential segregation, early childhood education enrollment, climate adaptation and mitigation, and air quality as measures for determining positive change toward healthier and more equitable communities ([Figure 16.3](#)).

FIGURE 16.3 Public libraries are a community structure offering many health supports to all members of a community. This photo shows a children's library room, where kids and families can spend time reading, playing, and learning for free. Public libraries host community events, many of which are health-focused. (credit: "Children's Room Visitors" by NPL Newburyport Public Library/Flickr, CC BY 2.0)

Finally, *strengthening integration of health services and systems* refers to creating a revised system of health care in the United States that involves interaction among medical care, public health, and social services. Such interactions help maximize health and well-being, ensure equal access and opportunity to achieve health, and increase client engagement, shared decision-making, and transparency in the health setting (Martin et al., 2016). With the effective implementation of Culture of Health initiatives, communities should see increased access to comprehensive public health services, health insurance coverage, and routine dental care (RWJF, 2018).

THE ROOTS OF HEALTH INEQUITIES

Full Scope of Practice

"Full scope of practice for nurse practitioners" is noted by the RWJF as one measure of strengthening integration of health services and systems (RWJF, 2018). Full-scope-of-practice policies permit nurse practitioners to prescribe, diagnose, and treat clients without physician oversight. Nurse practitioners who can work independently at their full scope of practice can establish clinics without needing a physician partner.

Rural populations do not have equity in primary care access. While clinician presence in rural communities is increasing, it is not keeping pace with that of urban communities or meeting the needs of rural populations (Zhang et al., 2020). Full scope of practice for nurse practitioners can advance health equity through offering health care services to areas with shortages of primary care services.

(See RWJF, 2018; Xue et al., 2018; Zhang et al., 2020.)

[Table 16.2](#) lists examples of how different organizations can contribute to the four Culture of Health Action Framework areas RWJF promotes. View the table and consider how nurses could work with community members and agencies to promote a culture of health.

Action Framework Area	Sector/Community Partner	Sample Actions
Making health a shared value	Community organization	Equip members to share messages about the importance of health care with others in the community.
	Hospital	Support messaging for health and well-being, not just health care.
	Mayor's office	Make speeches and deliver other communications that highlight health issues in traditionally "non-health" areas such as transportation and housing.
	Business	Communicate corporate values and describe how they align with well-being in the United States.
Fostering cross-sector collaboration to improve well-being	Community organization	Build relationships with other organizations in the community to prioritize health.
	Local/state public health department	Strengthen connections with businesses to expand health, safety, and well-being.
	Business	Donate to programs that are working to improve health and well-being.
Creating healthier, more equitable communities	Community organization	Strengthen community services that promote well-being, such as libraries and green spaces.
	Local/state public health department	Develop policies and plans that support health efforts.
	Hospital	Ensure the health and well-being of staff.
	Mayor's office	Collaborate with economically depressed neighborhoods to revitalize without gentrifying.
	Business	Provide volunteer opportunities for employees to serve the community in which the company is located.
Strengthening integration of health services and systems	Community organization	Work with health care systems to connect services provided by area nonprofits.

TABLE 16.2 Culture of Health Contributions (See RWJF, 2018.)

Action Framework Area	Sector/Community Partner	Sample Actions
	Hospital	Improve the client experience through inclusive language and literacy. Promote access to all types of care for everyone.
	Business	Provide employees access to quality health, dental, mental health, and substance use disorder treatment.

TABLE 16.2 Culture of Health Contributions (See RWJF, 2018.)

16.3 The Nursing Process as a Framework

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 16.3.1 Explain how the nursing process serves as a framework to gain a holistic perspective of the community and population.
- 16.3.2 Describe how the nursing process can serve as a framework to plan evidence-based nursing interventions.

Nurses use the **nursing process** to deliver care in a systematic and personalized way to individuals and communities through scientific reasoning, problem-solving, and critical thinking (Lotfi et al., 2020; Wagoro & Rakuom, 2015).

The nursing process has five stages:

- Assessment
- Diagnosis
- Planning
- Implementation
- Evaluation

These stages may appear familiar from foundational nursing courses where they would have been applied to physical assessment or care planning across client populations. Defining each stage and applying it to Elsa's community provides a practical framework for understanding how nurses might organize community care in each stage.

Through an *assessment*, the nurse collects data about the community. As discussed, the nurse may collect data through a windshield survey, informant interviews, or publicly available data. Specific evidence collected could include community characteristics, health behaviors, and social determinants of health.

- The population of Elsa's community significantly decreases when the summer residents leave. The closure of stores, restaurants, health clinics, dental offices, and pharmacies during the offseason makes it difficult for year-round community members to access essential items and health services. Some community members feel isolated during the offseason, contributing to mental health concerns and increased substance use. The lack of an endocrinologist or clinic that can address Elsa's diabetes requires them to travel long distances for appointments, and Elsa and their classmates do not have all-day, everyday access to a school nurse.

Through *diagnosis*, the nurse analyzes the data collected to identify areas of opportunity in the community in the context of health. The nurse identifies patterns, trends, or key problems in the data that point to a need for intervention in order to improve health.

- The community health nurse determines that there is limited access to health care across the continuum for community members. There is also an increased risk of social isolation and mental health concerns, which peaks during the offseason but can impact health and well-being year-round. There is a specific lack of diabetes care. School students may not have access to chronic disease management and treatment of

episodic concerns during the school day.

The *planning* stage involves determining goals or desired outcomes of community interventions and developing a plan to progress toward those goals. Community-based interventions could be as local as day-long health fairs or as broad as policy work that changes a population's health care.

- The community health nurse may plan to increase the availability of telehealth services to address the lack of health care access during the offseason. The nurse would collaborate with area physicians, nurse practitioners, and other clinicians to determine the feasibility of offering telehealth services. The community health nurse may also plan to explore possibilities for increased funding for school nurse positions so that the community's students can access a qualified health care professional during the school day. The nurse would discuss the challenges of limited school nurse staffing with current nurses, teachers, students, and families and share the information with the local school board. The nurse may also plan to develop support networks and engaging events for community members facing isolation during the offseason. They would work with community members to identify events likely to draw a crowd and find space to host engaging events.

In the *implementation* phase, the nurse carries out a health program.

- The community health nurse establishes a telehealth clinic at the community center, where every day of the week during the offseason, at least one of the summertime health care providers provides telehealth services to community members. The community health nurse advocates for school nurse support with local community decision-makers and the school committee and can secure funding to double the number of school nurse positions for the public schools. The nurse also organizes community events for different age groups throughout the month, including events for families with infants and young children, meetings for teens, and breakfast groups for seniors.

Finally, the nurse collects additional data to determine progress toward the identified goals and outcomes following a community program or intervention. This *evaluation* helps the nurse make evidence-based decisions regarding whether the program is meeting the community's health needs or requires modification.

- Tracking the number of residents who engage in a telehealth visit may be one method of evaluation. Additionally, due to the availability of primary and chronic care services via telemedicine, the community health nurse may determine whether visit volumes were any lower at urgent care centers and emergency departments. The community health nurse can track these same measures in relation to student health and the presence of a school nurse. The nurse could also track attendance at the new community events and survey attendees on their feelings of isolation and whether they are feeling down, depressed, or anxious.

THEORY IN ACTION

HI-5 Initiative

The nursing process steps and activities that support the health of the community and broader population health goals align with the CDC's Health Impact in 5 Years ([HI-5 \(https://openstax.org/r/cdcpolicy\)](https://openstax.org/r/cdcpolicy)) initiative. This initiative aims to support community health interventions that have positive health impacts, demonstrate results within 5 years, are cost-effective, and offer cost savings. Interventions of this program have contributed to ameliorating a variety of pressing community health concerns.

Visit the website to review this initiative, select an HI-5 intervention that interests you most, and then respond to the following questions.

[School-Based Programs to Increase Physical Activity \(https://openstax.org/r/cdcphy\)](https://openstax.org/r/cdcphy)

[School-Based Violence Prevention \(https://openstax.org/r/cdchi5\)](https://openstax.org/r/cdchi5)

[Safe Routes to School \(https://openstax.org/r/cdcsaferoutes\)](https://openstax.org/r/cdcsaferoutes)

[Motorcycle Injury Prevention \(https://openstax.org/r/cdcmotorcy\)](https://openstax.org/r/cdcmotorcy)

[Tobacco Control Interventions \(https://openstax.org/r/cdctobacco\)](https://openstax.org/r/cdctobacco)

[Access to Clean Syringes \(https://openstax.org/r/cleansyringes\)](https://openstax.org/r/cleansyringes)

[Pricing Strategies for Alcohol Products \(https://openstax.org/r/cdcalcoholpricing\)](https://openstax.org/r/cdcalcoholpricing)

[Multi-Component Worksite Obesity Prevention \(https://openstax.org/r/cdcworksite\)](https://openstax.org/r/cdcworksite)

[Early Childhood Education \(https://openstax.org/r/cdcchildhoodeducation\)](https://openstax.org/r/cdcchildhoodeducation)

[Cleaner and Alternative Fuel Bus Fleets \(https://openstax.org/r/cdccleandiesel\)](https://openstax.org/r/cdccleandiesel)

[Public Transportation System: Introduction or Expansion \(https://openstax.org/r/cdcpublictransportation\)](https://openstax.org/r/cdcpublictransportation)

[Home Improvement Loans and Grants \(https://openstax.org/r/cdchomeimprovement\)](https://openstax.org/r/cdchomeimprovement)

[Earned Income Tax Credits \(https://openstax.org/r/cdctaxcredits\)](https://openstax.org/r/cdctaxcredits)

[Water Fluoridation \(https://openstax.org/r/cdcwaterfluoridation\)](https://openstax.org/r/cdcwaterfluoridation)

1. How does the intervention you selected support the HI-5 initiative?
2. How could a public/community health nurse carry out this program in another community or population? Would the intervention need modification to be successful in a different type of community, such as a rural area, a city with a large population of older adults, or a community with a large refugee population?
3. Ideally, the programs will be sustainable beyond 5 years. What do you think is needed to sustain the program you read about?

Nursing practices that have the goal of healing the whole person are consistent with holistic nursing (Thornton, 2019). Holism is the concept that all parts of a whole are interconnected and do not exist or function without each other. This concept is easily applicable to community-based nursing, as a thorough understanding of the many barriers and facilitators of health in each community is needed to plan effective and appropriate interventions. Nurses can best address the needs of the community and partner with the community when a thorough assessment of the following has been performed:

- Health services
- Community priorities
- Health risks
- Local policies and practices
- Other aspects of the dimensions of community health

In addition to guiding clinical care and use of evidence-based practices, the nursing process guides the work of nurses in the community. Using the nursing process to guide community practice supports a systematic approach to completing work in a holistic manner. Assessment of community needs, development of care plans specific to the community, and implementation of health-promoting interventions that address the community's unique health resources, concerns, and needs are possible through the holistic approach that the nursing process facilitates.

Chapter Summary

16.1 The Community as the Client

When the community is the client, nurses address the community's collective health instead of the acute and chronic health needs of individual clients. Community health nurses focus on promoting health, reducing risk, ameliorating disparities, and increasing equity. Communities may consist of groups of residents in a geographic area or groups of people sharing common characteristics. Nurses use many approaches, such as windshield surveys, to identify community health risks. Nurses should also consult public reports and other open information sources and interview community partners, decision-makers, and community members to ensure accurate assessments and meaningful data and to facilitate ethical practice. Partnerships with community members build trust, convey respect, minimize risk, and contribute to positive health outcomes. Inclusive practices in community-based work align with the concept of decolonization in nursing.

16.2 What Is a Healthy Community?

Communities can work together to support achievement of full health potential in terms of

Key Terms

advocacy support for a specific health cause or recommendations for community or policy change

community a group of people with at least one characteristic in common

decolonization processes that systematically dismantle colonial ideologies of superiority, thought, approaches, and privilege

dimensions of community health the people (also known as status), structures, and processes that may be assessed and measured to determine the care delivery and health outcomes of a community

physical health, mental health, education, community access, employment, and other aspects essential to wellness. The Robert Wood Johnson Foundation (RWJF) supports community health, health equity, and eliminating disparities. The RWJF Culture of Health initiative focuses on community-based health determinants such as access to care, housing, food, and economic stability. While clinical interventions and condition-specific nursing care are important, this kind of care is insufficient to achieve health equity. Focusing on social, economic, and environmental factors is imperative to creating healthy communities.

16.3 The Nursing Process as a Framework

The stages of the nursing process as a framework are assessment, diagnosis, planning, implementation, and evaluation. Nurses can use this framework in community health to guide scientific reasoning, problem-solving, and critical thinking when determining the need for community-level interventions. Holistic approaches to community health practices are based on recognizing that the dimensions of community health are interconnected and interact in complex ways.

nursing process a guiding framework for nurses to deliver care in a systematic and personalized way to individuals and communities through scientific reasoning, problem-solving, and critical thinking; involves five stages: assessment, diagnosis, planning, implementation, and evaluation

windshield survey a method of direct observation in which the nurse views the community or neighborhood while driving around and looking through the windows of the vehicle

Review Questions

1. Which action is an example of the community health nurse engaged in nursing the community as the client?
 - a. Providing individualized care for multiple patients with a specific chronic illness
 - b. Conducting health screenings for individuals in a specific town or city
 - c. Administering vaccines to individuals at high risk of disease complications
 - d. Treating a client's acute illness in a hospital setting

2. Which activity would the nurse recognize as meeting the Healthy People 2030 goal of civic participation?
 - a. Voting in local, state, and federal elections
 - b. Planting a home garden
 - c. Running in a 5-mile road race
 - d. Keeping vaccinations current

3. Which of the following explains why community health nurses should involve community members in assessment processes?
 - a. To allow the community to make improvements prior to a windshield survey
 - b. To share the workload of change with the community members
 - c. To increase the likelihood of community participation in interventions and programs
 - d. To exert control over the community members
4. When developing a community profile guided by Gordon's functional health patterns, which of the following patterns would the nurse identify as focusing on the community's view of itself?
 - a. Cognitive-perceptual
 - b. Health perception–health management
 - c. Nutritional-metabolic
 - d. Self-perception–self-concept
5. Which phase of the nursing process is the community health nurse performing when they identify patterns and trends in data?
 - a. Assessment
 - b. Diagnosis
 - c. Planning
 - d. Evaluation
6. Using the Robert Wood Johnson Foundation's Culture of Health Action Framework, which action would the nurse take when engaged in cross-sector collaboration to reduce overdose deaths in adolescents?
 - a. Encouraging community members to vote on a referendum for substance misuse education
 - b. Working with schools and law enforcement to reduce drug overdoses
 - c. Supporting research for substance misuse prevention programs
 - d. Creating community-based substance misuse treatment programs
7. According to the Robert Wood Johnson Foundation's Culture of Health Action Framework, which action is a driver of change in making health a shared value?
 - a. Increasing partnerships between hospitals
 - b. Supporting working parents
 - c. Providing access to routine dental and vision care
 - d. Changing the mindset and expectations of a community
8. How does the first step of the nursing process inform community health interventions?
 - a. Assessment provides the nurse with data to identify patterns, trends, or key health problems.
 - b. Planning determines the goals or outcomes of possible community interventions.
 - c. Implementation allows for the use of evidence-based practices.
 - d. Evaluation informs the nurse of needed changes to community health programs.
9. Which of the following best describes the concept of holism in community-based nursing?
 - a. Focuses on the physical health of individuals living in the community
 - b. Treats hospitals and clinics, transportation, food stores, and green space as separate entities
 - c. Recognizes the interconnectedness of community policies, health risks, and medical services
 - d. Implements evidence-based practices for the needs and wants of specific communities
10. Which of Gordon's functional health patterns is the nurse assessing by looking at community disaster plans and public safety?
 - a. Coping–stress tolerance
 - b. Health perception–health management
 - c. Value-belief
 - d. Role-relationship

CHAPTER 17

Assessment, Analysis, and Diagnosis

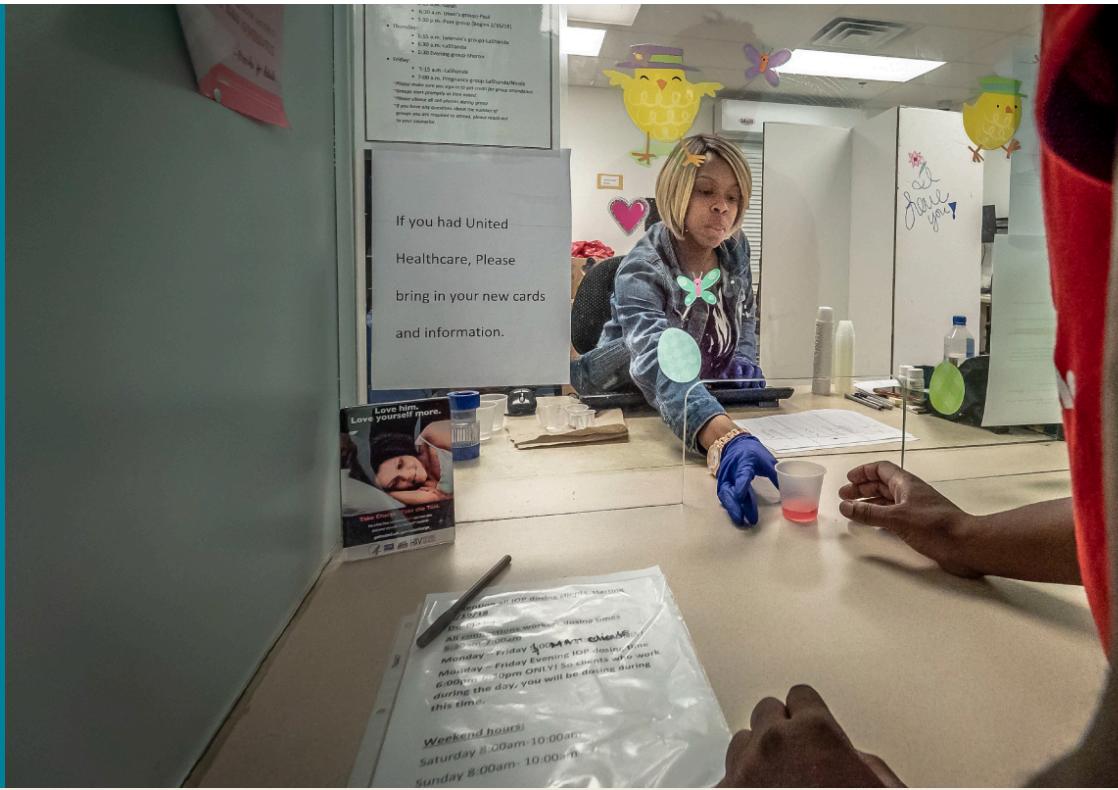

FIGURE 17.1 Community health nurses work directly with individuals, families, and communities to provide health promotion and disease prevention programs. (credit: modification of work by Preston Keres/USDA/Flickr, Public Domain)

CHAPTER OUTLINE

- 17.1 Assessment Tools and Application to Practice
- 17.2 Assessment of Individual and Community Needs for Health Education
- 17.3 Analyzing Population Health Data and Identifying Patterns
- 17.4 Formulating a Nursing Community Diagnosis and Plan of Care

INTRODUCTION For the seventh year in a row, the U.S. Department of Health and Human Services (USDHHS) (2023) has declared the opioid crisis a national public health emergency. Tia, a community health nurse who has just relocated to work at a community health clinic, wonders how this national crisis affects the local community. Tia has several informal conversations with local community organizations. The county emergency medical services (EMS) coordinator tells Tia that drug overdoses from opioids, especially heroin, have increased over the past few months. The director of the withdrawal center explains that they have seen an increased need in individuals seeking daily methadone doses. Tia realizes she must gain a broader understanding of the opioid problem to determine if and which resources are needed to combat the opioid crisis within her community.

Community health nurses like Tia may be charged with leading community health assessment and developing a community health care plan. Assessment, analysis, and diagnosis/planning follow the same principles for communities as in the nursing process for individuals. Collaboration with community partners is a key element of the community nursing process to ensure a community-centered approach. The process identifies a community's health needs to ultimately create a plan to empower communities to focus on health promotion and disease prevention.

17.1 Assessment Tools and Application to Practice

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 17.1.1 Differentiate among assessment tools and data sources (primary and secondary) used to evaluate the health status of populations, communities, and systems.
- 17.1.2 Use a wide variety of sources and methods to access public health information.
- 17.1.3 Conduct a community needs assessment considering self-resilient capabilities of a target population to identify and prioritize problems and health concerns.

Nurses gain a broad understanding of health issues during assessment and analysis. During assessment of an individual, the nurse gathers information about a client's health condition and includes data from primary sources (head-to-toe assessment, client interview) and secondary sources (previous medical records, health professionals, family, or friends). Comparably, assessment of populations is termed **community health assessment** (CHA), or community health needs assessment (CHNA). In this instance, the *client* is the defined population or community. Nurses and other health care professionals use a comprehensive, systematic approach to gather community health data with the primary goal of implementing programs to benefit people in an area as a whole.

A CHA provides a comprehensive picture of a community's current health status, identifying factors contributing to higher health risks or poorer health outcomes and available community resources to improve health (Public Health Accreditation Board [PHAB], 2022). The purpose of community health assessment and a subsequent community health improvement plan is to identify a community's key health needs and address them through strategic intervention. Systematic processes are utilized to collect data, identify and analyze community health needs and assets, prioritize those needs, and provide a foundation for decision-making to implement a plan to address unmet needs (Centers for Disease Control and Prevention [CDC], 2023).

A CHA's timing varies depending on the community's needs. For example, public health departments seeking or maintaining PHAB accreditation must complete a community health assessment every 5 years. Some communities choose to conduct a CHA more often due to policy mandates. For example, the Affordable Care Act (ACA) requires nonprofit hospitals to conduct a CHA every 3 years. Communities may also conduct a partial or full CHA as needed. As noted in the chapter introduction, Tia wonders how the opioid crisis impacts the local community. To understand this issue clearly, Tia can conduct a partial CHA focusing on the opioid crisis. If a larger CHA is in process or was completed recently, such as within the past year, Tia can extract the data regarding drug use and overdose.

Community Health Assessment Models, Frameworks, and Tools

CHA models, frameworks, and tools guide community assessment and community health improvement. They provide a systematic, evidence-based process for organizing the assessment team; collecting and analyzing data; and planning, implementing, and evaluating community health improvement strategies. Most assessment and planning frameworks contain common actions. According to the CDC (2023), common elements of assessment and planning frameworks include the following:

- Organize and plan
- Engage the community
- Develop a goal or vision
- Conduct community health assessment(s)
- Prioritize health issues
- Develop a community health improvement plan
- Implement and monitor the community health improvement plan
- Evaluation process and outcomes

These common actions are evident within the frequently used CHA models, frameworks, and tools described in this chapter. This section reviews the Community Health Assessment toolkit, the Mobilizing for Action through Planning and Partnerships (MAPP) framework, the Community Health Assessment and Group Evaluation (CHANGE) tool, the PRECEDE-PROCEED model, and the Agency for Toxic Substances and Disease Registry (ATSDR) action model.

Community Health Assessment Toolkit

The American Hospital Association (AHA) developed the Association for Community Health Improvement Community Health Assessment toolkit to help nonprofit hospitals comply with Internal Revenue Service regulations for CHAs. The toolkit consists of nine steps for conducting a CHA and developing intervention strategies (AHA, 2017).

The [Community Health Assessment Toolkit \(<https://openstax.org/r/healthycommunities>\)](https://openstax.org/r/healthycommunities) identifies community engagement as a central component of the CHA process. **Community engagement** is the process of working collaboratively with and through groups of people to identify the health needs of community residents and strategies to address them. To engage the community, the nurse must invite community partners to participate. **Community partners**, also called stakeholders, are all persons, agencies, and organizations that have an investment in the community's health and in the local public health system (National Association of County and City Health Officials [NACCHO], 2016). This includes community members who benefit from health services and those that provide health services, such as informal or formal leaders from schools, faith-based organizations, businesses, social clubs, health care, transportation, and government. Community members may decide to establish a **partnership**, a relationship characterized by mutual cooperation and responsibilities among individuals and groups ([Figure 17.2](#)) (NACCHO, 2016). Partnerships may expand into **coalition** building. A coalition is a group of people and organizations that work to address community needs and solve community problems (PHAB, 2022). [Planning Health Promotion and Disease Prevention Interventions](#) further describes partnerships and coalitions.

FIGURE 17.2 Community partnerships include community members who benefit from health services and those that provide health services, such as seen in this town meeting at a health center in Maryland. (credit: "Zeta Center for Health and Active Aging Town Meeting" by James W. Brown/Flickr, CC BY 2.0)

Community engagement strengthens the CHA by including diverse perspectives; increasing collaboration and stronger partnerships; sharing a sense of ownership and resources; and improving communication among individuals from the community, community partner organizations, and hospitals. The Community Health Assessment toolkit enhances community engagement by establishing committees that collaborate at each step. Users of this toolkit sequentially follow the nine steps described in [Table 17.1](#).

Community Health Assessment Toolkit Steps	Actions
Step 1: Reflect and Strategize	<ul style="list-style-type: none"> Review the previous CHA. Identify leadership. Create the assessment team. Identify and procure resources, including budget planning.
Step 2: Identify and Engage Community Partners	<ul style="list-style-type: none"> Connect with community partners from various sectors to ensure diverse perspectives. Identify community members from populations that have increased risk for health disparities.
Step 3: Define the Community	<ul style="list-style-type: none"> Describe the geographic community. Identify community groups, including populations of interest, such as underserved populations.
Step 4: Collect and Analyze Data	<ul style="list-style-type: none"> Collect quantitative and qualitative data to comprehensively describe community indicators and factors that impact health. Attain an overall picture of community health status and highlight the needs of populations within the community, such as populations that experience health inequities. Analyze data.
Step 5: Prioritize Community Health Issues	<ul style="list-style-type: none"> Prioritize community health needs based on severity and magnitude, the community's capacity to act, the availability of resources, and the needs of vulnerable populations.
Step 6: Document and Communicate Results	<ul style="list-style-type: none"> Communicate results of the CHA and convey priorities to community members and identified partners.
Step 7: Plan Implementation Strategies	<ul style="list-style-type: none"> Develop evidence-based, far-reaching strategies that utilize strategic partnerships and available resources to target identified health priorities and populations. Set goals and objectives of the community health improvement plan.
Step 8: Implement Strategies	<ul style="list-style-type: none"> Develop an action plan that details specific activities, accountability, and timelines to guide implementation. Put planned strategies into action. Modify programs and activities, if needed, to address logistical, community partner, and budgetary concerns.
Step 9: Evaluate Progress	<ul style="list-style-type: none"> Evaluate goals, objectives, and strategies. Begin the CHA process again. Compare current data to previous data and determine whether the implemented strategies worked to improve community health outcomes.

TABLE 17.1 Steps in the Community Health Assessment Toolkit

THEORY IN ACTION

Community Health Needs Assessment

[Access multimedia content \(<https://openstax.org/books/population-health/pages/17-1-assessment-tools-and-application-to-practice>\)](https://openstax.org/books/population-health/pages/17-1-assessment-tools-and-application-to-practice)

Conducting community health assessment through collaborative partnerships can positively impact the overall process. This video features key team members from two competing health systems and Penn State Hershey, an academic medical center, who participated in a Community Health Needs Assessment in Pennsylvania.

Watch the video, and then respond to the following questions.

1. Why is it important to conduct a CHNA?
2. What are the benefits of establishing collaborative partnerships to conduct a CHNA?
3. What are the goals of a CHNA according to the speakers in the video?

Mobilizing for Action through Planning and Partnerships

Public health leaders can use the [Mobilizing for Action through Planning and Partnerships \(MAPP\) framework \(<https://openstax.org/r/nacchoorguploads>\)](https://openstax.org/r/nacchoorguploads) for local-level community health improvement planning. The MAPP framework is community-driven and facilitates prioritizing public health issues and identifying resources to address them (NACCHO, 2023). MAPP emphasizes community engagement and collaboration for system-level planning. Originally consisting of six steps, the framework is undergoing redesign (NACCHO, 2020). The redesign includes the foundational principles of equity, inclusion, trusted relationships, community power, strategic collaborations, data-informed action, flexibility, and continuous improvement. The revised MAPP, shown in [Table 17.2](#), provides a streamlined approach to community health assessment and community improvement and directs the nurse and program team through three phases consisting of multiple activities (NACCHO, 2023).

Phases	Activities Completed
1	Build the Community Health Improvement (CHI) Infrastructure
2	Tell the Community Story
3	Continuously Improve the Community

TABLE 17.2 The Revised MAPP Phases

Community Health Assessment and Group Evaluation

The CDC developed the Community Health Assessment and Group Evaluation (CHANGE) tool for community members who desire to improve their community's health (CDC, 2010). CHANGE focuses on gathering and organizing data on community assets and potential areas for improvement to prioritize needs for multilevel changes in policies, systems, and the environment. [An Action Guide \(<https://openstax.org/r/cdcgovnccdp>\)](https://openstax.org/r/cdcgovnccdp) with worksheets and templates assists community members through the eight action steps within the CHANGE tool (see [Table 17.3](#)).

The CHANGE tool divides the community into five sectors: community-at-large, community institution/organization, health care, school, and work site. The community-at-large sector includes the social and built community

environments, such as safety, food access, and policies that affect health. The community institution/organization sector includes human services and facility access, such as the YMCA, senior centers, faith-based organizations, childcare, and colleges and universities. The health care sector includes emergency services, clinics, hospitals, and provider offices. The school sector includes primary and secondary learning institutions. The work site sector includes places of employment.

CHANGE Tool Action Step	Actions Taken
1: Assemble the Community Team	<ul style="list-style-type: none"> Recruit team members from diverse sectors of the community. Include key community decision makers. Ideally, have no more than 10 to 12 total members.
2: Develop Team Strategy	<ul style="list-style-type: none"> Determine how the team will collect data and complete the CHANGE tool; for example, the team may decide to divide into subgroups. Determine decision-making strategies, such as by majority vote or unanimous vote.
3: Review All Five Change Sectors	<ul style="list-style-type: none"> Develop an understanding of the big picture. Review the five sectors (by subgroups if that was decided in Action Step 2).
4: Gather Data	<ul style="list-style-type: none"> Gather data from each sector using multiple data collection methods (the CHANGE tool describes suggested methods). Gather data from multiple sites (ideally 13 or more) within each sector.
5: Review Data Gathered	<ul style="list-style-type: none"> Review data collected as a team. Rate data following the CHANGE tool parameters, which includes the team coming to a consensus rating that will be used to evaluate improvement.
6: Enter Data	<ul style="list-style-type: none"> Designate one team member to input data, including data collected, ratings, and team member comments.
7: Review Consolidated Data	<ul style="list-style-type: none"> Summarize findings. Determine areas for improvement. Develop a Community Action Plan.
8: Build the Community Action Plan	<ul style="list-style-type: none"> Create project and annual objectives. Plan for activities to meet those objectives. Evaluate the Community Action Plan annually and upon project completion.

TABLE 17.3 CHANGE Tool Action Steps

PRECEDE-PROCEED Model

The Green and Kreuter PRECEDE-PROCEED model uses a social-ecological, population-level approach to guide health promotion strategies. This model considers the impact of the social determinants of health (SDOH) and the community environment on the target population's quality of life and needs (Porter, 2016). Members of the target population participate throughout each phase of the model.

PRECEDE stands for Predisposing, Reinforcing, Enabling Constructs in Educational/Environmental Diagnoses and Evaluations. The PRECEDE process occurs before implementation of an intervention and includes the following four phases:

1. Define the outcome: Social and situational assessment of what the community wants and needs. Includes data collection and assessment.
2. Identify the issue: Select the most important issue that can be influenced by an intervention. Includes analysis and prioritization.
3. Examine factors that influence behavior, lifestyle, and responses to environment: This includes analysis of predisposing, enabling, and reinforcing factors that influence health promotion. See [Health Promotion and Disease Prevention Strategies](#) for further explanation of each factor.
4. Identify best practices for intervention and organizational issues that could have an impact: Design an action plan.

PROCEED stands for Policy, Regulatory, and Organizational Constructs in Educational and Environmental Development. The four phases of PROCEED guide the implementation of the intervention itself. PROCEED is discussed further in [Planning Health Promotion and Disease Prevention Interventions](#) as a model used for programming planning, implementation, and evaluation.

Agency for Toxic Substances and Disease Registry Action Model

The Agency for Toxic Substances and Disease Registry (ATSDR) (2023) developed an [Action Model](#) (<https://openstax.org/r/atsdr.cdc>) for community members to identify community problems and create a plan to improve the community through redevelopment (see [Figure 17.3](#)). Redevelopment consists of making changes to an area to impact health outcomes, such as repairing sidewalks and buildings, removing harmful environmental exposures, or building a playground. For example, a community with increased adolescent obesity rates decides to redevelop a park to provide areas for exercise. They add basketball and tennis courts, walking trails, and outdoor exercise equipment to the park.

Agency for Toxic Substances and Disease Registry (ATSDR) Action Model

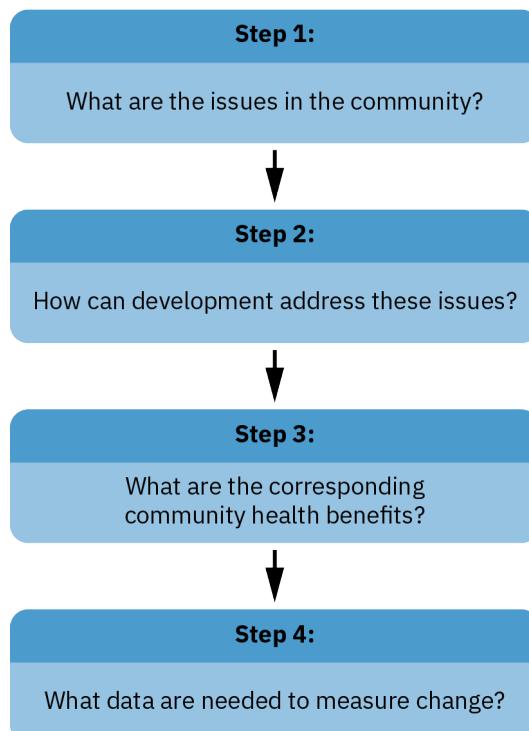

FIGURE 17.3 Community members can work through the four steps of the ATSDR Action Model to identify community problems and create a plan to improve the community through redevelopment. (credit: modification of work “The Action Model is built around four steps or questions” by Agency for Toxic Substances and Disease Registry/U.S. Department of Health and Human Services, Public Domain; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Before working through the Action Model, a team of community members who are interested in the identified issue or are impacted by the issue will play a role in redevelopment plans. [A toolkit is available \(<https://openstax.org/r/atsdr.cdc>\)](#) to walk community members through building a team and Action Model steps.

Primary and Secondary Data Sources

A CHA consists of data and information from multiple sources. Required data includes information about the community's demographics, health status, morbidity and mortality rates, socioeconomic characteristics, quality of life, community resources, behavioral factors, environment, and other social and structural determinants of health (PHAB, 2022). A comprehensive CHA needs a variety of primary and secondary data sources to gather information. In fact, PHAB requires public health departments to use primary and secondary data sources and include both quantitative and qualitative measures. **Quantitative data** are expressed by amounts in numerical terms. **Qualitative data** are expressed in word form, cannot be quantified, and describe perspectives of individuals and populations. CHA data and indicators should be valid, reliable, feasible, meaningful, and collected over time.

An assessor collects **primary data** directly from community members. PHAB considers primary data to be data for which collection is conducted, contracted, or overseen by the health department (PHAB, 2022). Collecting primary data can be time- and resource-intensive. [Table 17.4](#) describes common primary data sources.

Primary Data Source	Description
Participant observation	<ul style="list-style-type: none"> Purposeful sharing of life in a community, noting details about the people and environment Includes attendance at local events This type of data is qualitative.
Interview key informants	<ul style="list-style-type: none"> Interview people viewed as local leaders in the community. Leaders may not have a formal title or position and may include individuals from businesses, organizations, social clubs, religious congregations, civic clubs, or government. This type of data is qualitative.
Forum or town hall meeting	<ul style="list-style-type: none"> Community members congregate to discuss a particular issue or proposal that influences all community members. This may include discussions regarding health policy or infrastructure. This type of data is qualitative.
Focus group	<ul style="list-style-type: none"> Small groups of individuals (8 to 10 per group) are interviewed using mostly open-ended questions. Interactions between participants may prompt discussion or generate ideas. This is most often used to reach community members who may not be heard from in other ways. This type of data is qualitative.
Photovoice	<ul style="list-style-type: none"> Community members take photos to represent a topic or theme about the community. The photos convey visual messages about community strengths and concerns, adding depth to the CHA. This is useful when working with groups that may be marginalized or have little power. This type of data is qualitative.

TABLE 17.4 Primary Data Sources Used in Community Health Assessment

Primary Data Source	Description
Survey	<ul style="list-style-type: none"> Standardized questionnaire via mail, telephone, face-to-face, or electronic Usually developed through collaboration among multiple community partners This type of data is quantitative and qualitative depending upon survey questions.
Windshield survey	<ul style="list-style-type: none"> Simple observation while driving or walking through a community Notes common characteristics of people, housing quality, services, and geographic boundaries This type of data is qualitative.

TABLE 17.4 Primary Data Sources Used in Community Health Assessment

Secondary data are obtained through an existing report on the community originally collected by another entity or for a purpose other than CHA. Secondary data are usually readily available and may be inexpensive for the assessor. Secondary sources include census data, vital statistics, health indicators, health profiles, and spatial data. **Vital statistics** are population data about births, deaths, marriages, and divorces. **Health indicators** are numerical measures of health outcomes, such as morbidity and mortality, that have been analyzed and are used to compare rates or trends of priority community health outcomes and determinants of health. They are usually attained through secondary data sources. Health indicators provide a snapshot of community health outcomes and allow for benchmarking. A **benchmark** is a standard or point of reference against which measurements can be compared.

Sources and Methods to Access Public Health Information

A comprehensive CHA contains public health data from various sources displayed in ways to identify trends and patterns. Public health information is also used to compare local data to state and national data, which can be used for benchmarking and to trend data to evaluate progress.

Spatial Data

One method to identify trends and patterns is using **spatial data**, which identifies the geographic location of phenomena. Spatial data provide an overview of the whole community in map form and facilitate comparing one part of the community to another. This is an important tool to use when conducting a CHA because geographic location can affect access to resources and exposure to health threats. Major differences in health outcomes, especially in mortality rates, have been found even between locations within 5 to 10 miles of each other (Couillard et al., 2021; Hollar, 2016; Pedigo et al., 2011).

THE ROOTS OF HEALTH INEQUITIES

Where You Live Matters!

[Access multimedia content \(<https://openstax.org/books/population-health/pages/17-1-assessment-tools-and-application-to-practice>\)](https://openstax.org/books/population-health/pages/17-1-assessment-tools-and-application-to-practice)

A person's geographical location influences their access to healthy foods, education, jobs, safe housing and neighborhoods, facilities that promote health, and health care resources. Individuals living in neighborhoods with greater economic resources have healthier lifestyles. By identifying locations where health disparities exist, even in the same community, nurses can recognize populations at risk for negative health outcomes. Additionally, spatial data helps identify the SDOH within a location that contribute to negative health outcomes. For example, a nurse finds that higher rates of tuberculosis occur in one community area. The nurse uses spatial data to locate the geographical area of tuberculosis diagnoses and assesses potential environmental factors that influence TB's spread, such as housing and living conditions. The nurse prioritizes interventions by focusing on improving living conditions in the area.

This American Heart Association video explains why a person's zip code may be more important than their genetic code.

Watch the video, and then respond to the following questions.

1. Consider your community. What areas or locations might you compare using spatial data to clarify whether inequities exist?
2. How does location relate to social determinants of health and other environmental factors that impact health?

Geographic information systems (GIS) are software and technology that can store, visualize, analyze, and interpret spatial data (CDC, 2019a). The software creates maps electronically using primary or secondary data to determine how location impacts disease and disability. Any data that can be mapped can be used and compared by location. This helps locate areas of communities where high rates of health problems occur.

Nurses and other health care professionals can use GIS maps to identify areas within a community—such as those with higher rates of opioid overdoses, for example—to target them for intervention. Additionally, it is possible to analyze the environment in that location for potential determinants of health that lead to increased opioid use and overdose. GIS tools and examples can be found on [the CDC's website \(<https://openstax.org/r/cdc.gov/gis>\)](https://openstax.org/r/cdc.gov/gis).

USING GIS TO PREDICT OUTBREAKS

[Access multimedia content \(<https://openstax.org/books/population-health/pages/17-1-assessment-tools-and-application-to-practice>\)](https://openstax.org/books/population-health/pages/17-1-assessment-tools-and-application-to-practice)

This Queens University video describes how researchers are using GIS to create interactive maps to track information about a range of topics, such as population movement and infection rates of emerging diseases.

Watch the video, and then respond to the following questions.

1. How can maps be used in community health assessment to determine health patterns?
2. How were GIS and other assessment data used to predict the spread of COVID-19?
3. How can GIS data be used to plan for intervention within a community?

Secondary Data Sources

Public health information sources provide data on local, state, and federal health indicators. During the CHA, the team can use these secondary sources to compare local health data to other municipalities, state, and federal health data for benchmarking. All are quantitative data sources. [Table 17.5](#) describes frequently used secondary data sources and methods to access public health information.

Secondary Data Source	Description
Behavioral Risk Factor Surveillance Survey (BRFSS) <u>https://www.cdc.gov/brfss/data_tools.htm</u> (<u>https://openstax.org/r/cdcgovbrfss</u>)	<ul style="list-style-type: none"> Survey data are collected by telephone in 50 states, the District of Columbia, and three U.S. territories. Data include demographic characteristics, health conditions, and current health behaviors. Tools on the site allow users to attain state or national prevalence and trend data by health topic and compare two or more geographic areas by health indicator.
Population-Level Analysis and Community Estimates (PLACES) <u>https://www.cdc.gov/places/</u> (<u>https://openstax.org/r/cdcgovplaces</u>)	<ul style="list-style-type: none"> This site reports U.S. data at multiple local area levels (county, place, census tract, and zip code) on health risk behaviors, health outcomes, health status, and prevention practices. Tools on the site allow users to attain data by location and health measures and compare up to three geographic areas by health measures. Interactive maps are also available.
CDC Wide-Ranging Online Data for Epidemiologic Research (WONDER) <u>https://wonder.cdc.gov/</u> (<u>https://openstax.org/r/wondercdcgov</u>)	<ul style="list-style-type: none"> This site integrates public health information data sets and any statistical research data published by the CDC. Tools on the site allow users to retrieve information on mortality, common disease and disability, communicable disease, vaccinations, births, environmental and occupational health, injury prevention, and health practices. Information can be viewed at national, state, and sometimes county levels.
National Center for Health Statistics: FastStats <u>https://www.cdc.gov/nchs/fastats/default.htm</u> (<u>https://openstax.org/r/cdcgovnchsfaststats</u>)	<ul style="list-style-type: none"> This site provides national statistics on multiple health topics in the United States. Topics include several diseases and conditions, infectious disease, family life, health care and insurance, disability and risk factors, injuries, life stages and populations, and reproductive health.

TABLE 17.5 Secondary Data Sources to Enhance a Community Health Assessment

Secondary Data Source	Description
U.S. Census https://www.census.gov/ (https://openstax.org/r/census) https://data.census.gov/ (https://openstax.org/r/datacensusgov)	<ul style="list-style-type: none"> These sites report U.S. data by different geographies (national, states, counties, places, tribal areas, zip codes, and congressional districts) on topics such as population, education, housing, employment, health, business and economy, families and living arrangements, poverty, and emergency management. Data can be produced in table or map format. Detailed instructions are available to assist with data retrieval.
Healthy People 2030 https://health.gov/healthypeople (https://openstax.org/r/govhealthypeople)	<ul style="list-style-type: none"> Provides national data on 359 national objectives to improve health and well-being Can be used to compare local data to national data and objectives
County Health Rankings https://www.countyhealthrankings.org/ (https://openstax.org/r/countyhealthrankingsorg)	<ul style="list-style-type: none"> Ranks (using the County Health Rankings Model) are provided at the county level using health outcomes and health factors attained from other entities. State and national values are provided for comparison. Length of life, quality of life, health behaviors, clinical care, social and economic factors, and physical environment data are available.
State Cancer Profile https://statecancerprofiles.cancer.gov/ (https://openstax.org/r/cancerprofiles)	<ul style="list-style-type: none"> This site reports cancer data at the state level. Data include demographics, screening and risk factors, incidence, and mortality on 20+ cancer sites. National data are provided for comparison. Data are provided in statistic, chart, and map formats.
State Health Access Data Assistance Center https://www.shadac.org/ (https://openstax.org/r/shadac)	<ul style="list-style-type: none"> Provides state-level data on health insurance, cost of care, health care access and utilization, health behaviors and outcomes, and affordability of care Includes national data for comparison
State Health Assessment See state public health department websites for state health assessments.	<ul style="list-style-type: none"> Provides CHA data gathered at the state level Can be used to compare local data to state data or to compare state to state

TABLE 17.5 Secondary Data Sources to Enhance a Community Health Assessment

Secondary Data Source	Description
Tribal Health Assessment See tribal health department websites for tribal health assessments.	<ul style="list-style-type: none"> Provides CHA data gathered at the tribal level Can be used to compare local tribal data to previous local data, other tribal health data, or state or national data
Local Health Assessment See local health department websites for local community health assessments.	<ul style="list-style-type: none"> Provides CHA data gathered at the local level Can be used to compare local data to previous local data, similar counties/communities, state, or national data

TABLE 17.5 Secondary Data Sources to Enhance a Community Health Assessment

HEALTHY PEOPLE 2030

Reduce Drug Overdose Deaths

Drug overdose deaths are one common health indicator measured within a CHA and are considered a national emergency. As such, a leading health indicator of Healthy People 2030 within Drug and Alcohol Use objectives is [reducing drug overdose deaths \(<https://openstax.org/r/peopleobjectives>\)](https://openstax.org/r/peopleobjectives). The target goal for this health indicator is 20.7 drug overdose deaths per 100,000 people, which was the baseline measure in 2018. In 2020, 28.3 drug overdose deaths per 100,000 individuals occurred; in 2021, 32.4 drug overdose deaths per 100,000 individuals occurred.

At this time, the 2020 and 2021 data signify that drug overdose deaths have increased in the United States. This aligns with the public health emergency declaration for the opioid crisis.

Conducting a Community Health Needs Assessment

The first steps of conducting a CHA, no matter the framework, model, or tool chosen as a guide, are planning, engaging the community, and recruiting the assistance of key community partners. After creating the team and determining team roles, the next step is defining the community and the data collection process.

A community may be defined by geography or place of residence, shared characteristics or demographics, or common interests. PHAB (2022) defines a community as a group of people with common characteristics; this can be defined by location, race, ethnicity, age, occupation, interest in particular problems or outcomes, or other common bonds. The definition of the community may change depending upon the context. For a CHA, the community should be defined by people, place or environment, and community systems. [Table 17.6](#) clarifies data that fall under each category.

Category	Data Included
People: Who are the people within the community?	<ul style="list-style-type: none"> Demographics and vital statistics (size and density of population, age, gender, race, ethnicity, income, education level, household makeup) Health indicators and health behaviors Morbidity and mortality patterns (leading causes of death and disability) Values and beliefs
Place: Where is the community? What is the physical environment?	<ul style="list-style-type: none"> Geographical boundaries Distance and relation to other communities Community size Historical information Physical environment (water quality, indoor and outdoor air quality, climate, pollution)
Community systems: What services and resources are available?	<ul style="list-style-type: none"> Safety (crime, police, fire, EMS, sanitation, laws) Transportation Politics and government (government buy-in and focus on health) Educational opportunities (all levels) Recreation (safe indoor and outdoor areas) Economics (existing jobs, unemployment, types of industry) Businesses and services Communication (phone, radio, internet, TV, media) Religious or spiritual organizations Social clubs (civic clubs, neighborhood associations) Availability of healthy foods Built environment (housing, sidewalks, roads) Emergency disaster planning Aesthetics (art, music, culture) Health and social services (health care providers, hospitals, hospice, emergency care, mental health care, specialty services)

TABLE 17.6 People, Place, and Community Systems Used to Define Community Within a CHA

Data gathering is required to assist with defining the community. A rich CHA and definition of the community contain both quantitative and qualitative data, and PHAB requires a CHA to show evidence of both (PHAB, 2022). To provide a comprehensive picture of the community, the CHA should include several primary and secondary data collection methods to define the community. Refer to [Table 17.4](#) for potential primary data sources and [Table 17.5](#) for potential secondary data sources. Primary data sources may include qualitative data, quantitative data, or both. Secondary data sources are quantitative in nature.

The community health nurse focuses on data regarding areas of need. This includes mortality, morbidity, and other health outcome data, such as SDOH. A comprehensive review of access to education, healthy nutrition, transportation, healthy spaces, resources for exercise, health care services, economic opportunities, a healthy environment, and employment provides perspective on potential causes of negative health outcomes and areas for improvement.

The community health nurse should not focus only on data regarding areas of need, but on areas of strength and potential resources as well. The values and beliefs of the community, available resources, and current and potential funding are considered. Community values and beliefs are important to ensure community buy-in when programs are implemented to target an identified area of concern. Although statistical health data may indicate poor outcomes in one area, other health-related areas may be of greater concern and importance to community members. Evaluation of the adequacy of community systems should also occur. One method to assess the extent to

which community agencies successfully provide support is the seven As (Truglio-Londrigan & Gallagher, 2003):

- Awareness: Community members are aware that a service is needed and know where to attain that service.
- Access: Community members can contact the agency, can navigate the agency's technology, and have no limitations in getting to the service.
- Availability: Service is offered at a time, location, and place that is convenient for community members.
- Affordability: Community members are able to pay for the service.
- Acceptability: Community members perceive that the service is meeting their needs.
- Appropriateness: Community members believe the service is suitable.
- Adequacy: Service is provided in sufficient quantity or degree.

Assigned individuals or groups within the CHA team carry out the work of data collection. Most often, the local public health department or health care system provides team leadership. Some CHA teams may decide to hire outside professionals to conduct the work of data collection and subsequent work writing in collaboration with the CHA team.

Most CHAs include surveys mailed to randomly selected community members. The team creates surveys in collaboration with various community partners and organizations that provide care to community members. Most often, these individuals and organizations have information that they need to determine if the care and programs they provide are still needed and effective. For example, a representative from the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) may be a part of the CHA team and ask that data regarding breastfeeding is collected. This ensures that the data collected is not only useful to the public health department, but to community partners as well.

Key interviews or focus groups add important qualitative information regarding the values and beliefs of the community. Examples of questions that may be asked to determine the values, beliefs, and concerns of community members include the following:

- What do you consider to be the major health concerns of the community?
- What do you consider to be the least important health issues of the community?
- What are some of the current efforts to address health concerns of the community?
- What do you consider to be strengths of the community?
- What do you consider to be challenges of the community?
- What do you consider to be needs of community members that are not being addressed?
- In your opinion, why are those needs not being addressed?

Youth data may be difficult to collect. School-age children complete multiple required assessments per year, which takes away from instruction. Additionally, parents must provide permission for assessment, which is not always granted. Often youth data are derived from either data collected by other agencies or organizations or by surveys completed by school-age youth enrolled in local schools. For example, [the Ohio Healthy Youth Environment Survey \(OHEYES!\) \(https://openstax.org/r/oheyes\)](https://openstax.org/r/oheyes) is a free survey schools can use to collect data from students in grades 7 to 12 (Ohio Department of Health, 2023). It includes questions about health, safety, and behavior health factors.

Data collection ends when all planned assessment tasks are conducted and the data represent a comprehensive view of the community. The data are collated into a final written report and presented by topic. Most often, the CHA report contains topic areas such as health care access, adult health behaviors, chronic disease, social conditions, youth health, and demographics. The data are presented in written format, tables, graphs, and images to highlight areas of strength and concern. Examples of current CHA reports can be found on most public health department or health care system websites.

UNFOLDING CASE STUDY

Part A: Conducting a CHA

Read the scenario, and then answer the questions that follow.

After contacting community members, Tia joined an assessment team with the goal of implementing interventions

to combat the opioid crisis. The team chose the PRECEDE-PROCEED model to guide its assessment and planning for intervention. During the first phase, social assessment, data regarding community needs and desires are collected. The team found that community members are concerned about the current opioid crisis and would like to reduce substance misuse and overdose death rates. During the second phase, epidemiological assessment, the team gathers data from primary and secondary sources and considers behavioral and environmental factors contributing to the opioid crisis. During the third phase, educational and ecological diagnosis, the team identifies predisposing, enabling, and reinforcing factors of the opioid crisis.

1. The team plans to gather qualitative information from key community partners regarding the opioid crisis during the first step. Which of the following data collection strategies would be appropriate?
 - a. Collecting survey responses from community members
 - b. Using GIS to map incidences of opioid overdose deaths
 - c. Gathering local overdose statistics to compare to national data
 - d. Conducting a focus group with local emergency responders
2. Which of the following would be categorized as an enabling factor for addressing opioid misuse?
 - a. A drug rehabilitation center is located within the community.
 - b. Local media promotes community naloxone training.
 - c. High school students gain knowledge of the consequences of opioid misuse.
 - d. A cycle of drug misuse is linked to specific families in the community.

17.2 Assessment of Individual and Community Needs for Health Education

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 17.2.1 Define health literacy.
- 17.2.2 Assess the health literacy of a population to guide health promotion and disease prevention activities.
- 17.2.3 Examine one or more health literacy assessment tools.
- 17.2.4 Examine how people learn and the factors that influence learning and knowledge acquisition.

Nurses working in the community regularly use health education to help clients promote, maintain, and restore health. Effective educators assess the individual or community for learning needs and health literacy, understand how people learn, utilize one or more learning theory models, promote factors that influence learning, and attempt to decrease factors that hinder learning and knowledge acquisition. Assessment of individual and community needs for health education may occur during the CHA process, but a more in-depth assessment is often needed.

Identifying community health education needs, including personal and organizational health literacy, is a necessary part of assessment. Limited health literacy is associated with greater emergency care use, increased hospitalizations, reduced preventative screening, lower vaccination rates, poorer ability to interpret health-related messages and labels, and poorer ability to take medications appropriately (Berkman et al., 2011).

Health Literacy

Only 12 percent of U.S. adults have the health literacy skills to manage the complex U.S. health care system (Agency for Healthcare Research and Quality, 2020). This leads to mismanagement of client conditions, increased risk for disease and disability, reduced health promotion and disease prevention behaviors, and negative client outcomes. One overarching goal of Healthy People 2030 is to “eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all” (Office of Disease Prevention and Health Promotion, 2021, para 1). Healthy People 2023 defines two types of health literacy, personal and organizational. **Personal health literacy** is the degree to which individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others. **Organizational health literacy** is the degree to which organizations equitably enable individuals to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.

These definitions emphasize an individual’s ability to understand and use health information to make well-informed decisions. Health literacy also involves acting on the understanding of health information in all situations, such as

making decisions regarding voting on health-related policy, choosing a health care provider, or even choosing where to live (Santana et al., 2021). The organizational definition acknowledges that organizations are responsible for addressing health literacy and ensuring equity of health literacy.

CONVERSATIONS ABOUT CULTURE

Five Things to Know About Health Literacy

[Access multimedia content \(<https://openstax.org/books/population-health/pages/17-2-assessment-of-individual-and-community-needs-for-health-education>\)](https://openstax.org/books/population-health/pages/17-2-assessment-of-individual-and-community-needs-for-health-education)

Health care is a culture with its own language and systems that are unfamiliar to many clients. This includes clients who speak English, those with limited English proficiency, and those who have difficulty reading and using numbers. Health information and health care services may be challenging to find, understand, and use, yet health literacy is key in understanding and applying health information. This video describes populations at greatest risk for health literacy challenges and strategies nurses, other health care professionals, and organizations can use to improve health literacy.

Watch the video, and then respond to the following questions.

1. What populations are at greatest risk for literacy challenges?
2. What can organizations and health professionals do to improve health literacy?
3. What are strategies nurses may use to check that clients understand information?

Population Health Literacy Assessment to Guide Health Promotion and Disease Prevention Activities

Including health literacy assessment as a component of the CHA helps the nurse understand the health education needs of individuals and communities. The health literacy level of individuals, **aggregates**, and community guides health promotion and disease prevention activities. An aggregate is a specific subgroup of a community or population. Individual, aggregate, and community health literacy skill levels impact health-related decisions and behaviors. Three levels of health literacy include functional, interactive, and critical (Table 17.7) (Nutbeam & Muscat, 2020). Understanding health literacy levels guides the nurse in choosing appropriate health promotion and disease prevention activities that align with the client's current health literacy level and enhance health literacy by utilizing activities associated with the next level. Health literacy assessment should be ongoing to evaluate the effectiveness of health promotion and disease promotion activities.

Health Literacy Level	Skills Present	Activities to Enhance Health Literacy	Examples of Activities
Functional health literacy	<ul style="list-style-type: none"> • Basic skills • Able to obtain relevant information and apply it to prescribed activities 	<ul style="list-style-type: none"> • Direct education and communication with defined goals and in specific contexts • Make information available 	<ul style="list-style-type: none"> • Teach clients how to read a new prescription label • Provide a link to a website that contains evidence-based information about a new diagnosis
Interactive health literacy	<ul style="list-style-type: none"> • More advanced skills • Able to extract health information and derive meaning from different forms of communication • Can apply information in varying circumstances • Interacts with others to assist in decision-making • Able to discriminate between different sources of information • Able to use interactive websites and mobile apps 	<ul style="list-style-type: none"> • Education and communication to develop personal skills • Empowerment to act independently • Make information available 	<ul style="list-style-type: none"> • Suggest a mobile app to monitor blood glucose trends and dietary patterns • Discuss the credibility of sources the client has used to gather information regarding treatments for cancer diagnosis

TABLE 17.7 Health Literacy Levels Guide Health Promotion and Disease Prevention Activities

Health Literacy Level	Skills Present	Activities to Enhance Health Literacy	Examples of Activities
Critical health literacy	<ul style="list-style-type: none"> • Most advanced skills • Able to critically assess information from an array of sources relating to a greater range of the determinants of health • Integrates personal health risks as well as social, economic, and environmental determinants of health • Uses information for greater control over life events and situations 	<ul style="list-style-type: none"> • Education to develop transferable skills that allow interactive and critical thinking • Communication that provides support • Make information available 	<ul style="list-style-type: none"> • Provide education regarding the SDOH • Provide resources on how to decrease environmental risks in the home (lead, radon, etc.)

TABLE 17.7 Health Literacy Levels Guide Health Promotion and Disease Prevention Activities

Health Literacy Assessment Tools

Including health literacy assessment as a component of the CHA helps the nurse understand the health education needs of individuals and communities. CHA teams can include health literacy assessment questions in CHA surveys, interviews with key community partners, and focus groups. Individual assessment of health literacy of targeted, high-risk populations can occur using a personal health literacy assessment tool. Organization health literacy assessment tools are available to assess community health systems. Including the results of this information in the final CHA report will highlight a community's educational health literacy needs and changes needed within community health systems to enhance the health literacy of consumers. Health literacy assessment tools are available to assess health literacy skills at the personal and organizational levels.

Personal Health Literacy Assessment Tools

Personal health literacy assessment tools measure an individual's ability to find, understand, and use health-related information and services and help the nurse determine a client's health literacy level. The client's health literacy level will guide interventions, including educational tools the nurse uses to provide health information and to improve health literacy.

Multiple tools are available that measure different aspects of health literacy. For example, [The Health Literacy Tool Shed \(<https://openstax.org/r/healthliteracy>\)](https://openstax.org/r/healthliteracy) (Boston University, 2023) is an online database that contains information about health literacy assessment tools. Over 200 free and paid tools are available to measure terminology comprehension, application, information seeking and eHealth, and media comprehension of medicine, dentistry, genetic, and general health literacy. Tools are available for adults and youth in a variety of languages and for specific diagnoses such as cancer, diabetes, high blood pressure, HIV, infectious disease, intellectual disability, kidney transplant, mental health, oral health, and vascular surgery.

Organizational Health Literacy Assessment Tools

Organizational health literacy assessment guides health promotion and disease prevention activities at the organizational and systems level. Organizational health literacy assessment tools identify areas of strength and areas for improvement. These findings guide the organization in health literacy improvement efforts at the systems

level. Assessment findings should be reported to the organization's committee that deals with health literacy and key organization administrators. For example, [the Health Literacy Environment of Hospitals and Health Centers \(HLE2\) tool](https://openstax.org/r/hsp harvardedu) (<https://openstax.org/r/hsp harvardedu>) measures organizational policies, institutional practices (resources, staff orientation and development, and expectations), navigation within the organization (signage and staff assistance), culture and language (respect for diversity, language serves, and staff training), and communication (print materials, forms, websites, and patient portals). The HLE2 suggests focusing on percentage scores for each section of the assessment tool as a way to identify strengths and weaknesses, select priority areas, and generate ideas for action (Rudd et al., 2019).

The Agency for Healthcare Research and Quality (2020) created [the AHRQ Health Literacy Universal Precautions Toolkit](https://openstax.org/r/ahrq) (<https://openstax.org/r/ahrq>) to help organizations take steps to simplify communication and confirm client comprehension, improve navigation of the environment and health care system, and support efforts to improve health. The CDC (2019b) provides [additional resources](https://openstax.org/r/cdc) (<https://openstax.org/r/cdc>) to assess organizational health literacy and tools to train staff, develop client materials, meet the needs of consumers with a range of health literacy skills, improve access to health information and services, and communicate clearly during crises.

Learning Process for Knowledge Acquisition

Disease prevention and health promotion begin with education of the individual and communities. **Education** is the establishment and arrangement of events to facilitate learning and skill development. **Learning** is the process of gaining knowledge and skills that lead to behavioral changes. Effective evidence-based community education programs are needed to increase health literacy, decrease health disparities, promote disease prevention, and promote health. Learning theories, health promotion models, and educational principles explain behavior and assist nurses in guiding community health strategies and choosing which intervention will be more likely to increase learning. Nurses should consider the identified health problem, population, and context of the planned program when choosing a learning theory or model. Often disease prevention and health promotion programs utilize one or more theories or models.

Selected Learning Theories

To provide effective health education to individuals and communities, nurses must understand the three domains of learning—cognitive, affective, and psychomotor. The cognitive domain is related to knowledge and includes thinking, memory, recognition, understanding, and application, moving from simple to complex. An example is the learner stating three signs of diabetes. The affective domain is related to perceptions and feelings, including changes in attitudes and development values. An example is a client with diabetes stating they feel as if they can manage their symptoms. The psychomotor domain is the performance of skills that require neuromuscular coordination. Learning in this domain depends on ability, a sensory image of how to carry out the skill, and practice. An example is self-administration of insulin.

Learning theories frequently used in community health education programs include behaviorism, social cognitive learning theory, constructivism, and adult learning theory. [Planning Community Health Education](#) discusses learning theories in more detail.

Factors That Influence Learning and Knowledge Acquisition

Nurses must consider factors that influence learning and knowledge acquisition when planning disease prevention and health promotion community educational programs. Age, culture, language, reading and comprehension skills, technology, and learner characteristics and experiences influence learning and knowledge acquisition, as do educator characteristics, experiences, and preparation. Learner characteristics include health literacy, self-efficacy, and motivation. Educator characteristics and preparation are public speaking, teaching or classroom/group management, choice of learning theory and teaching strategy, and planning.

Educator preparation and planning significantly impact the factors that influence learning and knowledge acquisition. Following the steps in the development of community education programs and choosing effective, evidence-based theories and strategies decrease both learner-related and educator-related barriers to learning. The educational method chosen should meet the learning needs of the population and have the greatest impact.

STEPS IN DEVELOPING A COMMUNITY-BASED EDUCATION PROGRAM

1. Identify population learning need.
2. Establish goals and objectives.
3. Select appropriate educational methods.
 - a. Select learning theories to use.
 - b. Consider educational principles that are most appropriate.
 - c. Examine educational issues/barriers.
4. Design and implement the educational program.
5. Evaluate the educational process and effects of the program.

Identifying a population's learning needs occurs with community health assessment; these needs are then prioritized in the analysis phase. Assessment also identifies a population's age, culture and language, educational level, and potential barriers to learning. Individual learner assessment can be used to clarify those learning needs and identify learner characteristics, including learning style, health literacy, and readiness to learn.

Educational methods should align with the age and developmental level of the target population. Pedagogy, where the teacher holds full responsibility for the teaching-learning process, is appropriate for children. Additionally, younger children require concrete examples, interactive activities, and repetition for knowledge acquisition. In contrast, adults learn best using andragogy, where learners share the responsibility of developing learning goals. This corresponds with the principles of adult learning theory.

When choosing educational methods, nurses should consider the target population's cultural beliefs, language barriers, educational level, health literacy, and motivation. Content and materials should align with cultural beliefs. Multilingual materials (presentation and written) may be needed. Additionally, because more than half the U.S. population ages 16 to 74 reads below a sixth-grade reading level (Schmidt, 2022), written educational materials should use plain language and be no higher than a fourth- to sixth-grade reading level (CDC, 2022). Content and materials should also align with health literacy levels. Refer to [Table 17.7](#) for examples of teaching strategies for functional, interactive, or critical health literacy levels. Finally, aligning a learner's motivation with the chosen teaching strategy facilitates learning.

Because individuals process information differently, nurses should consider the target population's learning styles when choosing educational methods. Visual learners think in pictures or images and learn best through seeing and visualization. Appropriate educational methods for visual learners include taking notes and viewing videos, presentations, and pictures or images. Auditory learners process information and learn best through listening; appropriate educational methods are verbal lecture, discussion, music, podcasts, and reading aloud. Tactile-kinesthetic learners process information and learn best through doing and exploration. Appropriate educational methods are learning by trial and error, hands-on or interactive activities, and return demonstration.

Theory should be a foundation for community program planning and development and is consistent with the current emphasis on using evidence-based interventions in public health (Lhachimi et al., 2016). The chosen theory's assumptions about a behavior, health problem, target population, or environment should be a good fit, logical, consistent with observations, similar to those used in previous successful programs, and supported by research (National Cancer Institute, 2005).

Finally, the educator considers the learning environment. To stimulate learning and reduce barriers, nurses should create a comfortable, distraction-free environment that encourages interaction. The educator needs experience managing a learning environment and the skills to minimize distractions, present content to enhance learner comprehension, evaluate teaching methods throughout the learning process, modify plans as needed to meet learner needs, and manage technology.

17.3 Analyzing Population Health Data and Identifying Patterns

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 17.3.1 Identify health patterns across populations by comparing data at the local, regional, tribal, and national levels to benchmarks.
- 17.3.2 Analyze behavioral, environmental, and other factors influencing health.
- 17.3.3 Synthesize assessment findings to prioritize education/health promotion/disease prevention needs, resources, and capacity.

The second stage of the nursing process for individual clients, diagnosis, is similar to community diagnosis.

Members of the CHA team organize, explore, and synthesize data gathered in the assessment phase. They compare CHA data to previous health assessments and to data from adjacent counties and communities as well as state and national data to determine if benchmarks have been met or if efforts have fallen short. The CHA team reviews the data for specific community health problems and other factors influencing health, areas where the community is doing well, and identified resources. The steps of data analysis of community health data are as follows:

1. Gather collected data into one place.
2. Assess collected data for completeness.
3. Identify and generate missing data.
4. Synthesize data and identify themes.
5. Identify community needs and problems.
6. Identify community strengths and resources.

Steps 1 to 3 involve organization and analysis of data to identify health patterns and factors that influence health. The team compares local data to benchmarks at local, regional, tribal, and national levels. Steps 4 to 6 synthesize assessment findings to prioritize education, health promotion, and disease prevention needs, resources, and capacity.

Analyze Data to Identify Health Patterns and Factors That Influence Health

First, the CHA team completes a statistical analysis of survey data and other quantitative information. Most often, the data are presented in frequencies, percentages, and/or central tendencies. Primary and secondary data are organized by topic or health pattern to assess completeness and determine if data are missing. If data appear to be missing, the team collects additional information. For example, if input from an at-risk population is missing, the team may hold a focus group to gather the missing data.

Morbidity and mortality data collected in the current assessment are presented along with previous assessment, state, and U.S. data, usually in table format. The team may also include other local municipality or county data. If data are available, the specific population at risk is noted. Specific populations at risk may be designated according to age, income level, gender, race/ethnicity, and/or geographical location. These data are used to benchmark state and federal data and evidence-based health standards. CHA teams may use the State Health Assessment/State Health Improvement Plan (refer to [Table 17.5](#)) to benchmark against the state. Healthy People 2030 also contains evidence-based federal standards that can be used for benchmarking.

Next, the team reports on factors influencing health in written or table format. Factors include health care access, health behaviors, and environmental and social conditions such as economic stability, education, neighborhood and built environment, and social and community context. The report may also include data from other localities, the state, and the United States for benchmarking purposes. Including [the County Health Rankings Model](#) (<https://openstax.org/r/county>) described in [Social Determinants Affecting Health Outcomes](#) ensures SDOH and other factors that influence health outcomes are part of the CHA and analysis.

By this point, the CHA team should have a comprehensive picture of the occurrence and distribution of health patterns and health factors and be able to answer the following questions:

- What is the health concern (or health factor), and to what extent is it occurring?
- Who is impacted by the health concern (or health factor)? Is one aggregate affected more than others?
- Where is the health concern (or health factor) most prevalent?

- When, if applicable, is the health concern (or health factor) occurring?

Synthesize Assessment Findings to Prioritize Needs

Synthesis aims to critically analyze each health concern to identify why and how the problem is occurring. This step moves past identifying and organizing the data and links factors influencing health to each health concern. The MAPP framework discussed previously offers tools to assist synthesis (NACCHO, 2023). The MAPP strategic issues identification worksheet guides the time to identify an issue and provides a rationale on why it is an issue and the consequences of not addressing it. The strategic issues relationship diagram illustrates how information from different assessments relates to the identified issue.

Common health needs and themes emerge, and the team creates a problem list of no more than 12 issues based on a synthesis of primary and secondary community assessment data (NACCHO, 2023). This can be managed by merging similar topics into one theme. Each problem should include the aggregate most impacted, community needs or gaps, available community resources, and capacity for change. The problem list is prioritized as part of the next phase of the community nursing process.

17.4 Formulating a Nursing Community Diagnosis and Plan of Care

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 17.4.1 Utilize various approaches and assessment findings to identify and prioritize individual, family, community, system, and population health concerns.
- 17.4.2 Appraise the level of nursing intervention to make the most impact.
- 17.4.3 Integrate individual, family, community, system, and population experiences and perspectives in designing plans of care.
- 17.4.4 Develop a nursing community diagnosis and plan of care tailored to community culture.

Formulating a nursing community diagnosis and plan of care is similar to individual nursing community diagnosis and care planning. First, the CHA team identifies and prioritizes community health concerns. Next, the team develops community nursing diagnoses. Finally, the team tailors a community health improvement plan to community culture.

Prioritize Health Concerns

The CHA team uses the identified problem list created during analysis to prioritize community problems based on:

- Extent of the problem (percent of the population affected by the problem and perception of health needs)
- Relevance of the problem (degree of risk and economic loss)
- Estimated effect of the intervention (impact, improvement of health outcomes, and potential adverse effects)

Health priorities should be those for which intervention would make the most impact on the community as a whole or for a specific at-risk population. Health priorities are those that have the

- highest community perception of need,
- largest reach,
- highest degree of risk if unaddressed,
- greatest economic impact,
- greatest opportunity for improvement in health outcomes,
- opportunity to promote health equity and reduce health disparities, and
- least adverse effect on the population.

The team should base priorities on community strengths and available resources to increase the possibility of successful implementation of programs targeting those priorities. Resources include current and potential partnerships and collaborations, human resources or capacity, and funding. Health concerns may also be prioritized because they align with state and federal priorities, allowing for benchmarking and comparison to state and local data. Additionally, monies are usually available to fund programs that align with state or federal priorities.

The method the CHA uses to prioritize health concerns is determined by the CHA model, framework, or tool it chose

at the beginning of the process. For example, a CHA team using the MAPP framework will first rank identified problems individually and then use a consensus to choose priorities or strategic issues. MAPP offers several tools to guide this process (NACCHO, 2023). In contrast, a CHA team using the Community Health Assessment toolkit would first identify specific criteria for prioritization and then choose an approach, such as group vote with majority deciding, averaging individual rankings, or using a matrix to weigh and rank criteria according to several factors (baseline data, feasibility, availability of resources, etc.) (AHA, 2017).

PHAB (2022) requires at least two health priorities, but most community care plans or community health improvement plans include at least three priority topics. Choosing health priorities also includes picking at least one health outcome indicator to measure health problem changes and identify the priority population of focus. For example, a team may choose mental health and addiction as a health priority. The priority outcome of this focus should then align with data collected during the CHA. Examples of mental health and addiction topic priority outcomes are “decrease the percentage of the community with depression,” “decrease suicide deaths,” and “decrease drug overdose deaths.”

Develop the Community Nursing Diagnosis

The community nursing diagnosis includes only one identified priority and the aggregate (population) affected, and it provides a rationale. A community nursing diagnosis should be written for each selected priority and include these three parts:

1. *Risk of:* Identifies a specific problem or health risk faced by the community
2. *Among:* Identifies the specific community aggregate with whom the nurse will be working in relation to the identified problem or risk
3. *Related to:* Describes characteristics of the community

The community problem must be observable and measurable at the aggregate level. It considers which aggregate the risk affects most and which intervention will have the biggest impact. The community’s characteristics may contribute to the identified problem and/or be strengths of the community that can be built upon.

Examples of appropriately written community nursing diagnoses are as follows:

- Risk of drug overdose among Hardin County adults related to increased opioid usage, presence of fentanyl, lack of available naloxone, ineffective drug misuse prevention programs, and decreased access to drug rehabilitation programs
- Risk of infant and child malnutrition among families in Richmond County related to lack of regular developmental screenings, knowledge deficit about infant-related and child-related nutrition, knowledge deficit about available community resources, and lack of access to healthy foods
- Risk for cardiovascular disease among Bailey County adults related to sedentary lifestyles, lack of walking trails, lack of safe sidewalks, and lack of affordable exercise facilities

UNFOLDING CASE STUDY

Part B: Conducting a CHA

Read the scenario, and then answer the questions that follow based on all the case information provided in the chapter thus far. This case study is a follow-up to Case Study Part A.

After selecting the PRECEDE-PROCEED model, Tia’s CHA team completed phases 1–3. During the assessment, the team collected the following data:

- GIS data shows one neighborhood with a disproportionate number of drug overdoses. This area also has high poverty and unemployment rates and is located by an entrance/exit on the interstate.
- EMS calls for overdoses have tripled since the last CHA.
- Drug overdose deaths are higher than the national benchmark (Healthy People 2030).
- Provider opioid prescriptions have decreased in the area.
- Reported opioid use (attained by any method—legal or illegal) has increased. Heroin usage has increased by

10 percent.

- Availability of heroin mixed with fentanyl has increased over the past 6 months.
- Infection rates related to needle use have increased at the local hospital.
- Local schools continue to educate on drug abstinence using the Drug Abuse Resistance Education (DARE) program.
- Naloxone training is available from the public health department, but utilization goals have not been reached.
- Local EMS staff are volunteers, and the station is not regularly staffed.
- A drug rehabilitation center is located within the community but frequently has a waiting list for outpatient appointments and inpatient admission.

Although the PRECEDE-PROCEED model does not require a community nursing diagnosis, the team decided to create one in order to clearly identify the aggregate and characteristics of the community.

The team has started planning for program implementation and wants to begin by promoting and enhancing available community resources, such as education within the schools, community naloxone training, education for providers related to opioid prescriptions, and drug rehabilitation. According to the PRECEDE-PROCEED model, phase 4, administrative and policy diagnosis, the team focuses on administrative and organizational concerns that should be addressed prior to program implementation.

3. Which community nursing diagnosis is written appropriately, reflects the data gathered during assessment, and aligns with community perceptions and needs?
 - a. Risk for overdose among opioid/heroin users related to increased availability of heroin mixed with fentanyl, inconsistent EMS staffing, lack of availability/access to drug rehabilitation resources, increased opioid usage in the community, lack of knowledge of consequences of opioid misuse, and lack of utilization of community naloxone training
 - b. Opioid misuse among community members living next to the highway who are unemployed and lack financial resources
 - c. Risk for infection related to heroin injection, lack of knowledge of aseptic technique for injection, and availability of clean needles
 - d. Increased opioid use in the county related to availability of heroin
4. Using the data collected during assessment and tentative plans for the program, what administrative and organizational concerns must the team address before program implementation?
 - a. Reduced rates of opioid prescriptions by providers in the area
 - b. Availability of appointments at the local drug rehabilitation center
 - c. Response times of local EMS to overdose calls
 - d. Increased availability of heroin in the community

Develop the Community Health Improvement Plan

The CHA team uses the identified priorities and community nursing diagnoses to develop the **community health improvement plan** (CHIP), the care plan for the entire community. PHAB (2022) defines the CHIP as a long-term systematic plan to address issues identified in the CHA that describes how the health department and community will work together to improve population health. Frequently, the public health department holds a leadership role, collaborating with various diverse community organizations to create the CHIP. The members of the CHA team are also usually involved in the CHIP process. As stated previously, the team members are individuals who either work or live within the community, ensuring the CHIP represents the community culture and values. The plan outlines goals and strategies community organizations, coalitions, and members will use to address priority health problems.

The team considers potential interventions for each identified priority. First, the team discusses existing community programs that may meet the community health need. The team performs a **gap analysis** to determine where the community should expand its efforts to meet community health needs. A gap analysis identifies and addresses the disparity between what is desired and real-world conditions (Davis-Ajami et al., 2014). For example, access to primary health care is a desired community health outcome for all. In reality, all people do not have access to a primary health care provider. A gap analysis identifies the disparity and potential solutions to reduce it. The team brainstorms strategies to enhance current programming and identify potential new interventions to fill the gaps

noted to promote health and prevent disease. The team searches for new interventions that meet community needs and are innovative, evidence-based, most impactful, and sustainable. The team should also consider new partnerships to assist with planning or implementation. Finally, the team may complete a SWOT analysis to identify strengths, weaknesses, opportunities, and threats that may influence health outcomes or may promote or hinder possible interventions. The Minnesota Department of Health provides [more information on completing a SWOT analysis \(<https://openstax.org/r/state>\)](https://openstax.org/r/state). Overall, the team should select the best intervention after considering the various factors discussed.

The CHIP is designed to immediately follow the CHA and is updated with the CHA. So if the CHA process occurs every 3 years, the CHIP should be written as a three-year plan. CHIP interventions must align with chosen priorities and include measures for evaluation related to the rationale identified within the corresponding community nursing diagnosis. Current community resources and strengths are considered and integrated into interventions. The CHIP development also considers currently available and potential resources (such as grants) and partnerships. Community interventions are chosen when they are impactful, have the largest reach, are feasible, are innovative, are evidence-based, and can be completed within the CHIP time frame.

CHIP development continues by detailing goals and objectives, action steps, timetables, priority target populations, indicators to measure strategy impact, and accountability. Objectives should be SMART (specific, measurable, achievable, relevant, and time-bound). Action steps are specific and are listed by year of implementation. The time to complete each action step, target population, health indicator to measure the strategy, and responsible individual or organization is determined. Other details of the interventions are further detailed by the responsible individual or organization during program planning. See [Planning Health Promotion and Disease Prevention Interventions](#) for more information on writing SMART objectives.

The CHA and CHIP provide community organizations and health care systems with a common plan for addressing community health issues. The community is a partner in planning for health promotion and disease prevention efforts with community perspectives and community engagement at the center of the process. A comprehensive CHA provides evidence for community health priorities and social determinants of health impacting community health outcomes. The CHIP utilizes established community resources to combat identified priorities and reduce health disparities caused by determinants of health.

Chapter Summary

17.1 Assessment Tools and Application to Practice

CHA is the first step of the nursing process for populations and communities. It uses a systematic, collaborative approach to gather primary and secondary data to comprehensively describe the community. It uses frameworks, models, and tools to guide community assessment. The process defines people, place, and community systems using a variety of primary and secondary data sources that include quantitative and qualitative data. Throughout the assessment process, collaboration with the community and multiple partners ensures that community needs for health promotion and disease prevention are met.

17.2 Assessment of Individual and Community Needs for Health Education

Analysis of community health assessment data is the second step of the community nursing process using a team approach to organize and synthesize collected data. The team compares local data to previous assessments and other local community, state, and national data. The team organizes the data to describe the problem, whom it effects, where it occurs, and when it occurs. The team creates a list of no more than 12 community health problems to consider for intervention. Further analysis of the identified health problems includes answering why and how the problem is occurring. The team gathers information to help answer those questions and prioritize the problems. Information includes community strengths and resources, at-risk populations, health disparities and inequities, and the consequences of not intervening.

Key Terms

aggregate a specific subgroup of a community or population

benchmark a point of reference or standard against which measurements can be compared

coalition a group of people and organizations who work to address community needs and solve community problems

community engagement the process of working collaboratively with and through groups of people to identify the health needs of community residents and strategies to address those needs

community health assessment (CHA) provides a comprehensive picture of a community's current health status, factors that contribute to higher health risks or poorer health outcomes, and

17.3 Analyzing Population Health Data and Identifying Patterns

Most community health programs use education as a strategy for health promotion and disease prevention. Health literacy and other factors that influence learning and knowledge acquisition should be assessed at the community level within the CHA and at the individual and aggregate levels when planning for interventions. Tools are available to assist in assessment of personal and organizational health literacy. Learning theories and health promotion models guide assessment and planning for education and learning. Factors that influence or hinder learning acquisition should also be considered during assessment of health education needs and when planning for education.

17.4 Formulating a Nursing Community Diagnosis and Plan of Care

The third step of the community nursing process is planning. At the beginning of this step, the team prioritizes identified health needs using methods described in the chosen CHA and community health improvement framework, model, or tool and determined by the team. The chosen health priorities are ones in which intervention would make the most impact, utilize community resources, and meet the community's needs. The community nursing diagnosis provides an explanation of the health need, aggregate, and factors that influence the health need. The CHIP is the nursing care plan for the community. It is developed in collaboration with community members and organizations to be used as a guide for community health intervention and programming.

available community resources to improve health; purpose of CHA and subsequent community health improvement plan is to identify key health needs of a community and to address those needs through strategic intervention

community health improvement plan (CHIP) a long-term systematic plan to address issues identified in the community health assessment that describes how the health department and the community will work together to improve population health

community partners all persons, agencies, and organizations who have an investment in the community's health and in the local public health system

education the establishment and arrangement of

events to facilitate learning and skill development
gap analysis analysis that is performed to identify and address the disparity between what is desired and real-world conditions

geographic information systems (GIS) software and technology that can store, visualize, analyze, and interpret spatial data

health indicators numerical measures of health outcomes, such as morbidity and mortality, that have been analyzed and are used to compare rates or trends of priority community health outcomes and determinants of health

learning the process of gaining knowledge and skills that lead to behavioral changes

organizational health literacy the degree to which organizations equitably enable individuals to find, understand, and use information and services to inform health-related decisions and actions for themselves and others

partnership relationship characterized by mutual cooperation and responsibilities among individuals and groups

personal health literacy the degree to which

individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others

primary data data collected by the assessor directly from community members; PHAB considers primary data to be data for which collection is conducted, contracted, or overseen by the health department

qualitative data data expressed in word form that cannot be quantified; describe perspectives of individuals and populations

quantitative data data expressed by amount in numerical terms

secondary data data obtained through existing reports on the community that were collected by another entity or for a purpose other than community health assessment

spatial data data that identify the geographic location of phenomena, provide an overview of the community in map form, and can be used to compare one part of the community to another

vital statistics population data about births, deaths, marriages, and divorces in the United States

Review Questions

- A nurse assesses a client's health literacy prior to providing education. The client is able to use interactive websites, identify multiple resources to gather health information, and assist others in health decision-making. Which health literacy level describes the client's skills?
 - Functional health literacy
 - Interactive health literacy
 - Critical health literacy
 - Organizational health literacy
- Which secondary data source would the public health nurse utilize to benchmark local health patterns to national (U.S.) patterns?
 - Healthy People 2030
 - Key informant interview
 - U.S. Census data
 - Focus group report
- Which community nursing diagnosis has the nurse written appropriately?
 - Ineffective coping related to multiple stressors as evidenced by the client crying and stating she has no support system
 - Risk of ineffective health maintenance among individuals who do not have access to a primary care provider
 - Risk of cardiovascular disease related to poor diet, sedentary lifestyle, and lack of access safe places to exercise
 - Risk of obesity among school-age children related to lack of access to healthy food choices and opportunities for physical activity
- Which of the following would the community health nurse include in an assessment of community systems?
 - Age, gender, and race
 - Water quality reports

- c. Health care providers
 - d. Morbidity patterns
5. A team is using the American Hospital Association Community Health Assessment (CHA) toolkit to conduct a CHA. They have defined the community and gathered data from multiple sources. According to the toolkit, what is the next step?
- a. Share results with the community
 - b. Prioritize community health problems
 - c. Evaluate progress
 - d. Plan implementation strategies
6. Which health literacy skill would the nurse anticipate in a client with functional health literacy skills?
- a. Understanding a prescription label
 - b. Following blood glucose trends
 - c. Recognizing personal health risks for cardiovascular disease
 - d. Following directions to reduce radon levels in the home
7. The nurse is developing a teaching plan for a client newly diagnosed with diabetes. Which action by the nurse focuses on the psychomotor domain of learning?
- a. Providing reinforcement for efforts toward self-care
 - b. Teaching about the relationship between insulin and blood glucose levels
 - c. Instructing the client on self-administration of insulin
 - d. Discussing the symptoms of hypoglycemia and hyperglycemia
8. Which action will the nurse take when utilizing constructivist theory to teach a community health education program about smoking cessation?
- a. Reward positive behaviors toward smoking cessation
 - b. Encourage reflection about smoking cessation
 - c. Model desired behaviors needed for smoking cessation
 - d. Assess knowledge to build upon what is already known about smoking cessation
9. Which method will the nurse use when teaching a client who is an auditory learner?
- a. Pictures and images
 - b. Videos
 - c. Interactive activities
 - d. Discussion
10. Which activity will the nurse perform during the continuously improve the community phase of the Mobilizing for Action through Planning and Partnership (MAPP) framework to improve the health of a community?
- a. Complete partner profiles
 - b. Strengthen community engagement
 - c. Perform Community Partners Assessment
 - d. Establish Community Health Improvement (CHI) leadership

CHAPTER 18

Planning Health Promotion and Disease Prevention Interventions

FIGURE 18.1 Families learn bike maintenance and safety and practice biking skills during a community program designed to increase physical activity through biking. (credit: modification of work “Morro Bay Bike Ed” by Bike SLO County/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 18.1 Theories and Models to Guide Program Planning
- 18.2 Partnerships and Coalitions in Program Planning
- 18.3 Developing Program Goals and Measurable Objectives to Demonstrate Outcomes

INTRODUCTION Jamie, a public health nurse, has been charged with planning an innovative, evidence-based program targeting children and families to promote physical activity. The county health department received grant funding to plan, implement, and evaluate a new physical activity program. A community health assessment (CHA) conducted before receipt of the grant indicated that the county has high adult and child overweight and obesity rates, low physical activity levels, sedentary lifestyles, and a lack of free physical activity resources. The CHA and community health improvement team have identified chronic disease–obesity as a major priority in the county. Assessment, diagnosis, and community-level planning have been completed. Jamie must now plan a program to meet the physical activity needs of children and families.

Nurses like Jamie develop community health programs to promote health and prevent disease. Effective programs are grounded in community assessment and health determinant data, target identified populations at risk, reduce health disparities and inequities, promote collaboration between groups invested in the community’s health, and incorporate evidence-based strategies. Theoretical frameworks and models support the program planning, implementation, and evaluation process.

18.1 Theories and Models to Guide Program Planning

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 18.1.1 Apply theoretical framework(s)/models to plan health promotion, disease prevention interventions, and illness management.
- 18.1.2 Combine knowledge of health determinants with data to plan health promotion and disease prevention interventions for communities and populations.
- 18.1.3 Assess learning needs across the continuum of care for self-care for health promotion, illness prevention, and illness management.
- 18.1.4 Examine different approaches to health promotion and disease prevention.

A **program** is an organized public health action or set of related activities undertaken to achieve an intended outcome (Centers for Disease Control and Prevention [CDC], 2023). The intended outcome meets the assessed needs of individuals, families, groups, populations, or communities to promote health and health equity, prevent illness, reduce health disparities, empower communities, and/or promote social justice. **Program planning** involves selecting and implementing activities to achieve desired health outcomes. It serves as a blueprint for coordinating resources to implement planned activities.

Program development follows an assessment of community health needs, identification of priority health problems, and diagnosis of specific community health problems. Community health programs should align with the health problems defined in the assessment phase, meet the community's perceived needs, target the at-risk aggregate identified during the analysis and diagnosis phases, and reduce characteristics of the community that contribute to risk factors listed within the community nursing diagnosis. [Assessment, Analysis, and Diagnosis](#) provides a guide to assessment, analysis, and diagnosis of population health programs.

Theoretical Frameworks and Models Used in Program Planning

In collaboration with the program planning team (those individuals and community partners who will provide resources, will implement or evaluate program activities, and will be impacted by the program), the nurse selects a theoretical framework or model to guide program planning. Theoretical frameworks and models provide a systematic method to develop, implement, and evaluate programs for health promotion, disease prevention, and illness management. CHA models, frameworks, and tools discussed in [Assessment, Analysis, and Diagnosis](#) include steps for planning programs. These models include comprehensive assessment guidance but do not include specific details to guide program planning. The Healthy Places by Design's community action model, PRECEDE-PROCEED model, PATCH model, and intervention mapping, described next, provide detailed guidance for program planning. A logic model is a tool used to visually represent a program.

Healthy Places by Design's Community Action Model

The [Healthy Places by Design Community Action Model \(<https://openstax.org/r/healthyplacesbydesign>\)](https://openstax.org/r/healthyplacesbydesign) describes six essential practices for sustained change within communities and outlines an intentional Partner, Prepare, and Progress, or "3P," Action Cycle. The program planning team considers community context and the six essential practices during all stages of the community action model to enhance the sustainability of actions that promote community health. These include the following:

- Health equity focus
- Facilitative leadership
- Culture of learning
- Strategic communication
- Sustainable thinking
- Community engagement

The 3P Action Cycle includes Partner, Prepare, and Progress stages. [Figure 18.2](#) describes tasks at each stage of the 3P Action Cycle and incorporates the six essential practices.

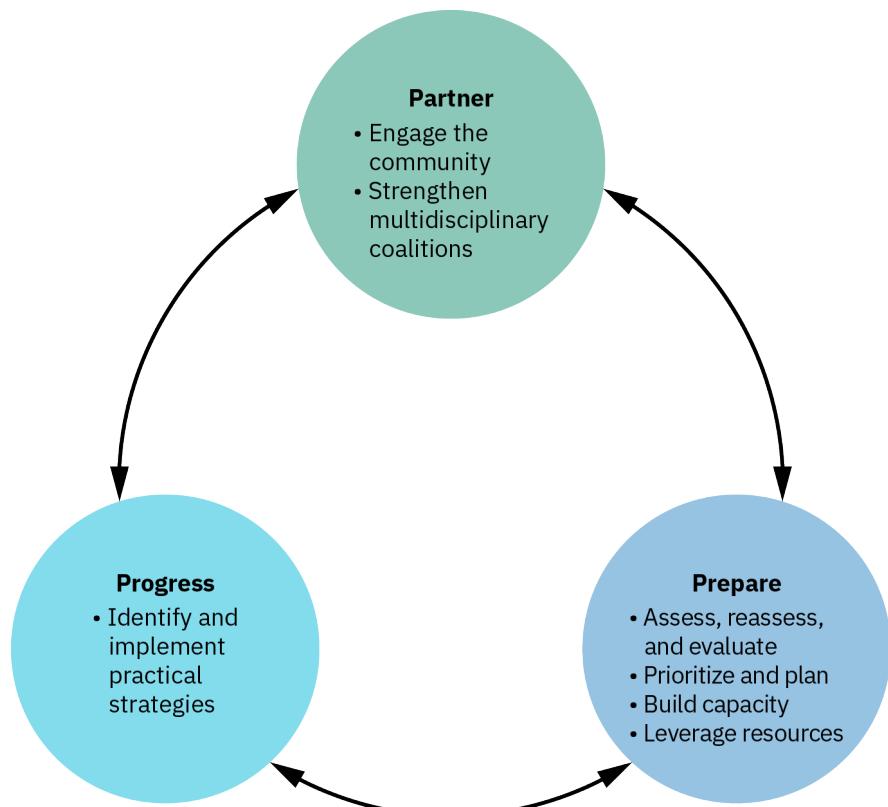

FIGURE 18.2 As part of the Healthy Places by Design's Community Action Model, the program planning team progresses through the 3P (Partner, Prepare, and Progress) Action Cycle to develop and implement community health programs. (See Healthy Places by Design, 2016; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

THEORY IN ACTION

Using the Community Action Model to Improve Infrastructure and Promote Physical Activity

The Tulane University Prevention Research Center established the KidsWalk Coalition to improve walking and bicycling infrastructure. The community program was developed, implemented, and evaluated using the community action model. The team used the 3Ps (Partner, Prepare, Progress) throughout the program.

Read the case study [Communities in Action: New Orleans, LA](https://openstax.org/r/healthycommunitiesin) (<https://openstax.org/r/healthycommunitiesin>), and then respond to the following questions.

1. How did the KidsWalk Coalition engage the community and strengthen multidisciplinary coalitions?
2. What policy and infrastructure progress did the KidsWalk Coalition make?

PRECEDE-PROCEED Model

The Green and Kreuter PRECEDE-PROCEED model considers social determinants of health and the community environment when planning programs for health promotion (Porter, 2016). PRECEDE stands for Predisposing, Reinforcing, Enabling Constructs in Educational/Environmental Diagnoses, and Evaluation. The four PRECEDE phases are discussed further in [Assessment, Analysis, and Diagnosis](#). PROCEED stands for Policy, Regulatory, and Organizational Constructs in Educational and Environmental Development. PROCEED follows the community assessment and identification of health issues, utilizing that information to guide program planning, implementation, and evaluation, and includes the following four phases:

1. Implementation: Design and implement the intervention.
2. Process evaluation: Evaluate the implementation procedure. Is what was planned actually being done?
3. Impact evaluation: Evaluate whether the intervention has the desired impact on the target population.
4. Outcome evaluation: Evaluate whether the intervention has produced the desired impact on the problem

identified in the PRECEDE phases.

The PROCEED model directs the user to choose an additional tool, such as the PATCH model, when designing interventions. The program team should select evidence-based interventions most likely to achieve program outcomes (Porter, 2016). [Implementation and Evaluation Considerations](#) further describes process, impact, and outcome evaluation.

Planned Approach to Community Health Model

The [Planned Approach to Community Health \(PATCH\) model \(<https://openstax.org/r/sophe>\)](#) builds on the PRECEDE model to provide a practical approach to community program planning (U.S. Department of Health and Human Services [HHS], 2001). PATCH includes a detailed guide and worksheets to use at each phase; these resources are especially helpful for communities that have little experience with assessment and program planning. PATCH describes five critical elements of community health promotion programming:

- Participation of community members
- Use of data to guide program development
- Development of a comprehensive health promotion strategy
- Evaluation to provide timely feedback and for program improvement
- Increase in community capacity for health promotion (HHS, 2001)

Capacity can be increased through relationships within the community, state health departments, universities, and other regional and national levels of organizations that can provide data, resources, and consultation. Capacity refers to the resources and relationships required to implement the program (Public Health Accreditation Board [PHAB], 2022). This chapter describes methods to develop these relationships.

PATCH can be used to plan, conduct, and evaluate health promotion and disease prevention programs and includes the following five phases:

1. Mobilizing the community
2. Collecting and organizing data
3. Choosing health priorities
4. Developing a comprehensive intervention plan
5. Evaluating PATCH

The first three phases relate to the CHA and community health improvement plan (CHIP) processes described in [Assessment, Analysis, and Diagnosis](#). The last two phases include development, implementation, and evaluation of community intervention for health promotion. When developing a comprehensive intervention plan, the team considers contributing factors and community-based programs currently being used elsewhere. This includes surveying other agencies and organizations and searching the literature and internet resources regarding current programs related to the identified community problem. PATCH recommends working with systems, such as schools, work sites, and hospitals, starting simple and combining educational, policy, and environmental strategies to enhance the program and make an impact in several ways.

Intervention Mapping

The Intervention Mapping (IM) framework provides a systematic approach to plan community health interventions. The initial steps of IM are based on the PRECEDE model (Fernandez et al., 2019). [Table 18.1](#) describes the six steps of IM and provides examples of tasks that Jamie, the nurse described in the chapter introduction, completed at each step with the program planning team in developing the Kenton Hardin County Family Bike Program (KHCFBP). Logic models, discussed in the next section, are typically used in IM.

IM Step	Tasks to Complete	Example of Tasks Completed by the KHCFPB Program Planning Team
Step 1: Logic Model of the Problem	<ul style="list-style-type: none"> • Establish a team consisting of the target population, individuals and groups impacted by the program outcome, and the planning and implementation team. • Conduct a CHA. • Perform analysis of health, quality of life, behaviors, and environmental conditions that influence health problems. • Create a logic model illustrating the problem. • Determine program goals. Goals are discussed in detail in Section 18.3. 	<ul style="list-style-type: none"> • Reviewed CHA, which showed that 70% of county adults were overweight or obese as defined by BMI, only 29% of adults met national physical activity recommendations, 15% of county youth were obese, and only 29% of youth met national physical activity recommendations. • The established team included staff from the county health department (director of nursing [DON], fiscal officer), a nurse educator, a YMCA staff member, the county WIC director, and two local bike experts. The team also collaborated with an established county transportation committee that had been looking to add bike paths in the community. • Determined program goal—to increase physical activity of program participants through biking and to increase bike safety.

TABLE 18.1 IM Steps and Associated Tasks

IM Step	Tasks to Complete	Example of Tasks Completed by the KHCFPB Program Planning Team
Step 2: Logic Model of Change	<ul style="list-style-type: none"> • Identify determinants of the identified health problem by searching the literature, choosing theories, and conducting research, if needed. • Select determinants to target during the program. • Determine expected outcomes and objectives. • Create a logic model of change. 	<ul style="list-style-type: none"> • Reviewed literature to locate evidence-based biking programs. • Identified determinants of biking: bike safety, biking skill, bike maintenance, and access to equipment. Also added nutrition to support physical activity. • Determined outcomes and objectives. Developing Program Goals and Measurable Objectives to Demonstrate Outcomes, Table 18.6 lists the objectives of the KHCFBP.
Step 3: Program Design	<ul style="list-style-type: none"> • Choose theory and evidence-based change methods. • Select or design program delivery methods. 	<ul style="list-style-type: none"> • Investigated several physical activity programs targeting youth and adults. Finding no biking program targeting youth and adults, the team designed the program based on five evidence-based programs. • Created logic model of the program.
Step 4: Program Production	<ul style="list-style-type: none"> • Draft messages, materials, and protocols. • Pretest, refine, and produce materials. 	<ul style="list-style-type: none"> • Created participant workbooks and facilitator guides with input from the nurse educator, DON, bike experts, and WIC director. • Added the county health department public relations staff to create advertisements. • Met with the team to review and refine the plan for implementation.

TABLE 18.1 IM Steps and Associated Tasks

IM Step	Tasks to Complete	Example of Tasks Completed by the KHCFPB Program Planning Team
Step 5: Program Implementation Plan	<ul style="list-style-type: none"> • Identify persons who are responsible for the delivery of the program. • State outcomes and performance objectives. • Implement the program. 	<ul style="list-style-type: none"> • Identified responsible persons. Bike experts delivered curriculum; volunteers assisted with biking skills and maintenance; DON and nurse educator managed logistics (surveys, forms, snacks, and equipment/time management). • Recruited volunteers from a local university to assist with program delivery. • Program was implemented.
Step 6: Evaluation Plan	<ul style="list-style-type: none"> • Develop evaluation indicators, measures, and questions. • Complete evaluation. 	<ul style="list-style-type: none"> • Used the CDC Framework for Program Evaluation in Public Health. • Created evaluations with input from the nurse educator, DON, bike experts, and WIC director. • Evaluated participant biking knowledge, helmet use, and amount of time riding prior to, immediately following, and 6 months after the program. • Conducted both process and outcome evaluations.

TABLE 18.1 IM Steps and Associated Tasks

Logic Models

Logic models are tools to visually present the relationships among resources that are used to implement a program, the activities planned, and the program's intended results (W. K. Kellogg Foundation, 2004). The logic model describes the sequence of events to connect the program's need with the desired results and shows how human and financial resources contribute to the program. The [Logic Model Development Guide \(<https://openstax.org/r/naccho>\)](https://openstax.org/r/naccho) provides a step-by-step method to create logic models. Common components of logic models include:

- Resources: human, financial, organizational, and community needed to operate the program
- Activities: processes, tools, events, technology, and actions for implementation
- Outputs: direct products of program activities, such as the number of participants
- Outcomes: specific changes in participant behavior, knowledge, or skill, usually designated by short-term and long-term
- Impact: fundamental change as a result of the program, usually within 7 to 10 years

[Figure 18.3](#) provides an example of a logic model developed by Jamie, the community health nurse described in the chapter introduction, and the program development team to visually represent the Kenton Hardin County Family Bike Program.

KHCFBP Logic Model

Situation: Hardin County has high rates of obesity and low rates of physical activity. Biking provides an avenue to increase physical activity and decrease obesity. Barriers to biking include lack of equipment, skill, knowledge, and confidence. Research shows reducing these barriers leads to increased biking frequency.

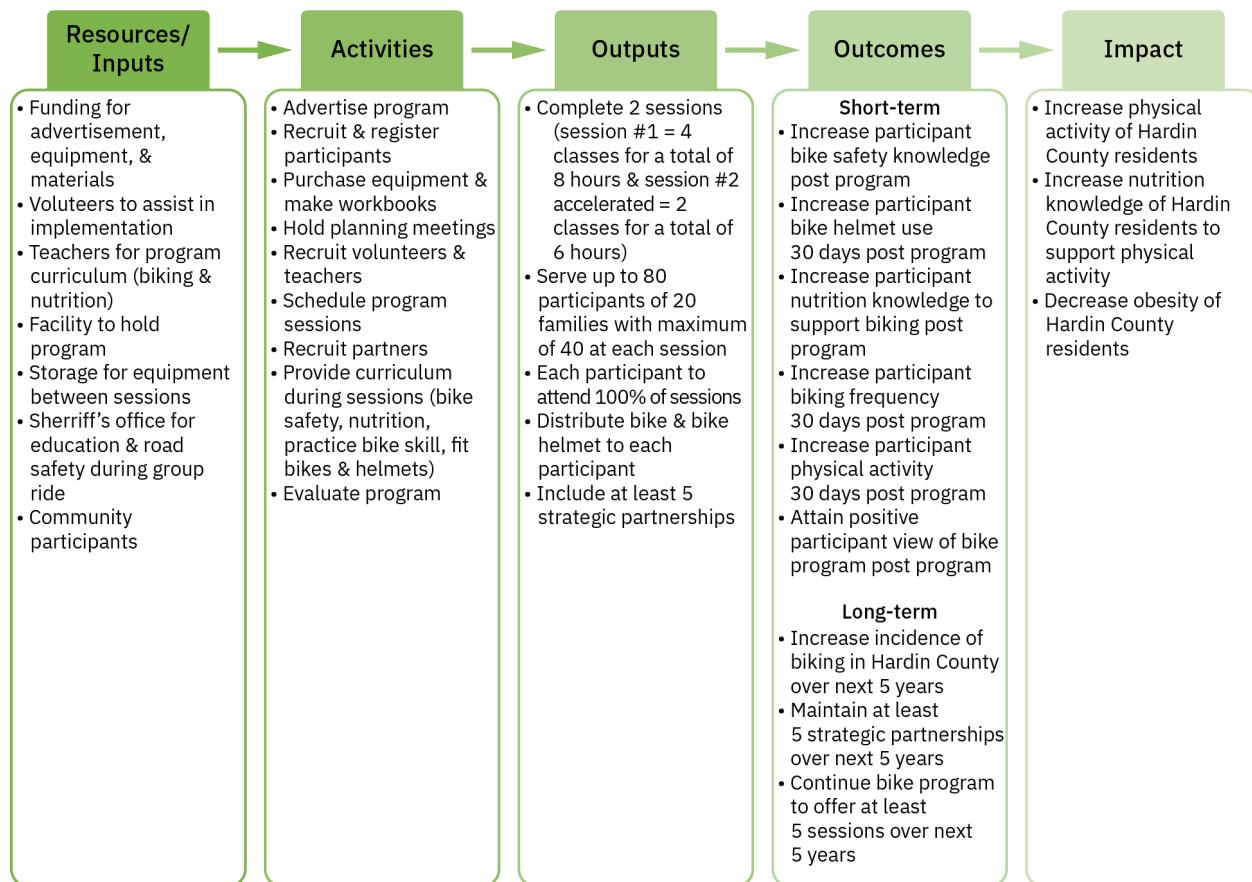

FIGURE 18.3 The community health nurse may assist in development of a logic model as a part of program planning. (source: reproduced with permission from Jamie Hunsicker, DNP, RN)

Use Health Determinants and Data to Plan Programs

Community assessment and health determinant data are the basis of effective programs. The first step of program planning, regardless of the framework or model selected, is to review community assessment data related to the identified problem that the program is targeting. This provides a rationale for implementing the program and establishes baseline data for measuring the health problem and evaluating the program.

The nurse also gathers data on determinants of health that contribute to the specific health problem. Determinants of health are combined factors that affect the health of individuals and communities, including individual characteristics and environmental conditions where people are born, live, learn, work, play, worship, and age (CDC, 2019; HHS, n.d.). As discussed throughout this text, those environmental conditions are called social determinants of health (SDOH). Individual determinants include age, sex, genetics, and behaviors, such as physical activity, nutrition, and substance use. SDOH include economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context (HHS, n.d.). Access to safe housing and transportation, employment opportunities, food security, income and socioeconomic status, level of education, air and water quality, and health literacy are all examples of SDOH. See [Social Determinants Affecting Health Outcomes](#) for more information.

THEORY IN ACTION

Addressing the Social Determinants of Health

[Access multimedia content \(<https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning>\)](https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning)

This animation describes the influence that SDOH have on health.

Watch the video, and then respond to the following questions.

1. How do social determinants of health impact health outcomes?
2. What are some community interventions the nurse could implement that would influence each determinant of health described in the video?

The nurse should incorporate health determinants into program planning for several reasons. First, SDOH account for 50 to 80 percent of health outcomes (Whitman et al., 2022; Zhang & Fornili, 2023). Health outcomes are strongly predicted by social and economic factors, followed by health behaviors, clinical care, and the physical environment (Hood et al., 2016). Poor social and economic conditions influence access to health care and an individual's ability to make healthy choices. For example, healthy food may be unaffordable or unavailable within the community. Additionally, individuals living in impoverished neighborhoods are more likely to experience an unsafe environment, low educational attainment, discrimination, and racism, all of which are associated with chronic stress. The constant release of stress hormones damages body systems and increases the risk of health problems. Second, federal health care programs and organizations have made addressing the SDOH a priority (De Lew & Sommers, 2022). The U.S. Department of Health and Human Services strategy to address the SDOH aims to improve

- data by increasing the collection of SDOH data and increasing data sharing among systems;
- connections between the health care systems, social services, and communities; and
- collaborations and partnerships among government organizations that impact health.

Finally, the nurse and program planning team direct program interventions toward reducing risk of disease. Because SDOH play a significant role in the development of disease, interventions should be directed at those SDOH impacting the community ([Figure 18.4](#)). Targeting several aspects of determinants of health enhances the likelihood that the program will achieve goals to reduce risk factors, promote health, and prevent illness.

In the KHCFBP example, the public health nurse, Jamie, and the bike program planning team identified determinants of physical activity via biking. Individual determinants of bike riding included motivation and confidence, knowledge of bike safety, and experience with biking and biking skill. Social determinants of bike riding included the ability to purchase bike equipment, the safety of sidewalks and streets, and social support (Hunsicker, 2020). In this instance, program planners decided to target all determinants except sidewalk and street infrastructure because the likelihood of influencing infrastructure changes was low during this program.

Factors Influencing Physical Activity in Communities

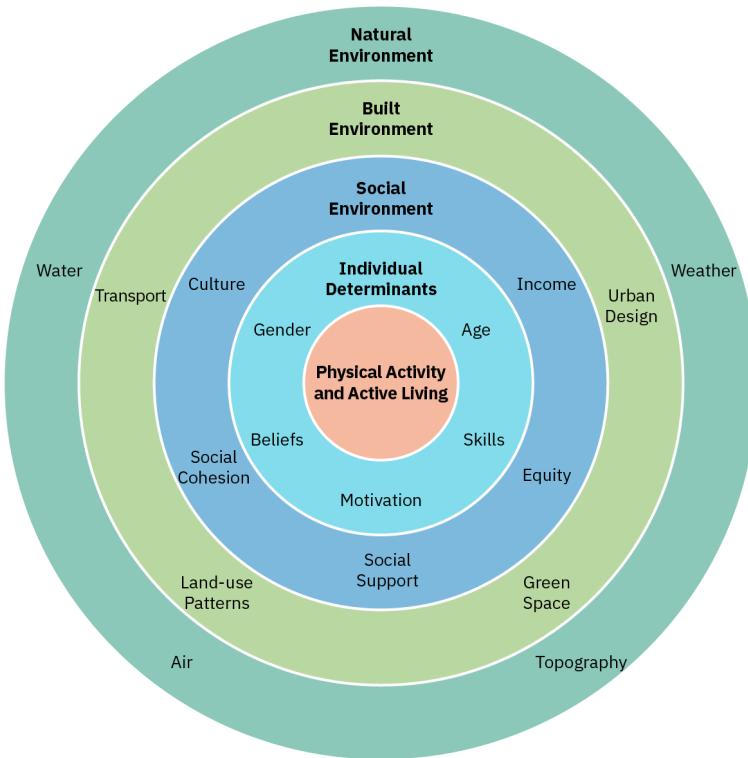

FIGURE 18.4 Determinants of physical activity include factors in the natural, built, and social environments such as weather, urban design, green space, and culture as well as individual determinants like motivation, beliefs, age, and skills. (See Dahlgren, 1995; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Assess Learning Needs Across the Continuum of Care

Effective and relevant community health programs aim to meet community needs by filling the gap between program participants' knowledge and what is known about a health problem. To understand learning needs, the nurse must assess the target population before the development of program activities. Learning assessments provide perspective regarding the community's educational needs and guide the choice of program activities to meet them. Therefore, assessment of learning needs and education is essential to community health programs.

THEORY IN ACTION

Using Health Education to Reduce Opioid Overdoses

[Access multimedia content \(<https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning>\)](https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning)

The Naloxone Education Empowerment Distribution (NEED) program was a successful program that has since been completed. It provided education to first responders, local pharmacies, and interested community members. The NEED program trained, certified, and provided community members with education and skills to successfully administer naloxone to prevent opioid overdose. Although it is not currently active, this evidence-based program can be revisited or used as an intervention to reduce opioid overdose deaths in the future.

Watch the video, and then respond to the following questions.

1. What learning needs do you think were identified before the implementation of the NEED program?
2. How do you think the assessment of learning needs led to the development of the program?

The nurse can use several methods to assess learning needs. The CHA provides an overview of community learning needs. A comprehensive CHA includes community perspectives via survey collection, focus groups or interviews, and statistical data on health outcomes. Analysis of this data gives the nurse a picture of the community's learning

needs. The nurse also assesses the target population's health literacy at both the community and participant level before program implementation, allowing the nurse to direct activities at the level of participant health literacy. Another method to assess the target population's learning needs is to include them in the program planning process. Members of the target population can provide their perspective, indicate what information is important to them, and clarify knowledge, skill, or attitude deficits. [Assessment, Analysis, and Diagnosis](#) discusses CHA and health literacy in more detail.

Approaches to Health Promotion and Disease Prevention

The nurse and program planning team consider health promotion and disease prevention theories during program development because these theories help explain health behavior and factors contributing to health problems. These theories direct the program planning team to choose interventions that support behavior change. The health belief model (HBM), transtheoretical model, and social cognitive theory (SCT) are common health promotion and disease prevention approaches used during program planning and implementation. [Health Promotion and Disease Prevention Strategies](#) provides a detailed overview of each theory. This chapter applies these theories to community nursing practice.

Application of the Health Belief Model

The nurse and program planning team use the health belief model (HBM) to design health promotion and disease prevention strategies. The HBM states that an individual is ready for health change if they

- believe they are susceptible to the health problem,
- believe the health problem has serious consequences,
- believe taking action will reduce their risk of the health problem,
- believe the benefits of change outweigh the costs,
- are exposed to factors that prompt change, and
- are confident in their ability to make a change.

The nurse and program planning team apply the HBM by first assessing the perceptions of the target population. This enables the team to develop activities that align with the population's needs. For example, if an individual or group does not believe they are susceptible to the health problem, the program would provide education on risks of the health problem. If an individual or group lacks confidence in their ability to make a change, the program would provide training to increase skill and confidence. For example, Jamie and the KHCFBP planning team aimed to increase participants' biking confidence and skill. They developed education on bike maintenance and safety and activities to practice biking skills to meet that aim.

THEORY IN ACTION

Applying the HBM in Community Programs

[Access multimedia content \(<https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning>\)](https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning)

Community health nurses used the HBM to plan and evaluate community health programs. The M-PACT, Men's Prostate Awareness Church Training, was a partnership between the local faith community, community members, and the Maryland School of Health. The project goal was to increase informed decision-making for prostate cancer screening among Black men who attend church.

Watch the video, and then respond to the following questions.

1. What were the needs and concerns of the Black men who participated in the program?
2. What specific activities did the M-PACT program use to meet participants' needs?
3. How did each activity correspond to the HBM?

Application of the Transtheoretical Model

The nurse and program planning team use the transtheoretical model to influence the change process. According to this model, individuals move through the following five stages when making health behavior changes:

- Precontemplation—no intention to make a change within the next 6 months
- Contemplation—intends to act within the next 6 months
- Preparation—intends to act within the next 30 days and has taken steps to plan for change
- Action—changes behavior for less than 6 months
- Maintenance—changes behavior for more than 6 months

The first step in applying the transtheoretical model to determine where participants fall within the five stages. The nurse and program planning team then develop activities that align with the stage of change. For example, if the program targets tobacco users in the precontemplation stage, activities would include personalized messages and education regarding the risks of tobacco use. If the program targets tobacco users in the preparation stage, activities would include assistance with setting attainable goals and education on resources to quit.

THEORY IN ACTION

Applying the Transtheoretical Model

[Access multimedia content \(<https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning>\)](https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning)

Community health providers use the transtheoretical model to determine individual readiness for change and interventions to match readiness for change. Most often this model has been used to assist individuals in quitting unhealthy behaviors, such as tobacco, alcohol, or other drug use, or to start healthy behaviors, such as exercise. The video applies the transtheoretical model to treatment of youth who use alcohol or other drugs (AOD).

Watch the video, review the [Treatment Matching Tip Sheet \(<https://openstax.org/r/dovetail>\)](https://openstax.org/r/dovetail), and then respond to the following questions.

1. What program activities align with individuals who have AOD problems in the preparation stage?
2. How is motivational interviewing used in the contemplation stage?

Application of Social Cognitive Theory

The nurse and program planning committee using social cognitive theory (SCT) recognize that the social environment influences health behaviors. SCT concepts include the following:

- Reciprocal determinism—interaction among the individual, behavior, and environment
- Behavioral capacity—knowledge and skill of the individual to perform a health behavior
- Expectations—anticipated outcomes of a behavior
- Self-efficacy—confidence in changing behavior and overcoming barriers to behavior
- Observational learning/modeling—watching another's behavior and outcomes leading to behavioral change
- Reinforcements—response to a behavior that increases or decreases the likelihood of that behavior

The first step in applying SCT involves assessing individual or group knowledge, skills, expectations, and confidence and the social environmental factors influencing the health problem. The program planning team plans activities to enhance participants' likelihood of adopting a new health behavior based on the SCT concepts. For example, a nutrition education program may model creating a healthy shopping list based on a budget, enhance participant confidence by having them participate in cooking classes, and reinforce healthy choices through verbal praise.

THEORY IN ACTION

Applying SCT to Reduce Risk of Obesity

[Access multimedia content \(<https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning>\)](https://openstax.org/books/population-health/pages/18-1-theories-and-models-to-guide-program-planning)

Community health providers recognize that health behaviors are influenced by the social environment. Los Angeles Universal Preschool uses SCT to teach healthy habits with the aim of reducing childhood obesity in low-income minority preschool populations.

Watch the video, and then respond to the following questions.

1. What determinants of obesity did the preschool teacher influence through purposeful intervention?
2. What interventions highlight the concepts of SCT?

18.2 Partnerships and Coalitions in Program Planning

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 18.2.1 Differentiate between partnerships and coalitions.
- 18.2.2 Identify impacted individuals or groups and mobilize community partnerships to solve health problems within programs, communities, and populations.
- 18.2.3 Demonstrate the ability to engage with other health professionals and community partners through social networking.
- 18.2.4 Organize team and community partners with a shared vision, values, principles, and capacity for community action.
- 18.2.5 Discuss the ethical considerations associated with planning, implementing, and evaluating health programs.

The nurse uses a participatory approach during the development, implementation, and evaluation of effective and relevant community health promotion and disease prevention programs. A participatory approach enables and empowers community members to be actively involved in decisions throughout the program planning, implementation, and evaluation process. The nurse invites individuals or groups who are impacted by a health problem and/or are impacted by a community health program to become involved. The nurse engages community members, agencies, and organizations to enhance program planning by sharing ideas, resources, and work. The community health program is based upon mutual vision, values, principles, and capacity.

Community Partnerships and Coalitions

Community engagement is an essential component of program planning. Community engagement is the process of working collaboratively with and through groups of people to identify the health needs of community residents and strategies to address them. Any person, agency, or organization that is invested in the community's health and in the local public health system or is impacted by the outcomes of community health programs should be considered a potential partner. The nurse develops a list of potential partners during the first stages of program planning. [Table 18.2](#) lists potential community partners to consider when planning community health programs (U.S. Department of Housing and Urban Development [HUD], 2012; World Health Organization [WHO] & UNICEF, 2022).

Individuals	Agencies and Organizations	Government
<ul style="list-style-type: none"> • Health care providers • Nurses • Experts in the problem • Community members • Populations of interest • Researchers • Community leaders • Elected officials • Donors 	<ul style="list-style-type: none"> • Mental health agencies • Hospitals and health care systems • Social service agencies • First responders (fire, EMS, police) • Schools • Universities • Media • Preschools and childcare agencies • Medical clinics • Housing agencies • Philanthropic foundations • Faith-based organizations • Libraries 	<ul style="list-style-type: none"> • County officials • Public health departments • Policymakers

TABLE 18.2 Potential Partners for Community Health Programs

A partnership is a relationship characterized by mutual cooperation and shared responsibilities among individuals

and groups with a common focus that combine resources to implement joint activities (PHAB, 2022). For example, the local public health department, WIC, the local health system, and the YMCA combine efforts to hold a mom-baby fair (Figure 18.5). The public health department provides car seat education and new car seats. WIC provides nutrition education and resources for healthy foods. The local health system provides education on immunizations and safe sleep. The YMCA offers education on mom-baby exercise classes. Each organization also contributes baby items for raffle.

FIGURE 18.5 A community health nurse partners with local organizations, such as WIC, to provide education to expecting and new parents during a health fair. (credit: FNS Midwest/Flickr, Public Domain)

Partnerships may expand into a **coalition**. A coalition is a group of people and organizations that work to address community needs and solve community problems (PHAB, 2022). Coalitions connect multiple sectors within the community, such as schools, worksites, government, public health, hospital systems, community-based organizations, religious organizations, and the community at large (Society for Public Health Education [SOPHE], 2016). Coalitions help gain attention for the health problem; share knowledge, strategies, risks, and responsibilities; combine resources to address the health problem; assemble diverse talents and expertise; limit duplication of programs and services; and attain sustainability for health programs (Issel & Wells, 2018; SOPHE, 2016). Coalitions are strategic, formed in response to a specific health problem. For example, the program discussed in [Theory in Action: Using the Community Action Model to Improve Infrastructure and Promote Physical Activity](#) was accomplished by a coalition (Healthy Places by Design, 2016). The KidsWalk Coalition included members from schools, businesses, government agencies, youth organizations, community and faith-based organizations, and the New Orleans Department of Public Works. The specific health focus was to improve infrastructure and safety to make walking and biking an option for community members.

Engage and Mobilize Community Partnerships

The nurse identifies and engages potential community partners and develops community partnerships before developing strategies for community health promotion and disease prevention programs. [Table 18.3](#) describes the eight action steps and related activities the nurse uses to engage potential partners, mobilize community partnerships, and create community health coalitions.

Action Steps	Activities
1. Identify potential partners.	<ul style="list-style-type: none"> List potential individuals and organizations who may have an interest in or are impacted by the program or health issue. Check the list to ensure diversity. Conduct a partner analysis and community asset mapping.
2. Engage potential partners.	<ul style="list-style-type: none"> Contact potential partners to clarify partner analysis and community asset mapping. Clarify and determine the alignment of vision, values, capacity, goals, and objectives of each partner. Establish mutually beneficial partnerships. Build trust among partners and within the community.
3. Develop a partnership agreement.	<ul style="list-style-type: none"> Determine the roles and responsibilities of each partner. Establish a formal or informal agreement.
4. Determine program priorities.	<ul style="list-style-type: none"> Establish a shared purpose, including vision, values, and principles. Develop goals and objectives.
5. Develop an action plan.	<ul style="list-style-type: none"> Develop strategies, resources, timeline, and budget. Determine work groups, if needed, to implement strategies. Develop evaluation strategies.
6. Implement strategies.	<ul style="list-style-type: none"> Implement planned strategies. Communicate progress to all partners. Revise strategies as needed.
7. Evaluate the coalition and strategies.	<ul style="list-style-type: none"> Conduct planned evaluation. Revise coalition structure as needed. Revise action plan as needed. Build on successes and expand strategies as needed. Disseminate results to all partners and the community.
8. Determine future as a partnership or coalition.	<ul style="list-style-type: none"> Complete initial strategies. Determine if the relationship will be permanent, will transfer to another leadership structure, or will dissolve. Create new goals and objectives if the relationship continues.

TABLE 18.3 Steps to Engage Community Partners and Create Coalitions (See HUD, 2012; John Snow Inc. [JSI], 2014; SOPHE, 2016; WHO & UNICEF, 2020.)

Identifying and engaging potential partners, which occurs in Steps 1 and 2, can be daunting, especially when there are few established partnerships and coalitions within the community. The nurse uses **social networks** to effectively engage potential partners. Social networks are linkages among individuals, groups, and organizations that arise out of geographical location, work relationships, school relationships, or recreational activities (Dozier et al., 2015). The nurse utilizes personal social networks to understand the individual, group, and organization's health priorities, recruit those with similar priorities, and solicit suggestions for other potential partners interested in the program. Social media provides an additional method to identify and engage potential partners. Social media is an effective engagement method in that it can be used to do the following (Walsh et al., 2021):

- Search for individuals and community groups who post related content, such as health information and resources, policy advocacy, and discussions related to the targeted health problem
- Disseminate information and program needs related to the targeted health problem
- Expand reach to recruit community members from diverse groups and the target population
- Provide a method to enhance communication among partners and coalitions by forming social media groups

Strategies to identify and engage potential partners more effectively include considering a potential partner's activities, accomplishments, current and potential contributions to health, individual and organizational self-interests, and possible conflicts (SOPHE, 2016). Partnerships and coalitions are more likely to succeed if specific interests and goals align and they can realistically achieve activities with minimal expense (HUD, 2012; Issel & Wells, 2018). Additionally, each partner should have a return on investment, benefiting from the partnership (HUD, 2012). The time and resources spent engaging in partnerships and relevant activities should help each partner meet their organization's goals.

Community asset mapping and partner analysis assist the nurse in identifying potential partnerships. Community asset mapping includes all community sectors with resources that could be utilized. The nurse completes an inventory of assets and the type of activities that potential individuals, organizations, or associations are engaged in. Assets may include the following (HUD, 2012):

- Human resources, such as number, expertise, talent, and skills of staff
- Physical resources, such as location to target population, public spaces, and meeting rooms
- Information resources, such as educational materials and access to information resources
- Political resources, such as elected officials and advocacy for policy change
- Existing program resources, such as a program that has already been implemented

Partner analysis uses that information to describe an organization's experience with program planning and implementation, knowledge and expertise, available resources, influence on other partners, and potential roles and responsibilities for the program (WHO & UNICEF, 2020). JSI (2014) created a [toolkit for partnership, collaboration, and action](https://openstax.org/r/publications) (<https://openstax.org/r/publications>) that provides tools to evaluate organizational readiness, identify barriers and challenges for partnerships, evaluate potential partners, and evaluate collaborative practices.

During Step 3, the nurse develops partnership agreements with established partners. The partnership agreement may be a formal written agreement, such as a legal contract or Memorandum of Agreement (MOA), or an informal verbal contract. The best approach is a written agreement, reviewed annually, that contains enough detail to evaluate whether each partner fulfilled their partnership commitment (JSI, 2014). This legally protects all partners' best interests. JSI (2014) developed the [Partnership Agreement Development Tool \(PAD\)](https://openstax.org/r/publicationsjsi) (<https://openstax.org/r/publicationsjsi>) to assist in developing a partnership agreement. The tool directs partners to address roles and responsibilities of each party in the relationship.

Strategies to assist the nurse during Step 4, determine program priorities, and Step 5, develop an action plan, are described in sections below.

Organize Teams with Shared Vision, Values, Principles, and Capacity for Community Action

The nurse is aware that **team dynamics** influence effective collaboration of partners during community program planning. Team dynamics refers to the relationships, interactions, attitudes, and behaviors that arise when a group of individuals work together. Positive team dynamics, such as open communication, conflict resolution, alignment of roles, commitment to the project, and optimism, improve both team and individual performance and enhance effectiveness to reach team goals (Sharma, 2023).

TEAM SCIENCE: THE EFFECTIVE TEAM

[Access multimedia content](https://openstax.org/books/population-health/pages/18-2-partnerships-and-coalitions-in-program-planning) (<https://openstax.org/books/population-health/pages/18-2-partnerships-and-coalitions-in-program-planning>)

Healthy team dynamics enhance a teams' ability to communicate effectively, make decisions, and accomplish shared goals.

Watch the video, and then respond to the following questions.

1. What are characteristics of a healthy team?
2. Why is setting team expectations important when working with a group?
3. What are factors that make a team successful?

The nurse, partners, and other interested parties meet to develop a shared vision, values, principles, and capacity to clarify the team's common interests and provide purpose, focus, and direction for program planning. A program **vision** is a statement that articulates the desired goals that the planning team aspires to achieve (HUD, 2012; PHAB, 2022). The vision should include diverse perspectives and be broad, inspiring, and easy to communicate (HUD, 2012). For example, the North Carolina Farmworker Health Program (NCFHP, 2023) [vision statement](https://openstax.org/r/ncdhhs) (<https://openstax.org/r/ncdhhs>) directs collaboration with local agencies to meet farmworkers' health needs:

We envision a comprehensive network of health care professionals that provides culturally appropriate and accessible health services, empowering farmworkers and their families to live healthy lives as valued members of informed and inclusive communities.

When writing the program vision, the team answers the following questions:

- What is the problem we are attempting to solve?
- What are we hoping to achieve?
- If we achieved all the goals, what would the community look like in the future?

A program's **values** flow from the vision. Values are the core principles and beliefs that direct the team (PHAB, 2022). When writing the program values, the team answers the following questions:

- What shared values are unique to our team?
- What behaviors do we value that are related to the problem, health promotion, and disease prevention?
- How will we implement our program activities to achieve our vision?

Although program documents may not explicitly note values, they are interwoven throughout activities and demonstrated in the program's practices. For example, values evident in the NCFHP are health equity, cultural and linguistic competency, collaboration, access, and empowerment.

Finally, the nurse, partners, and other interested parties define the program's capacity. When determining program capacity, the team answers the following questions:

- What resources can each partner and interested party contribute to the program?
- Are there other resources in the community that could be utilized?
- Is additional funding available, such as state or federal grant opportunities or community donors?
- Are there other community relationships that could be established to increase capacity?
- Are there barriers related to resources and relationships?

CONVERSATIONS ABOUT CULTURE

Cultivating Care

[Access multimedia content \(<https://openstax.org/books/population-health/pages/18-2-partnerships-and-coalitions-in-program-planning>\)](https://openstax.org/books/population-health/pages/18-2-partnerships-and-coalitions-in-program-planning)

A community health program is developed according to the vision, values, and capacity of partners and other interested parties planning and implementing the program. The NCFHP demonstrates the incorporation of vision, values, and capacity by assisting local agencies in increasing access to health and dental care for farmworkers and their families.

Watch the video, and then respond to the following questions.

1. What barriers to accessing health care did the migrant workers face? How did the NCFHP address them?
2. How has the NCFHP vision impacted program activities?
3. How are values incorporated into NCFHP activities?
4. How does the NCFHP build capacity?

Ethical Considerations Associated with Planning, Implementing, and Evaluating Community Programs

The program team must consider community health ethical principles and issues associated with program planning, implementation, and evaluation. Ethical and moral norms related to health care and community health are considered when planning program activities. The American Public Health Association (APHA, 2019) [Public Health Code of Ethics](https://openstax.org/r/apha) (<https://openstax.org/r/apha>) provides an overview of ethical norms to consider. Accountability, participant protection, and incentive use are specific ethical topics that influence program planning decisions. Program planning, implementation, and evaluation teams are responsible for ensuring ethical and moral norms are upheld. Ethical analysis should occur in the beginning stages of program planning.

Ethical and Moral Norms

The nurse and program team follow the Public Health Code of Ethics during program planning, implementation, and evaluation. [Table 18.4](#) provides a description and application of ethical and moral standards that should be incorporated into program development and implementation.

Ethical Standard	Examples of Application
Professionalism and trust	<ul style="list-style-type: none"> Evidence from research and experience supports actions (APHA, 2019). Program and activities have been shown to improve health practice and outcomes (APHA, 2019). Program and program team are competent, honest, transparent, and accurate (APHA, 2019). Secondary interests do not influence program choices (APHA, 2019).
Health and safety	<ul style="list-style-type: none"> Program and activities promote health and well-being, minimize harm, prevent disease, and promote safety (Akrami et al., 2018; APHA, 2019).
Health justice and equity	<ul style="list-style-type: none"> Program and activities equally distribute burdens, benefits, and opportunities for health (Akrami et al., 2018; APHA, 2019). Program and activities do not exacerbate health inequity, including structural and institutional inequity (APHA, 2019). Program and activities reduce social inequities (Akrami et al., 2018).
Interdependence and solidarity	<ul style="list-style-type: none"> Program and activities foster positive relationships within the community (APHA, 2019).
Human rights and civil liberties	<ul style="list-style-type: none"> Program participants have the right to personal autonomy, self-determination, and privacy (Akrami et al., 2018; APHA, 2019).
Inclusivity and engagement	<ul style="list-style-type: none"> Program engages individuals and communities affected by decision-making (APHA, 2019). Decision-makers represent diverse community individuals, partners, and organizations (APHA, 2019). Program empowers the community to make informed decisions and health changes (Akrami et al., 2018).

TABLE 18.4 Ethical and Moral Norms to Consider During Program Planning, Implementation, and Evaluation

▶

WHAT IS HEALTH EQUITY?

Access multimedia content (<https://openstax.org/books/population-health/pages/18-2-partnerships-and>-

[coalitions-in-program-planning\)](#)

Unequal access to resources leads to health disparities. Health disparities are health differences that negatively affect socially disadvantaged populations. Public health programs focus on eliminating health disparities by promoting health equity and health justice. Health equity gives individuals what they need to achieve equal health outcomes. Health justice is one method to achieve health equity and involves eliminating personal, community, political, and systematic barriers to equitable health outcomes. This video discusses causes of health inequity and provides recommendations to achieve health equity.

Watch the video, and then respond to the following questions.

1. What causes health inequity?
2. What does the American Public Health Association recommend to reduce disparities and promote health justice and equity?

Accountability

The nurse and program team consider professional and program accountability during partnership establishment, program planning, program intervention, and program evaluation. Professional accountability ensures that team members act within the scope of their professional license. Additionally, individuals within the team should have the appropriate training, skill, and supervision to ensure that the services and activities offered are the best available. For example, Jamie (the nurse) and the KHCFBP team asked a local bike expert and licensed educator to assist with activity planning and content delivery. This ensured that the right individual, with the needed knowledge, skill, and experience, was involved.

The nurse and program team consider program accountability when developing the program's vision, values, and activities. The program is accountable for upholding community health program standards, such as implementing activities that originate from health needs of the community, are delivered with efficient use of resources, reach the intended population, have been delivered as planned, are managed according to the planned budget, make the most impact, and follow local, state, and federal law (Issel & Wells, 2018). The program must be fiscally responsible, including efficient and appropriate use of funds. For example, funds that were donated to purchase bikes and bike helmets for a community health biking program must be used for that purpose. It would be unethical to use those funds in any other way. Finally, program accountability includes transparency, commitment, and sustainability of services (Akrami et al., 2018). The program should be implemented as promised and continue for as long as promised. For example, if a program offers free screening to community members, the program should have the resources to provide screening to all who qualify.

Participant Protection

Participants' privacy and autonomy should be protected throughout program implementation and evaluation. Community program participant information is only confidential by law under certain circumstances, such as the Health Insurance Portability and Accountability Act (HIPAA) for health care systems and the Family Educational Rights and Privacy Act (FERPA) for educational systems (Issel & Wells, 2018). Even if the community program does not fall within those categories, best practice is to only allow access to participants' personal information for those working directly with participants or within reports required for funding purposes. At the beginning of the program, the nurse communicates circumstances where the team may share personal information and may attain informed consent for sharing of information.

Participant autonomy is protected through disclosure and informed consent. The nurse discloses program conditions and activities, conflict of interest, policies regarding confidentiality, and if the program is a part of a research study. The participant also has the choice to participate in and withdraw from the program at any time. If the program is part of a research study, Institutional Review Board (IRB) approval must be gained, and participants must consent to participate in the study. The IRB reviews evaluation and research plans to ensure ethical standards are followed and participant rights are protected. Consent includes ensuring participant understanding of the purpose of the study. Autonomy and informed consent issues arise in community health programs because many programs target vulnerable populations and children (Issel & Wells, 2018). Care must be taken in these situations to ensure that ethical standards are followed.

Incentive Use

Using **incentives** in community health programs has been a highly debated topic. Incentives are used to motivate program participants to do something. Community health programs may use incentives to increase program enrollment and retention or adoption of health promotion and disease prevention behaviors. Four types of incentives have been used in community health programs (CDC, 2021):

- Cash incentives: providing cash to a person or direct depositing funds into a bank account
- Noncash financial incentives: providing items that have cash value, such as gift cards, vouchers, or insurance premium discounts
- Nonfinancial incentives: providing items that have value, but not cash value, such as prizes, products, or memberships
- Mixed incentives: providing a combination of above

Incentives reward behavior in the short-term, which people most often prefer, and so increase the likelihood of behavior in the short-term (CDC, 2021). Incentives may also provide motivation to adopt a healthy behavior, but this depends upon the complexity of the behavior change (CDC, 2021). For example, an incentive for simple behaviors, such as attending a meeting for weight loss, may be more successful than an incentive for complex behaviors, such as losing 20 pounds. Complex behaviors take more time, effort, and consistent change than simple ones, so the incentive may not align with the complexity. Programs that use incentives have been found to have higher levels of attendance and increased adoption of health behaviors compared to those that do not, but these results have varied according to race (CDC, 2021). Because of this, it is important to include members of the target population in decision-making regarding incentive use.

Factors to consider before adoption of the use of incentives include the following (CDC, 2021):

- Program setting and participants—Types of incentives may work in some settings and populations but not in others.
- Maintenance of change—Behaviors may not continue when incentives have stopped, so strategies to maintain behavior change should be incorporated into the program.
- Incentive type, amount, and frequency—Determine whether to use financial or nonfinancial incentives and how much incentive is needed to motivate participants as well as how often incentives will be given.
- Measurement method—Decide whether to provide incentives only for behaviors that can be measured rather than those that require self-reporting.

Ethical Analysis of Community Programs

The nurse appraises community programs to ensure ethical norms are maintained. The APHA (2019) offers a list of questions that can be used to analyze the ethics of a community program. [Table 18.5](#) lists ethical standards and associated questions.

Ethical Standard & Description	Example of Question for Assessment
Permissibility <ul style="list-style-type: none"> • Socially and culturally appropriate • Within the standard of the law 	<ul style="list-style-type: none"> • Is the action (program or program activity) ethically wrong, even if the action's outcome is good?
Respect <ul style="list-style-type: none"> • Supports human dignity within transactions, exchanges, and relationships • Relates to values of justice, equity, interdependence, and solidarity 	<ul style="list-style-type: none"> • Is the action (program or program activity) demeaning or disrespectful to individuals or communities, even if it benefits health?

TABLE 18.5 Assessment of Ethical Standards in Community Programs (See APHA, 2019.)

Ethical Standard & Description	Example of Question for Assessment
Reciprocity <ul style="list-style-type: none"> • Cooperation and mutual exchange • Reasonable burden 	<ul style="list-style-type: none"> • Does the action (program or program activity) outweigh the potential harm and loss that is imposed on individuals and communities?
Effectiveness <ul style="list-style-type: none"> • Achievement of the intended public health goal 	<ul style="list-style-type: none"> • Is it expected that the action (program or program activity) will achieve its stated goals based on evidence and experience?
Responsible use of resources <ul style="list-style-type: none"> • Resources such as human skill, expertise, and time; equipment and supplies; natural resources; infrastructure; and funds 	<ul style="list-style-type: none"> • Does the action (program or program activity) show efficient and effective use of resources that could be used for other actions?
Proportionality <ul style="list-style-type: none"> • Equitable and fair • Does not benefit one group more than another • Decreases inequities and disparities 	<ul style="list-style-type: none"> • Are the program planners, implementers, and evaluators using power and authority appropriately? • Does the action (program or program activity) distribute costs and benefits in an equitable, fair, and nondiscriminatory way? • Does the action (program or program activity) benefit few and cause harm to many?
Accountability and Transparency <ul style="list-style-type: none"> • Builds trust with individuals and communities • Demonstrates respect for affected communities and partners 	<ul style="list-style-type: none"> • Do the program planners, implementers, and evaluators provide a rationale for the action (program or program activity)? • Has the action (program or program activity) been analyzed ethically and determined to be ethical?
Public participation <ul style="list-style-type: none"> • Meaningful involvement of members of the public • Ensures participants and decision-makers are mutually informed and engaged in dialogue and exchange 	<ul style="list-style-type: none"> • Have partners and community members had the opportunity to participate in decision-making?

TABLE 18.5 Assessment of Ethical Standards in Community Programs (See APHA, 2019.)

18.3 Developing Program Goals and Measurable Objectives to Demonstrate Outcomes

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 18.3.1 Differentiate between goals, objectives, and outcomes.
- 18.3.2 Utilize Healthy People 2030 national goals and measurable objectives to guide evidence-based policies, programs, and other actions to improve health and well-being.
- 18.3.3 Create an action plan inclusive of mutual goals and measurable objectives, considering strategic plans and evaluation methods.

The final steps of program planning include creating goals, objectives, outcomes, and an action plan. The nurse and program planning team use Healthy People 2030 national goals and other measurable objectives to guide actions. The goals, objectives, outcomes, and action plan align with the program's vision, values, and capacity.

Goals, Objectives, and Outcomes in Program Planning

The nurse and program team create goals, objectives, and outcomes before developing the action plan. **Goals** are statements that explain the program's purpose and what the program plans to accomplish (Division for Heart Disease and Stroke Prevention [DHDSP], 2018; Substance Abuse and Mental Health Services Administration [SAMHSA], 2018). Goals align with the identified health problem, vision, and program values. Goals are achieved through program objectives and activities. For example, the overarching goal of the KHCFBP, mentioned throughout the chapter, was to increase physical activity of adults, adolescents, and children through biking.

Objectives are statements of specific actions or behaviors that lead to accomplishing program goals (DHDSP, 2018; SAMHSA, 2018). Objectives should be specific, measurable, achievable, relevant, and time-bound (SMART) in order to provide clarity, establish accountability, focus timing, communicate realistic expectations, and direct evaluation (DHDSP, 2018). SMART objectives can be short-term, intermediate, or long-term and can be related to process or outcomes. **Process objectives** direct activities to be completed in a specific time frame and describe participants, interactions, and activities (DHDSP, 2018). **Outcome objectives** state the intended results of activities or the program, focusing on changes in knowledge, skills, and attitudes of participants and community members or in policies, systems, or environments (DHDSP, 2018). For example, the KHCFBP team wrote objectives to provide clarity, accountability, and focus for the program activities. [Table 18.6](#) provides examples of short-term, intermediate, and long-term objectives based on the KHCFBP goals.

KHCFBP Goal

Increase physical activity of adults, adolescents, and children through biking.

Increase adult, adolescent, and child knowledge, skill, confidence, and safety associated with biking.

Process Objectives	By August 31, 2018, complete two sessions of the KHCFBP.
	By August 31, 2018, reach up to 80 parents/guardians, adolescents, and children participating in the KHCFBP.
	By August 31, 2018, 100 percent of participants will attend and complete all planned activities.
	By August 31, 2018, form at least five strategic partnerships in program planning, implementation, and/or evaluation.
	By August 31, 2018, distribute one bike and one bike helmet to each program participant.
Short-term Outcome Objectives*†	By the end of each session (July 14, 2018, or August 25, 2018), increase participant bike safety knowledge from pre-program to post-program.
	By the end of each session (July 14, 2018, or August 25, 2018), attain a positive participant view of the bike program.
Intermediate Outcome Objectives*	By 30 days post-program (August 13, 2018, or September 24, 2018), increase participant bike helmet use from pre-program.
	By 30 days post-program (August 13, 2018, or September 24, 2018), increase participant biking frequency from pre-program.
	By 30 days post-program (August 13, 2018, or September 24, 2018), increase participant physical activity from pre-program.
Long-term Outcome Objectives*	By August 31, 2023, increase physical activity of Hardin County youth from 29 percent meeting national physical activity goals of at least 60 minutes daily to at least 32 percent.
	By August 31, 2023, maintain at least five strategic partnerships gained with the KHCFBP.
	By August 31, 2023, offer at least five additional sessions of the KHCFBP.

TABLE 18.6 Examples of the KHCFBP's Process Objectives and Short-Term, Intermediate, and Long-Term Outcome Objectives

*Use baseline data if possible. The KHCFBP was a new program, so no baseline data were available for short-term and intermediate objectives.

†Physical activity was chosen in this case because biking frequency is not measured in county community health assessment.

Writing SMART Objectives

The SMART method is one approach to ensure that the objectives of community health programs are well-written. Well-written objectives answer “WHO is going to do WHAT, WHEN, and TO WHAT EXTENT?” (DHDSP, 2018, p. 2). The SMART method is used to determine whether the program has achieved what it intended (see [Table 18.7](#)).

S	Specific	Identifies the target population or setting and actions
M	Measurable	Identifies what will be measured and includes baseline data if available
A	Attainable/ Achievable	Evaluates the feasibility of achievement in relation to available resources, time frame, and support
R	Relevant/Realistic	Relates the relationship between the objective and overall goal
T	Time-bound	Identifies a reasonable and achievable time frame for accomplishment

TABLE 18.7 Objectives Using the SMART Approach

The nurse and program team use baseline data to determine change, so it is included within the objective. Baseline data can be local information, such as data gathered during community health assessment, or state or national information, such as data within state health assessment reports, national health data sites, or Healthy People 2030. [Assessment, Analysis, and Diagnosis](#) discusses methods for gathering baseline data. When baseline data is not available, it should be stated that baseline data will be gathered as a first activity of the program (DHDSP, 2018).

The nurse and program team determine relevancy and reasonableness by gathering evidence for program activities. Literature, best practice, and theory provide rationale that the objective, and activities stemming from the objective, directly lead to change (DHDSP, 2018). DHDSP (2018) has developed a [guide for writing SMART objectives \(<https://openstax.org/r/cdcprograms>\)](#) that can be used by the nurse and program team.

Healthy People 2030 in Program Planning

The nurse and program team can use [Healthy People 2030 \(<https://openstax.org/r/healthyp>\)](#) to establish a baseline for measurement, align objectives with national leading health indicators and priorities, address SDOH, and find evidence-based resources to address identified community health problems. Healthy People 2030 includes evidence by topic related to health conditions, health behavior, population, setting and system, and social determinants of health. It also includes Healthy People in Action posts to describe how communities are implementing evidence-based programs based on Healthy People 2030 goals and objectives. This evidence provides a rationale for the choice of community health program goals, objectives, outcomes, and activities.

HEALTHY PEOPLE 2030

Physical Activity: Evidence-Based Resources

Healthy People 2030 provides national goals and objectives and evidence-based resources for action. Review the Healthy People 2030 [physical activity objectives \(<https://openstax.org/r/healthypeopleobjectives>\)](#) and resources to see examples of current national goals and the 31 evidence-based resources related to physical activity. Most resources describe community health programs that have successfully changed physical activity health behaviors and health outcomes.

Create an Action Plan

The nurse and program team determine program goals and objectives and search for potential evidence-based strategies to meet objectives before creating the program **action plan**. An action plan provides concrete steps to achieve program goals and objectives. A written action plan improves efficiency and accountability, helps the team ensure all program details are considered, and provides credibility for program strategies. An action plan should be complete, communicating every step of the program implementation and plan for evaluation; clear; and current. The

action plan is a work in progress and may be revised as resource availability and community needs change. The team may also modify the action plan if processes and activities are not working as planned.

The action plan includes health promotion and disease prevention interventions based on assessment data, health behavioral change and health promotion theories, relevant literature, and input from community members, partners, and the target population (Fernandez et al., 2019). The team writes action steps for each program objective, including information regarding what intervention will occur, who will carry it out, when the intervention will take place and for how long, what resources are needed to carry out interventions, and what communication should occur (CDC, 2013). According to Issel and Wells (2018), the nurse and program team should choose interventions that

- are evidence-based and have been proven to reduce the identified health problem;
- are tailored to the target population, including cultural and linguistic appropriateness, learning needs, and motivation level;
- lead to improved health outcomes;
- are flexible with the ability to adjust activities to the participants' needs;
- are technologically and logistically practical;
- are of reasonable cost;
- are acceptable to participants, partners, and policymakers; and
- address community priorities.

In addition to interventions, the nurse and program team consider potential barriers to the action plan, communication strategies, and plan for evaluation, all of which are discussed in detail in [Implementation and Evaluation Considerations](#). The program team identifies potential barriers to address before implementation, such as resource availability, time involved to carry out actions, and community support (CDC, 2013). As part of the action plan, the program team plans strategies for communication. This includes what needs to be communicated and to whom, as well as accountability, method, and timing for communication (CDC, 2013). Examples of communication include program advertisement and recruitment, updates to the program team and partners, and dissemination of the program evaluation. The CDC offers a [program planning workbook \(<https://openstax.org/r/healthprotection>\)](https://openstax.org/r/healthprotection) to assist in an action plan and communication strategy development. Finally, the nurse and program team plan for the evaluation of the process and outcome objectives to determine the efficiency and effectiveness of program implementation and to improve and account for program decisions and actions.

The goal of any community health program is to motivate and empower the community to adopt healthy behaviors and reduce unhealthy ones. The nurse, throughout the process of program planning, engages the community through partnerships and coalitions to increase the efficiency and effectiveness of program interventions. Health promotion, disease prevention, and behavior change theories and models are also used to increase effectiveness in achieving program goals. The nurse and program team choose evidence-based, relevant, and current interventions to enhance opportunities for success. Finally, the process and outcomes of program planning and implementation are evaluated to determine if program revisions are needed to ensure the achievement of goals and objectives.

Chapter Summary

18.1 Theories and Models to Guide Program Planning

Theories and models of health promotion, disease prevention, and behavior change are used in the development of community health programs. Common theories include the community action model, PRECEDE-PROCEED model, PATCH model, and intervention mapping. Logic models are created as a visual representation of a community program. SDOH and population learning needs are also considered. Health promotion and disease prevention approaches, such as the HBM, transtheoretical model, and SCT, are applied to motivate and promote program participant behavior change.

18.2 Partnerships and Coalitions in Program Planning

A participatory approach plays a key role in the success of community health programs. The nurse engages members of the target population, organizations, and other interested parties by creating partnerships and coalitions. The nurse uses various strategies to identify and recruit partners, such as social networking,

Key Terms

- action plan** provides concrete steps of strategy implementation to achieve program goals and objectives
- capacity** the resources and relationships required to implement the program
- coalition** a group of people and organizations that work to address community needs and solve community problems
- community engagement** the process of working collaboratively with and through groups of people to identify the health needs of community residents and strategies to address those needs
- goals** statements that explain the purpose of a program and what the program plans to accomplish
- incentives** rewards used to motivate program participants to do something
- logic model** a tool to visually present the relationships among resources that are used to implement a program, the activities planned, and the intended results of the program
- objectives** statements of specific actions or behaviors that lead to the accomplishment of program goals
- outcome objectives** the stated intended results of

community mapping, and partner analysis. Established program partners develop a shared vision, values, and capacity for the community health program. The team also considers ethical standards and potential ethical issues throughout program planning, implementation, and evaluation.

18.3 Developing Program Goals and Measurable Objectives to Demonstrate Outcomes

The final steps of program planning involve the creation of program goals, objectives, outcomes, and an action plan. Goals explain the program's overarching purpose, and objectives describe specific actions that will lead to the achievement of program goals. Well-written objectives are SMART, include both process and outcomes, and have short-term, intermediate, and long-term time frames for achievement. The action plan is a step-by-step strategy for the implementation of evidence-based intervention. Healthy People 2030 can be used to search for relevant, current, and evidence-based interventions.

activities or a program, focusing on changes in knowledge, skills, and attitudes of participants and community members or changes in policies, systems, or environments

process objectives direct activities to be completed in a specific time frame and describe participants, interactions, and activities

program an organized public health action or set of related activities undertaken to achieve an intended outcome

program planning selecting and implementing a set of activities to achieve desired health outcomes; serves as a blueprint for the coordination of resources to carry out planned activities

social networks linkages among individuals, groups, and organizations that arise out of geographical location, work relationships, school relationships, or recreational activities

team dynamics relationships, interactions, attitudes, and behaviors that arise when a group of individuals work together

values core principles and beliefs that direct a team

vision a statement that articulates the desired goals that a planning team aspires to achieve

Review Questions

1. Which intervention would the nurse include in a plan of care for a client in the preparation stage of the transtheoretical model?
 - a. Provide education on the benefits of weight loss
 - b. Assist in development of realistic goals for weight loss
 - c. Assist in identification of triggers for return to a sedentary lifestyle
 - d. Provide positive reinforcement after starting an exercise program
2. A nurse using the intervention mapping framework to plan a community health program has selected activities to meet program goals. What is the next step in the framework?
 - a. Draft program messages and materials
 - b. Conduct a community assessment
 - c. Establish community partnerships
 - d. Develop evaluation methods
3. Which question might the nurse answer to determine if the ethical standard of proportionality will be upheld during a community health program?
 - a. Do the program benefits outweigh the potential risks?
 - b. Do the program planners provide rationale for program choices?
 - c. Does the program decrease health inequities identified in the community?
 - d. Has the target population been involved in the program planning process?
4. Which of the following is a physical resource that the nurse would identify during community asset mapping?
 - a. Staff training and experience with program planning
 - b. Educational resources in several languages
 - c. A large conference room to hold meetings
 - d. Advocacy for political change to advance health outcomes
5. Which of the following is an example of a program objective written using the SMART approach?
 - a. Colon cancer screening will increase in the community.
 - b. Reported alcohol use by county youth will decrease from five percent to four percent by December 31, 2025.
 - c. By next year, more county residents will meet physical activity recommendations.
 - d. County adult obesity rates will decrease from 60 percent to 30 percent within the next 2 months.
6. A nurse creating a coalition for healthy living completes which activity during step 3, develop partnership agreements, of the eight-step plan to engage potential partners and mobilize community partnerships?
 - a. Identify potential partners
 - b. Determine responsibilities of each partner
 - c. Develop a shared purpose for the coalition
 - d. Communicate evaluation results to partners
7. Which statement is an example of a process objective a nurse would develop for a nutrition program?
 - a. By December 2024, participants will state a positive view of the nutrition program.
 - b. By June 2025, participants will increase daily fruit and vegetable intake.
 - c. In 6 months, 60 percent of county residents will meet daily fiber requirements.
 - d. By January 2025, six “eating healthy on a budget” classes will be offered.
8. Which process will the nurse involved in a research study utilize to protect participant autonomy and informed consent?
 - a. Obtaining Institutional Review Board approval
 - b. Following Health Insurance Portability and Accountability Act (HIPAA) guidelines

- c. Ensuring Family Educational Rights and Privacy Act (FERPA) protections
 - d. Adhering to Affordable Care Act (ACA) regulations
- 9.** Which factor would the nurse assess to determine the social determinants of health in a community?
- a. Age of community members
 - b. Physical activity
 - c. Nutrition
 - d. Level of education
- 10.** Which belief by an individual indicates to the nurse that the individual is ready for a health change?
- a. They believe they are susceptible to a health problem.
 - b. They believe the health problem is not serious.
 - c. They believe taking action will have no effect on the health problem.
 - d. They lack confidence in their ability to make a change.

CHAPTER 19

Planning Community Health Education

FIGURE 19.1 Nurses are integral to the public health team, educating clients at multiple levels. The nurse in this photo is teaching pregnant clients techniques for breastfeeding their infants. (credit: modification of work “Prenatal Breastfeeding” by Deidre Smith/U.S. Navy/Flickr, Public Domain)

CHAPTER OUTLINE

- 19.1 Principles of Planning in Health Education Practice
 - 19.2 Developing a Health Education Plan
 - 19.3 Steps Involved in Planning Health Education Activities
-

INTRODUCTION Becky, a public health nurse, identifies increasing rates of sudden infant death syndrome (SIDS) across the country within various populations. Upon review of local community assessment data, Becky notes that community SIDS rates match the national average, which both have increased over the past 5 years. Concerned, Becky begins planning for a SIDS prevention education program. She identifies interested partners and forms an interdisciplinary team to assist in planning. The team outlines available resources and decides on an education plan and interventions to implement within the community. Part of this plan is to partner with community advocacy groups to evaluate infant sleep conditions and provide community education using multiple methods. The program will initially run for 3 months, followed by an evaluation of the plan and its execution to determine its effectiveness.

Planning community health education effectively is a multifaceted process encompassing various health disciplines. Becky seeks the support of various community partners to help ensure the SIDS prevention education program’s success. Public health nurses are crucial in this process as they have expertise in client care and advocating for clients. This chapter will discuss principles of planning in health education practice, developing a health education plan, and steps involved in planning health education activities.

19.1 Principles of Planning in Health Education Practice

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 19.1.1 Identify the importance of planning in health education.
- 19.1.2 Discuss the principles of planning in health education practice.
- 19.1.3 Describe the significance of conducting a needs assessment to the planning process.

Community health education is the process of providing information regarding optimal health and wellness at the community level (American Public Health Association [APHA], 2023). This process involves surveying a community to determine health issues and trends in order to find solutions. Community health educators may work with local schools, government agencies, health departments, and other community agencies to identify education needs. Health education programs inform individuals, families, groups, and communities on topics such as substance misuse, chronic disease prevention and treatment, nutrition, exercise, mental health, and maternal/fetal health. Community education provides accurate information to community members to equip them to make healthy lifestyle choices. Education also improves health literacy, making it easier for clients to navigate the health care system. While education may not be the only factor influencing knowledge, attitude, and behavior, it is instrumental in assisting the learner in making changes toward a healthier lifestyle. Health education may involve disseminating foundational information and/or helping clients implement it in specific circumstances. Behavior change is a multifactorial process for clients that begins with a desire or reason to change and education on what to change and how to change. This allows clients to develop and take actionable steps to meet their needs.

Health education programs may look different depending on the community as they should be adapted to meet the needs of each community's learners. The overall goals of these education programs should be to protect and promote clients' health at the individual, community, and population levels. Some examples of health education programs include:

- Tobacco control programs
 - Example: [smokefree.gov \(https://openstax.org/r/smokefree\)](https://openstax.org/r/smokefree)
- Sudden infant death syndrome (SIDS) education
 - Example: [Safe to Sleep \(https://openstax.org/r/safetosleep\)](https://openstax.org/r/safetosleep)
- Obesity
 - Example: [We Can! \(https://openstax.org/r/nhlbi\)](https://openstax.org/r/nhlbi)
 - Example: [Aim for a Healthy Weight \(https://openstax.org/r/nhlbilose\)](https://openstax.org/r/nhlbilose)
- Suicide prevention curriculum
 - Example: [Comprehensive Suicide Prevention Program \(https://openstax.org/r/suicide\)](https://openstax.org/r/suicide)

Importance of Community Health Education

Educational attainment can lead to better jobs, higher incomes, stress reduction, and improved social and psychological skills (Virginia Commonwealth University, 2022). The relationship between education and health is a symbiotic one; education has been shown to improve overall health, and poor health has been shown to have a negative impact on educational attainment. [Figure 19.2](#) demonstrates the links between education, health, and contextual factors for overall well-being. Education increases awareness of health issues, provides methods to prevent health complications by identifying health concerns early, and enables clients to seek treatment as needed. Prevention of disease and disability leads to healthier lifestyles and reduces health care costs.

Community health education places power in the hands of the client to make informed decisions regarding their health and well-being, leading to longer, healthier lives. In the long run, educational interventions should improve health outcomes and minimize long-term disability. Education improves client autonomy by providing skills and knowledge clients can use to make better-informed health and lifestyle decisions. It allows clients to assume personal responsibility for their health. For example, metabolic screenings can help clients identify abnormal values in their lipids early. This early identification, coupled with lifestyle and dietary education in the community, can give these clients the necessary tools to enhance their diet and activity level to improve health outcomes and minimize long-term complications.

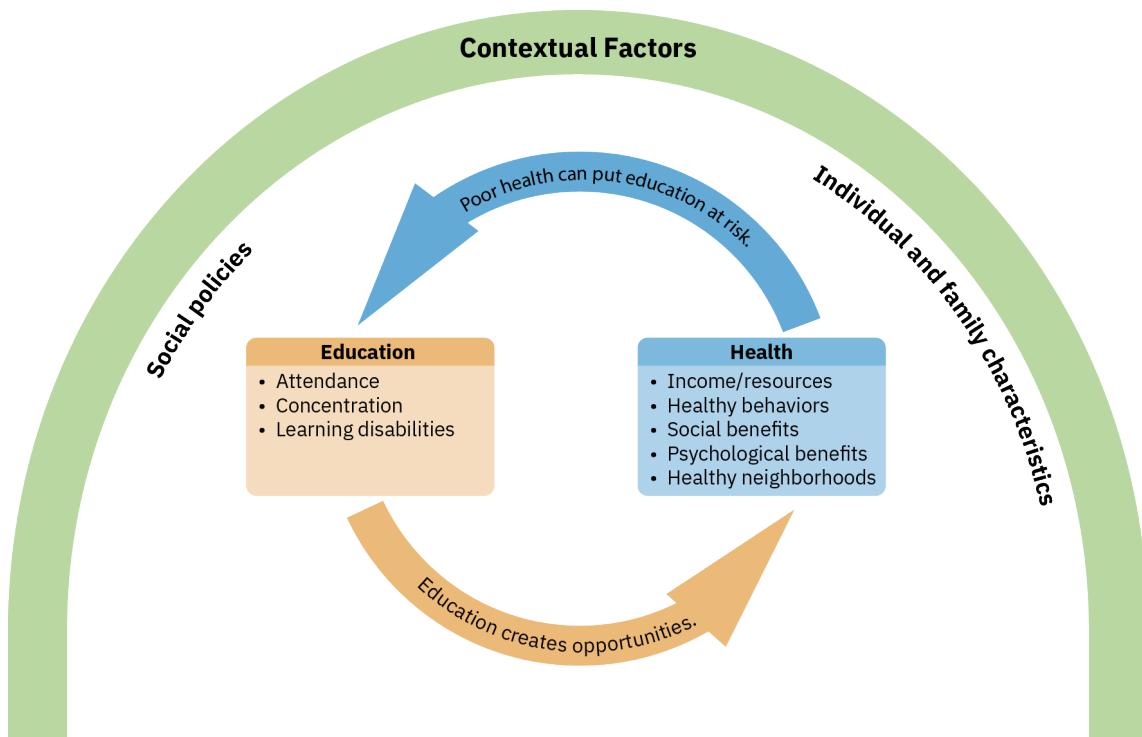

FIGURE 19.2 There is a direct link between education and health outcomes. Contextual factors must also be considered in both education and health. (See Virginia Commonwealth University, 2022; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

THEORY IN ACTION

Why Education Matters to Health

[Access multimedia content \(<https://openstax.org/books/population-health/pages/19-1-principles-of-planning-in-health-education-practice>\)](https://openstax.org/books/population-health/pages/19-1-principles-of-planning-in-health-education-practice)

This Robert Wood Johnson Foundation video discusses the importance of education to health care outcomes.

Watch the video, and then respond to the following questions.

1. How does socioeconomic status impact education levels and access to education?
2. Discuss the multiple factors involved in children feeling safe. How do these factors influence the ability to learn?

Community health nurses play a foundational role as educators. The [10 Essential Public Health Services \(<https://openstax.org/r/publichealthgateway>\)](https://openstax.org/r/publichealthgateway) and Healthy People 2030 objectives clarify the community nurse's role as an educator. An essential role of public health nurses is to "communicate effectively to inform and educate people about health, factors that influence it, and how to improve it" (Centers for Disease Control and Prevention [CDC], 2023a, para 3). Therefore, the community health nurse provides education with every intervention and across all levels of prevention. For example, education at the primary level of prevention includes health promotion, such as vaccination, exercise, and diet. Education at the secondary level of prevention includes information on health screening results, early diagnosis, and early treatment of disease. Education at the tertiary level of prevention provides ways to prevent further disability and improve lifestyle following diagnosis of a disease or disability. Nurses educate clients about specific disease states and problems and provide information about available health care services. Community health nurses also teach about behaviors to promote overall wellness and prevent illness.

HEALTHY PEOPLE 2030

Health Education

Several objectives of Healthy People 2030 focus on increasing health education of individuals, groups, and

communities. Examples include the following:

- [EBCP-01: Increase the proportion of adolescents who participate in daily school physical education](https://openstax.org/r/schools) (<https://openstax.org/r/schools>)
- [FP-08: Increase the proportion of adolescents who get formal sex education before age 18 years](https://openstax.org/r/family) (<https://openstax.org/r/family>)
- [D-06: Increase the proportion of people with diabetes who get formal diabetes education](https://openstax.org/r/diabetes) (<https://openstax.org/r/diabetes>)
- [EMC-D03: Increase the proportion of children who participate in high-quality early childhood programs](https://openstax.org/r/children) (<https://openstax.org/r/children>)
- [AH-R06: Increase the proportion of schools requiring students to take at least 2 health education courses from grades 6–12](https://openstax.org/r/schoolsrequiring) (<https://openstax.org/r/schoolsrequiring>)

Due to the importance of health education, the planning and implementation of education should not be done haphazardly. The process requires significant forethought. The planning process both identifies and prioritizes health problems. During educational planning, nurses identify available resources and then allocate them efficiently. Ultimately, detailed planning can help health care providers develop the most successful methods to educate community members and prevent duplication of activities already being used.

Principles of Planning

Planning a community health education program requires significant preparation. First and foremost, it is crucial to understand the community's health care and educational needs. This can be achieved through a **community health needs assessment** (CHNA), which identifies a community's strengths, resources, and current needs. CHNAs establish a foundation for planning and are discussed in detail in [Assessment, Analysis, and Diagnosis](#). Additionally, nurses must consider the potential learners' interests and motivations. Programs that do not appeal to these interests will have limited client participation. For example, if the community health nurse identifies increasing rates of sexually transmitted infections (STIs) and wishes to initiate a community health education plan to reduce these rates but the community members do not believe this is a pressing concern, the nurse will not receive support and the initiative will likely be unsuccessful. The initiative may fail if community members do not participate in the health education program or funders and government officials do not support the plan.

Additionally, creating health education activities with the people involved in their implementation will likely increase participation and acceptance. For example, if those teaching the content are involved in planning, the intervention will likely be more successful. Examples of health education activities may include classes, courses, workshops, seminars, conversations, media advertisements, and/or webinars. These activities may use multiple forms of information dissemination, such as websites, videos, books, pictures, and/or software programs (Rural Health Information Hub, 2023). While creating health education activities, nurses should consider available community resources. Examples of resources are time, personnel, training, and financial organization. The planned educational activity should be achievable using these resources.

The nurse and health care team must remember to be flexible. While they should complete essential planning before program implementation, modifying plans along the way may be necessary to better serve the community. These alterations could be due to a change in resources or a change in problems if a new, more urgent problem develops. Health care providers must be trained and supported to effectively deliver education programs and maintain program implementation consistency. A successful health education program should be holistic, intersectional, participative, and equitable (World Health Organization [WHO], 2023). Health education programs can be guided by theoretical frameworks or models. Theoretical frameworks and models that can be used in program planning are discussed in [Planning Health Promotion and Disease Prevention Interventions](#).

19.2 Developing a Health Education Plan

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 19.2.1 Identify theories and/or models, methodologies, and health literacy to guide the development of an education plan.
- 19.2.2 Prioritize the experiences and perspectives of the individual, family, community, system, or population when planning health education interventions.
- 19.2.3 Explain the relevance of utilizing evidence-based teaching materials, considering health literacy, vision, hearing, and cultural sensitivity.

When planning education programs, the nurse considers learning theories, the intended learner's experiences and perspectives, and available evidence-based resources. To employ learner-centered education models, the educator should consider the range of learning theories and use strategies that best satisfy intended learners' different learning styles. Planning programs with the intended learners' experiences and perspectives in mind allows the nurse to provide education to the right people using the right methods at the right time. Using evidence-based resources ensures the most positive learning outcomes and may save resources and time during program development, eliminating the need to develop new content and materials. Nurses must consider Maslow's hierarchy of needs while assessing learner needs and making health education plans ([Figure 19.3](#)).

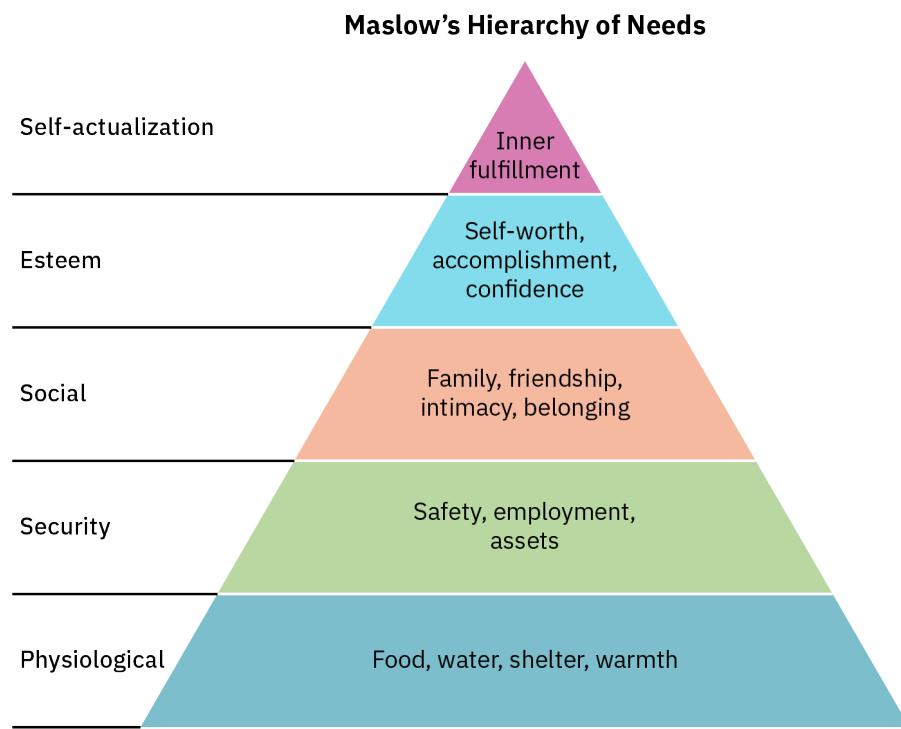

FIGURE 19.3 Maslow's hierarchy of needs begins with the foundation of the most basic human needs. It moves up to higher levels of achievement and self-actualization. While executing humanism in health care, these needs must be assessed and met to appropriately implement education to the community. (credit: modification of work from *Psychology*, 2e; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Learning Theories

Learning theories provide a foundation for education programs. They help nurses understand how people learn, and nurses can then apply this understanding when developing health education plans for the community. [Table 19.1](#) presents widely accepted learning theories for developing a health education plan.

Learning Theory	Description	Application
Behaviorism	<ul style="list-style-type: none"> • Behavior is learned from the environment and can be conditioned. Conditioned behaviors occur more frequently with positive consequences or less frequently with negative consequences. • Behaviorism focuses on observable behavior. • Learning is new behavior, not new knowledge. All behaviors can be unlearned and replaced by new behaviors. • Positive consequences (rewards) promote behavior. Negative consequences (punishment) discourage behavior. 	<ul style="list-style-type: none"> • Provide positive consequences for desired behaviors, such as offering praise or positive verbal reinforcement, when a client demonstrates the correct method of self-insulin administration. • Assist the learner in identifying possible positive self-reinforcement or negative consequences to lead to behavior change. • Develop a contract for behavior change.
Social Cognitive Learning Theory	<ul style="list-style-type: none"> • Learning occurs in social contexts with the interaction of the person, environment, and behavior. • Experienced or witnessed behavior can lead to cognitive, affective, and behavioral changes. • External and internal social reinforcement lead to learning. • Past experiences, reinforcement, expectations, ability, modeling, and self-efficacy influence learning and behavior. 	<ul style="list-style-type: none"> • Assess past experiences and ability. • Reinforce desired behaviors. • Model desired behaviors. • Enhance personal (internal) factors, such as self-efficacy. • Use media to promote healthy behaviors and decrease unhealthy behaviors.
Constructivism	<ul style="list-style-type: none"> • Learners actively use experiences and reflection to build upon preexisting knowledge rather than passively taking in information. • Knowledge acquisition occurs through interactions with others and with information. • Educators facilitate learning but do not lead it; learners take ownership of learning. 	<ul style="list-style-type: none"> • Assess for current knowledge and build on what is already known. • Engage learners through discussion and activities. • Provide experiences to construct knowledge. • Allow time for reflection.

TABLE 19.1 Learning Theories to Develop Community Health Education Programming

Learning Theory	Description	Application
Humanism	<ul style="list-style-type: none"> • The desire to learn is innate, with the goal of self-actualization. • Learners must have lower-level or basic needs met prior to learning. • The educator provides minimal structure; instead, the learner has the responsibility to learn as desired. 	<ul style="list-style-type: none"> • Assess for educational needs/desires. • Provide resources for the learner to create personal education. • Ensure basic needs, such as food, water, shelter, warmth, and security, are met to support the learners' accomplishment of higher-level needs.
Adult Learning Theory	<p>Adults are motivated to learn when they:</p> <ul style="list-style-type: none"> • believe they need to know something, • can fit new information into previous and current life experiences, • value the person providing the information, and • believe that they can make changes implied by the information. 	<ul style="list-style-type: none"> • Assess for educational needs/desires. • Assess for current knowledge to build upon what is already known. • Apply new information to past and current life experiences. • Ensure the educator is respected and knowledgeable. • Assess self-efficacy and motivation.
Connectivism	<ul style="list-style-type: none"> • Learning occurs when making connections between internal (previous knowledge and qualities) and external sources (technology, people, and other resources) with the aim of having accurate and current information. • Decision-making is a learning process because what we know changes. • Information from multiple sources may lead to a diverse view of problems and, thus, unique solutions (D'souza et al., 2021). 	<ul style="list-style-type: none"> • Provide opportunities for learners to share perspectives and opinions. • Create activities that involve collaboration. • Use social media, the internet, blogs, and online forums to increase connectivity and conversation.

TABLE 19.1 Learning Theories to Develop Community Health Education Programming

One or more learning theories may guide the development of the health education program. The nurse should choose learning theories aligning with the health problem, targeted learner, and anticipated learner needs. For example, if the educational program will be provided in-person to a group of adult learners, the nurse may choose to follow adult learning theory and social cognitive theory. If the educational program is provided on a large scale to the entire community, the nurse may use connectivism as a guide.

THEORY IN ACTION

Connectivism

[Access multimedia content \(<https://openstax.org/books/population-health/pages/19-2-developing-a-health-education-plan>\)](https://openstax.org/books/population-health/pages/19-2-developing-a-health-education-plan)

This video discusses connectivism and explores how to use this learning theory in multiple venues, including community health education programs.

Watch the video, and then respond to the following questions.

1. What are potential barriers to using this learning theory, and how can nurses help learners overcome them?
2. How can nurses use connectivism in community health education programs?

Factors to Consider When Planning for Education

Other factors to consider when planning for health education programs include learner needs, experiences, and perspectives; whether the client will be individuals, families, groups, or the community; the goals and objectives of the program; the availability of tests, evidence-based educational materials, and curriculum; and the availability of resources.

Learner Experiences, Perspectives, and Needs

While identifying the client, it is important for the nurse to examine the learning considerations for the intended target population. Nurses should consider many population characteristics when developing educational materials and deciding on delivery methods. Developmental level, for example, may dictate how the population should receive the information. Young children learn best when the information is delivered in small chunks with supporting visuals and audio. As children move into school age, they are often able to obtain and comprehend more information with increased complexity. At this time, the family is the largest influence on a child's behavior, so the family could be included in the educational program. As clients enter adolescence, they respond best when treated with respect and provided the information directly. Peer influence is much stronger at this stage as an adolescent's autonomy increases (National Institute of Mental Health, 2023). Education should move from generalized to more individualized components related to their specific stage of life, so nurses may incorporate peer activities into the learning process for this population.

The general adult population seeks learning that is convenient and specific to their needs. Depending on their age and background, some adults may prefer printed forms of education versus solely electronic, while some may prefer the speed and convenience of electronic information. In today's world, the use of and reliance on technology is ever increasing. While the increased use of technology has many advantages, specific populations may lack access, understanding, or a desire to use these learning methods. Additionally, adult learners appreciate pulling from their previous experiences and life circumstances. The more teaching can utilize adults' past experiences, the more effective it will be. Some older adults may require additional time to become comfortable using technology for communication and information sharing (Ahmad et al., 2022). It is essential to remember that age does not directly correlate to developmental level. Development is multifactorial, so nurses should base education on how clients obtain, comprehend, and use information instead of their biological age.

Health literacy is another crucial factor when creating community education plans and resources. As discussed in detail in [Assessment, Analysis, and Diagnosis](#), personal health literacy is the degree to which individuals can find, understand, and use information and services to inform health-related decisions and actions for themselves and others. Assessing population health literacy begins with evaluating how well clients use everyday written materials to accomplish common tasks and progresses to assessing more conceptual ideas of mathematical and problem-solving concepts. This evaluation is often completed via a survey, and these surveys have been adapted over time to improve concepts and match the language of those being evaluated. Community health and public health nurses can view statistics within the United States to gain a broad view of national health literacy levels and can furthermore complete evaluations within a selected community or population to determine local literacy levels. According to the U.S. Department of Health and Human Services, in 2019, 12 percent of Americans measured proficient in health literacy from the National Assessment of Adult Literacy (NAAL). Survey data show a marked gap

between the portion of the population who are highly health literate and those who are well below average for health literacy levels. This gap creates additional complications when planning for health education that meets clients at their current health literacy level or fills gaps in literacy levels to improve understanding.

While developing educational materials, the nurse should consider the target population's general and health literacy and tailor the materials accordingly. Nurses must be able to adjust their education styles to match the health literacy of the populations in which they work. This often means creating educational materials at the lowest level of literacy identified within the community to ensure all clients can understand and apply the information. Additionally, nurses should present education in multiple forms to capture the audience and convey meaningful information they can utilize. Thus, not only should the materials used to evaluate health literacy be considered, but so should the rigor and skills of the educator who is providing the information. Nurses should consider sociocultural factors regarding access to information and how it is disseminated within a community. Furthermore, any practices and policies used within the population in question should be considered to produce effective communication. If the norm of a particular community is that clients do not read or use written information to gain knowledge, then providing only written material will not best serve this community. Finally, with the growing diversity of the general population, preferred language must be considered for all forms of education and educational materials. The nurse should consider the preferred language for each client and the extent to which the client is fluent in this language. For example, some clients may be able to speak English but may not be able to read in this language, and vice versa.

THE ROOTS OF HEALTH INEQUITIES

Health Literacy and Health Inequities Are Closely Connected

To act on health education information, clients must be able to access and understand it. Effective communication is integral to the overall health education process as it delivers information and can modify beliefs and attitudes, provide encouragement, and encourage thinking. In communication for health education, nurses should keep health equity concerns in mind. When equity principles guide communication, clients are more likely to act on what they learn as the information is more likely to meet the needs of the client(s), incorporating their linguistic, environmental, cultural, and historical needs. Due to the importance of these concepts, the CDC created "Health Equity Guiding Principles for Inclusive Communication."

These principles can be reviewed on the CDC's website here:

[Inclusive Communication Principles \(<https://openstax.org/r/healthcommunication>\)](https://openstax.org/r/healthcommunication)

Review this information, and then respond to the following questions.

1. What are two key principles nurses can use in communication and health education programs?
2. Explain what it means to use a health equity lens and provide two examples of how nurses can utilize this strategy in health education.

(See Office of Disease Prevention and Health Promotion, 2021.)

The nurse should evaluate the client's abilities or limitations and health literacy levels. For example, if clients have any hearing or vision deficits, this must be considered in the creation and distribution of educational information.

Understanding the specific culture of the community and those within the community is imperative, as many cultures view health and illness differently. Thus, communities will have different ideas of what is important. Linking back to the recipe for a successful education plan, buy-in from interested parties and participants is crucial for overall program success.

Cultural sensitivity entails an awareness of similarities and differences between cultures while not placing value on or ranking these similarities and differences. Nurses can take steps to apply cultural sensitivity when planning health education practices. The nurse must begin with awareness of different cultures. Next, the nurse can learn about their own culture and the cultures of others. When nurses show openness to and interest in a client's background and culture, listening and allowing the client to express their views, they can build trust and rapport with clients from other cultures. This may require bridging language barriers to educate clients about medical practices and options. Nurses should demonstrate **active listening** to provide a safe and effective space. Active

listening involves preparing to hear what the other person is saying, receiving the sent message, and responding thoughtfully. These steps can help health care providers gain an appreciation for what education the community may need and the most effective ways to provide it. This may also help the nurse to determine which methods would impede learning. Unit 5, Culturally Congruent Care, discusses these topics in greater detail.

CONVERSATIONS ABOUT CULTURE

Effective Communication and Health Equity

[Access multimedia content \(<https://openstax.org/books/population-health/pages/19-2-developing-a-health-education-plan>\)](https://openstax.org/books/population-health/pages/19-2-developing-a-health-education-plan)

This video from the Health Resources Services Administration (HRSA) describes how effective health care communication policies and practices, including the health literacy of providers such as nurses, help improve the quality of services for culturally and linguistically diverse populations.

Watch the video, and then respond to the following questions.

1. What are the three factors in health care communication, and how do these impact educational strategies nurses use?
2. Identify how a nurse can demonstrate culturally competent care by considering specific factors that impact health literacy while disseminating a health education plan.

Individual, Family, Group, and Community as Client

Client education occurs at individual, family, group, or community levels. The nurse must define at which client level education will occur because the level can alter the planning for and implementation of health education interventions. For example, nurses providing education for an individual client establish a more personal relationship with a single individual and cater only to their needs, wants, and learning styles. Individual health screenings and one-on-one education are examples of education at the individual level. Education at the individual level includes the person experiencing the problem or condition and can provide subjective information from their specific point of view. For example, the community health nurse may provide education to individuals on how to take blood pressure, healthy nutrition, and weight loss during a clinic visit for clients at risk for hypertension.

CLIENT TEACHING GUIDELINES

Individual-Level Health Education

The nurse teaches a client how to check their blood pressure at home in order to get a better long-term view of the client's blood pressure readings over time. The educational materials use evidence-based resources and instruct the individual client to do the following:

- Try to perform the blood pressure reading around the same time each day.
- Do not eat or drink anything 30 minutes before taking the blood pressure.
- Empty your bladder before obtaining the reading.
- Sit in a chair with your back supported and both feet flat on the ground for at least 5 minutes before obtaining your blood pressure.
- Make sure you have the right size blood pressure cuff. This cuff should fit snugly on your upper arm or wrist, but not too tight.
- Place the blood pressure cuff only on bare skin, not over clothing.
- Do not talk or move during the reading.
- Keep track of each reading in a journal, including day, time, and blood pressure reading.

(See CDC, 2023b.)

As noted, education may also occur at the family level. Everyone defines family differently. Some people define family as blood relatives, while others consider those closest to them, such as friends or neighbors, their family. Additionally, there are many ways in which a family is formed, all of which should be respected and acknowledged.

One example of respecting this idea is for nurses to clarify family roles before assuming what they are. Not all adults with a child are the child's parents, so clarifying these roles before engaging the family will build trust and respect. Generally, *caregiver* is a more encompassing term when addressing those helping provide care for a client. This concept is discussed further in [Caring for Families](#).

As the nurse provides education to multiple people at a time, the scope of the intervention and teaching strategies can change dramatically. Education plans and strategies at the group and community levels are not personalized for individuals but rather for identified health problems of populations at risk and of the community as a whole. An example of a community program that includes family education is the [Help Me Grow Program](#) (<https://openstax.org/r/odhohio>). In this program, the nurse determines family concerns and needs during home visits and provides education and support to new parents and caregivers. Educational topics include healthy pregnancy, safe sleep practices, breastfeeding, newborn and child growth and development, nutrition, immunizations, and safety.

Education may occur at the group level to community members who share a common health need or problem. In this circumstance, the nurse provides education to a group of community members at the same time in the same place. For example, a nurse may provide a breastfeeding class to 10 pregnant clients, as shown in [Figure 19.1](#). Teaching at the group level allows the nurse to educate several individuals simultaneously, increasing program impact and reducing needed resources. Additionally, group members share experiences and perspectives, leading to an enhanced learning environment. The nurse providing education at the group level must have knowledge and experience in group processes.

EDUCATING GROUPS

Steps to follow when educating groups of people include the following:

- Brainstorm educational topics and plan for the group
- Refine leadership skills and style
- Form the group
- Complete introductions as indicated
 - Educator
 - Members
 - Subgroups
- Create an environment of respect for group
 - Set group norms for communication
 - Do not interrupt one another
 - Respect different perspectives and learning styles
 - Support one another and help when possible
- Set expectations for the group and for education completion
 - Discuss learning wants and needs
 - Set expectations to meet outcomes
 - Solicit fears or concerns and discuss as needed
- Anticipate and mitigate possible challenges
 - Dominating or intimidating group members
 - Education not going as planned
 - Technology issues
 - Lack of participation
 - Conflict
- Assess group learning and reflect for changes next time

Finally, education can occur at the community level. In this instance, education is usually large-scale and includes the use of media, such as flyers, billboards, newspapers, television, radio, or social media platforms to disseminate educational materials. Often, this takes the form of **public service announcements** (PSA) or **national campaigns** to reach a wider audience. A PSA is a message, video, or broadcast authorized by a government agency or nonprofit

organization to provide information about an issue at the public level. A national campaign is a series of planned activities or marketing offerings to communicate information to the public on a national scale.

PUBLIC SERVICE ANNOUNCEMENT: ALLYSON FELIX

[Access multimedia content \(<https://openstax.org/books/population-health/pages/19-2-developing-a-health-education-plan>\)](https://openstax.org/books/population-health/pages/19-2-developing-a-health-education-plan)

A PSA can disseminate information to multiple people simultaneously. This CDC video and [web page](https://openstax.org/r/hearer) (<https://openstax.org/r/hearer>) feature its HEAR HER™ campaign to educate individuals on the risks of pregnancy-related complications.

Watch the video and visit the website, and then respond to the following questions.

1. What population is this PSA targeting?
2. Do you think this PSA featuring Allyson Felix is effective? Why or why not?
3. When would a PSA be an effective tool in health education? When would it be less effective?
4. Brainstorm two topics that would best be disseminated via a PSA.

Goals and Objectives of the Educational Program

The nurse identifies the goal of the educational program during the first stages of planning following a needs assessment. Goals are broad, long-term statements about the educational program's purpose and what it will accomplish. For example, a goal for an educational program on breastfeeding is "mothers receiving education will breastfeed their infant for the first 6 months following birth." Goals stem from prioritizing needs identified during the community health needs assessment and learner assessment, if available, focusing on health promotion and illness prevention. The nurse considers learning needs, motivation for learning, and available resources to conduct the educational program.

Next, the nurse identifies the educational program's objectives. Objectives are specific, short-term statements demonstrating progress toward the goal. Written in SMART format, they signify a change in learners' knowledge, skill, or attitude. For example, an educational program on breastfeeding might use these SMART objectives:

- Knowledge: At the end of the class, mothers will state three benefits of breastfeeding.
- Skill: At the end of the class, mothers will demonstrate three methods to effectively position the infant for breastfeeding.
- Attitude: At the end of the class, mothers will state increased motivation to breastfeed their newborn.

[Planning Health Promotion and Disease Prevention Interventions](#) provides detailed information on writing goals and objectives.

Finally, the nurse uses the identified goals and objectives to plan curriculum, materials, and other resources to help learners accomplish them.

Available Evidence-Based Materials and Curriculum

The nurse searches for educational curricula, materials, and other resources that have been proven effective in achieving the identified educational program goals and objectives. This reduces the planning time and resources it would take to create new curriculum and materials, increases the likelihood that the program will succeed, and provides supporting evidence for curriculum and material decisions. Evidence-based practice and evidence-based decision-making are discussed in detail in [Evidence-Based Decision-Making](#).

Evidence-based health education programs are found by searching published journals, national and state websites dedicated to public health, and local organizations, schools, and agencies providing health services. Additionally, the nurse may contact experts who work in public health or education and experts on the health topic. Healthy People 2030 is a good starting point because it includes evidence-based resources and programs for national health topics and objectives. The CDC is also a good resource. For example, it describes evidence-based [community health programs](#) (<https://openstax.org/r/ncccdphpdch>) focusing on chronic diseases such as stroke, heart disease, and obesity. Finally, the National Institutes of Health ([NIH](https://openstax.org/r/preventionnih) (<https://openstax.org/r/preventionnih>)) provides an updated list of links to current, evidence-based programs and resources. Ultimately, education tactics should utilize the best

available research and noted experience from experts in that field.

19.3 Steps Involved in Planning Health Education Activities

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 19.3.1 Explain the six steps of planning health education interventions.
- 19.3.2 Develop a health education plan, taking into consideration the literacy level of the population served.
- 19.3.3 Describe strategies to enhance communication with the team while planning community interventions.

Planning and implementing health education activities is a team effort, relying on multiple members for ultimate success. A foundational aspect of teamwork is effective communication. Nurses leading a team must be aware of methods to facilitate communication, possible barriers to communication, and how to overcome these barriers.

From the foundation of the health education plan, the nurse and other team members can then formulate health education activities. Similar to developing the health education plan, developing health education activities requires an evaluation of the client's needs, available community resources, team composition, and skill set of each team member. The six integral steps of planning a health education intervention or program include:

- Identifying learning needs
- Establishing goals and objectives
- Selecting appropriate education methods
- Designing and implementing the educational program
- Evaluating the educational process and program's effects
- Determining if revisions to the plan are needed

Steps of Planning Health Education Interventions

[Table 19.2](#) describes the steps the nurse and team take when planning health education interventions; steps 1–2, identifying learning needs and establishing goals and objectives, were discussed previously.

Step	Activities
1. Identify learning needs	<ul style="list-style-type: none"> • Complete a community health needs assessment and prioritize health problems and educational needs • Complete a learner assessment that includes motivation, abilities, health literacy, culture, and other learner needs
2. Establish goals and objectives	<ul style="list-style-type: none"> • Finalize the goals of the educational program • Finalize SMART objectives
3. Select appropriate education methods	<ul style="list-style-type: none"> • Select learning theory • Determine teaching strategies and learning format • Examine and reduce possible educational issues
4. Design and implement educational program	<ul style="list-style-type: none"> • Finalize curriculum, materials, and resources • Deliver as planned
5. Evaluate the educational process and effects of the program	<ul style="list-style-type: none"> • Determine the extent to which learners met program objectives • Evaluate educators' perceptions regarding the educational process
6. Determine if revisions to the plan are needed	<ul style="list-style-type: none"> • Revise educational methods to improve outcomes • Revise educational methods to improve delivery and process

TABLE 19.2 Steps of Planning Health Education Interventions

Once the team has completed step 2 by establishing goals and objectives, the team identifies a foundational

learning theory, which includes teaching strategies and overall learning format, or how the education will be delivered: in person, online, or through written materials. Additionally, the nurse and team should determine how the teaching will take place with this information. Examples of possible ways to disseminate educational information include typed documents, slide shows, audio recordings, hands-on learning, discussions, online forums, and videos. Examples of teaching strategies include simulations, demonstrations, group activities, peer-to-peer teaching, in-person or virtual lectures, or community health fairs. The team should brainstorm and prioritize ideas for multiple strategies before making any final decisions.

When assessing possible teaching methods, nurses should identify possible barriers to effective education and how to overcome them. Some barriers may be related to the educator, such as lack of knowledge or experience, limited preparation, limited teaching skills, unfamiliarity with technology, inappropriate teaching strategy, discomfort with material or format, and unremovable distractions. Barriers may also originate with the learner, such as lack of interest or motivation, learning preferences, basic needs, attention span, level of health, level of education, health literacy, age, and experience. These barriers affect teaching at all levels: individual, family, group, and community.

Moving from step 3 to step 4, after determining the learning format and teaching strategies, the nurse and team can finalize the curriculum for learning and determine the necessary resources. Choosing an inappropriate strategy or format can lead to ineffective teaching, alienation of participants, and waste of resources. This detailed step includes producing the materials and disseminating them accordingly to the necessary parties. To create culturally and linguistically appropriate learning materials, the nurse and team should refer to the previously completed assessment of the target population's learning needs.

In step 5, the team should evaluate the education plan, reviewing indicators developed earlier in the process to determine the extent to which outcomes and objectives were completed and can be completed via observation, verbal feedback, demonstration, survey, or post-implementation worksheet. This evaluation should also survey educators to determine the effectiveness of the education process. This leads to step 6, determining if the plan requires any changes and revising educational methods to improve outcomes, delivery, and the overall process.

EDUCATIONAL PRINCIPLES TO ENHANCE THE LEARNING PROCESS

An effective educator uses several strategies to engage learners and enhance learning. Use these strategies when teaching in a face-to-face format with individuals, families, and groups.

- Gain attention by reducing environmental distractions and ensuring learner comfort
- Present the learning objectives in a realistic, reachable, and applicable way
- Assess for prior learning and experiences
- Link new information to prior learning and experiences
- Present the material in a clear, organized manner from simple to complex while considering the needs and abilities of the learners
- Engage learners through activities and discussion
- Provide guidance and feedback
- Evaluate achievement of objectives

Team Communication

Due to the depth and importance of health education activities, team members must communicate effectively with one another. Interdisciplinary health care teams, or teams comprised of individuals from different disciplines, may vary in composition but often encompass nurses, physicians, pharmacists, community health workers, and other health professionals. This broad scope allows for comprehensive education, thus meeting the community's needs. At this time, medical errors are a leading cause of death in the United States (Rodziewicz et al., 2023). Many of these errors stem from poor communication, leading to limited or ineffective education. Just as team members must work together to provide care to clients, they must work together to provide education at the community level.

With communication as the foundation for a successful project and successful health care, the Agency for Healthcare Research and Quality (AHRQ) has created **TeamSTEPPS®**, "an evidence-based set of teamwork tools aimed at optimizing patient outcomes by improving communication and teamwork skills among health care

professionals” (2023, para 5). This comprehensive, evidence-based program aims to eliminate preventable medication errors related to unproductive team communication, thus improving client safety. TeamSTEPPS stands for **T**eam **S**trategies and **T**ools to **E**nhan**C**e **P**erformance and **P**atient **S**afety. This program has five key principles: team structure, communication, leadership, situation monitoring, and mutual support ([Figure 19.4](#)). These steps lay a foundation for enhanced communication and clear roles within an education plan. More effective communication leads to more effective education and better outcomes and preventative measures for the respective population.

FIGURE 19.4 The TeamSTEPPS® framework provides a guide for the components of an effective client care team. (See Agency for Healthcare Research and Quality, 2023; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

These five key principles are based on teachable–learnable skills and their interplay with the outcomes and skills of the team. According to AHRQ (2023), the key principles are:

- Team structure: the composition of the team, including multiple backgrounds and disciplines
- Communication: plan and format for how team members will share information within the group
- Leadership: structure identified and assigned according to the team structure, which clearly identifies roles and responsibilities of each team member
- Situation monitoring: actively reviewing elements of the team and project to identify team functioning and sustain awareness of any changes
- Mutual support: team members openly communicate needs and inquiries to ensure disseminated responsibility and workload

Community Partnerships

Successful community health education and health interventions rely heavily on partnerships for success. As mentioned, a successful implementation of a community health education program involves identifying community partners and obtaining their support. Members of the partnership may change based on the needs of the program. Still, no matter the project or program, population health nurses will need support of and connection to those in the community. First, nurses must form a partnership with community members. Health education plans should center around the needs and wants of those in the community. If a relationship is not formed with these members, it will be very difficult to get accurate information regarding needs and expectations for improvement. Additionally, nurses will need to link to community partners such as primary care providers, local schools, mental health care providers, childcare services, government officials, advocacy groups, and private agencies that may have a connection to the identified public health issue.

Community **coalitions** are formalized groups of various team members who actively work together toward a common goal. Within a coalition, the group serves as a catalyst for change while each member maintains their

identity and expertise as part of the team. Coalitions can raise awareness and serve entire communities as they address broad issues and utilize partners' expertise to capitalize on talent. This process pulls the power of multiple groups in order to rectify or support an issue or event. One example of using this partnership process is the formulation of drug-free community coalitions across the United States in collaboration with the CDC (CDC, 2022a). [Advocating for Population Health](#) discusses coalition building in more detail.

Communication may occur in multiple venues depending on the size and scope of community health partnerships. Nurses should make as many one-on-one connections as possible, especially when identifying community partners, to build meaningful relationships and a foundation for future correspondence. This interpersonal form of communication may not always be possible or make sense for a specific program, so the nurse may use additional forms of communication. Email is a professional and efficient way to convey a message to one or multiple individuals and track the correspondence accordingly. This can provide specific information to the group and disseminate information in a format that reviewers can evaluate and follow up on as needed. Closed-loop virtual presentations or open-loop virtual or phone meetings are another option for communication within small or large groups. Nurses should remember that many forms of communication may be needed for any given initiative. Flexibility is critical to ensuring all community partners and team members are informed.

Barriers to Communication

Just as many tools are available to facilitate communication, many communication barriers exist. **Communication barriers** are circumstances that may impede the overall outcome or block progression. One barrier may be a lack of or an ineffective leader on the health education planning and implementation team. Ineffective leadership can impede the comfort others feel in engaging and may also create a stagnant workspace. Additionally, the education plan may not succeed if leadership is inadequate along the way. Another possible barrier is goal confusion. It is difficult for a team to achieve a goal if they do not clearly understand what it is or what role they are expected to play in achieving it. Members may disengage if they do not feel they contribute to the goal or outcome. Lack of accountability and trust can be a major barrier to communication. With these factors, members do not feel ownership of the work and/or they do not feel they can trust group members. Without trust, the brainstorming and problem-solving process will be impeded because team members feel like they cannot have an open dialogue.

Additionally, physical or logistical barriers may cause communication challenges. If team members are in different physical locations and thus unable to attach body language to words spoken, this can lead to miscommunication. Also, if all communication is completed electronically, there is more room for miscommunication as tone and volume cannot be heard or understood. Other factors to consider may be time differences based on location, cultural differences, differences in backgrounds, and past experiences. Each team member will bring great value to the table, yet each will have their own preferences and philosophies for communication. There will always be potential barriers on any team, yet an effective team should work to identify these barriers or possible barriers early on so that they put measures in place to overcome them.

Barriers within the population can impede health education plans and implementation. As discussed, low health literacy can be a massive barrier to health interventions. To understand health education and thus act on it, community members must be able to learn and comprehend it. Low health literacy levels impede this significantly. Lack of interest or enthusiasm for the intervention by either the participants or education team will also pose a significant barrier to this process. Without buy-in from interested parties, there will not be emotional, financial, or political support for any change. A population's culture may also pose a barrier. For example, if there is historic mistrust of the health care profession or previous negative experiences with health care professionals, the team will need to gain the community's trust before completing any education or interventions. Factors such as socioeconomic status, transportation availability, lack of free time to engage in learning or health programs, or lack of knowledge can all impact care at an individual and population level.

Once identified, the team should work to reduce or overcome such barriers. One major step is to focus on a single message or goal. Because it is difficult for team members to work effectively and efficiently if they do not know what they are working toward, clarifying a single goal provides direction. Moreover, each team member should understand their role in achieving this goal and feel they are contributing to the planning process. Team members should also solicit feedback frequently throughout the planning and implementation process. This allows for prompt professional and constructive feedback to make adjustments accordingly. Biases and limiting beliefs should be identified early and navigated on an individual and group level to prevent these from hindering the program.

implementation and outcomes. Underscoring all of these methods, the team should demonstrate respect and understanding for one another. This may include respect for their time, expertise, and/ or perspectives. Together, the team can work to effectively communicate, mitigate barriers, and create a successful health education program.

Chapter Summary

19.1 Principles of Planning in Health Education Practice

Planning health education should be taken seriously using a multidisciplinary approach. Planning principles include completing a community health needs assessment to identify a community's strengths, resources, and needs. Planning requires consideration of the community's interests to obtain buy-in and participation. Additional factors to consider in planning should include using evidence-based teaching materials and considering the target population's health literacy, different abilities, and culture. Cultural sensitivity should be the foundation for planned interventions to ensure they meet the needs of the community in question while respecting its culture.

19.2 Developing a Health Education Plan

The next step of community health education is to develop a health education plan. Learning theories should be the foundation for this process as they provide insight into different learning methods and help nurses and the team understand how people learn and how this can be applied to developing health education plans. Nurses should consider the client's experiences, perspectives, needs, and developmental level. Socioeconomic considerations and literacy level should be evaluated to create and disseminate appropriate information in an accessible way. To create

Key Terms

active listening preparing to hear what another person is saying, receiving the sent message, and responding thoughtfully

coalitions formalized groups of various team members who actively work together toward a common goal

communication barriers circumstances that may impede the overall outcome or block progression of a plan

community health education the process of providing information regarding optimal health and wellness at the community level

community health needs assessment (CHNA) identifies strengths, resources, and current needs of a community

Review Questions

1. Which teaching strategy should the nurse use to enhance learning when teaching a community CPR program?
 - a. Use passive learning strategies
 - b. Present materials from simple to complex

a safe and meaningful environment for all participants, cultural sensitivity should underscore each of these considerations. Widely accepted learning theories include behaviorism, social cognitive learning theory, constructivism, humanism, adult learning theory, and connectivism. Defining the client is imperative in developing health education. Clients can be defined at the individual, family, community, or population level. All curricular components should be supported by evidence-based materials.

19.3 Steps Involved in Planning Health Education Activities

After identifying the community's needs and developing a health education plan, the last step in the process is planning health education activities to be implemented. Steps for planning health education interventions include identifying learning needs, establishing goals and objectives, selecting appropriate education methods, designing and implementing the educational program, evaluating the educational process and effects of the program, and determining if revisions to the plan are needed. Effective team communication is critical to successful implementation of educational activities. Teams should work to identify possible communication barriers and rectify them promptly to achieve their goals.

cultural sensitivity an awareness of similarities and differences between cultures without making value judgments about those similarities and differences

national campaigns a series of planned activities or marketing offerings intended to communicate information to the public on a national scale

public service announcement (PSA) a message, video, or broadcast authorized by a government agency or nonprofit organization to provide information about an issue to the public

TeamSTEPPS® an evidence-based set of teamwork tools aimed at optimizing client outcomes by improving communication and teamwork skills among health care professionals

- c. Assume learners have the same baseline knowledge
 - d. Choose one learning strategy to present material
- 2.** The community health nurse is performing a community health needs assessment prior to planning a nutrition program for older adults. Which factors will the nurse identify in this needs assessment?
- a. Primary language, budget, resources
 - b. Resources, strengths, land mass
 - c. Enthusiasm, primary language, current needs
 - d. Strengths, resources, current needs
- 3.** Which action should the nurse take when developing a community health education program based on adult learning theory?
- a. Assess what the learners already know about the topic
 - b. Identify positive reinforcements to reward desired behaviors
 - c. Utilize technology to increase connectivity
 - d. Allow sufficient time for participant reflection
- 4.** Members of the health education team are meeting to review the team's progress. Which factor may adversely affect team communication?
- a. Frequent brainstorming sessions
 - b. High level of team member engagement
 - c. Low feelings of trust
 - d. Team member roles being clear
- 5.** Which activity will the nurse perform during the evaluation step of a health intervention program whose objective is to teach community members about identifying and reducing cardiac risk factors?
- a. Select the learning theory to be used in the program
 - b. Identify what learners already know about cardiac risk factors
 - c. Determine if learners can identify their cardiac risk factors
 - d. Develop strategies for teaching about cardiac risk factors
- 6.** A health care team is using TeamSTEPPS® to plan and implement community health programs. Which action will the team take using this framework?
- a. Share leadership responsibilities
 - b. Distribute information as needed
 - c. Utilize an informal communication format
 - d. Employ an interdisciplinary approach
- 7.** During a community assessment, the nurse identifies a need for safe after-school space for high school students to socialize, study, and play. Which basic human need does this nurse determine needs to be met?
- a. Security
 - b. Physiological
 - c. Esteem
 - d. Self-actualization
- 8.** While planning a community health education program for older adults who want to exercise more frequently, the health education team decides to ask participants to sign a contract where they agree to complete a certain level of physical activity each week. Which learning theory is the team utilizing?
- a. Connectivism
 - b. Constructivism
 - c. Behaviorism
 - d. Humanism

- 9.** The school health nurse is planning a community health education workshop on vaping for parents and caregivers of adolescents. To increase participation in the program, the nurse will use which strategy?
- Offer the workshop during the school day
 - Require students to attend with their caregivers
 - Limit the number of attendees
 - Involve members of the Parent Teacher Association in the planning
- 10.** The nurse knows which instruction method is most effective for adolescents?
- Providing information in small segments
 - Including family members in the learning
 - Connecting material to past experiences
 - Incorporating peer activities into the learning process

CHAPTER 20

Implementation and Evaluation Considerations

FIGURE 20.1 The Five Sandoval Indian Pueblo, Inc. provides services that incorporate the tribal community's sociocultural and linguistic needs. One service includes delivery of food boxes where the client chooses what foods are included in the box. (credit: modification of work by Lance Cheung/USDA Photos/Flickr, Public Domain)

CHAPTER OUTLINE

- 20.1 Facilitators and Barriers to Program Implementation
- 20.2 Recruitment and Retention of Program Participants
- 20.3 Evaluation Strategies
- 20.4 Communication Strategies
- 20.5 Funding and Sustainability

INTRODUCTION Nurse Diego and the program team completed an assessment and analysis of community health needs and have created a community health program that aligns with those needs. Before implementing this program, Diego considers what may impact its delivery and activities, such as participant recruitment and retention and the intended target population's sociocultural and linguistic needs. Diego and the program team must also plan for the program's communication, funding, and continuation and write a systematic evaluation plan to determine if the program's goals and objectives have been achieved.

This chapter discusses facilitators and barriers to community health program implementation, specifically focusing on participant recruitment and retention, program evaluation strategies, communication strategies regarding the program and program outcomes, and strategies to enhance program funding and sustainability.

20.1 Facilitators and Barriers to Program Implementation

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 20.1.1 Summarize common facilitators and barriers to program implementation.
- 20.1.2 Discuss strategies for identifying facilitators and barriers for a specific intervention.

Even the most well-developed, evidence-based community health programs encounter barriers to implementation that the program team should consider throughout the program planning and implementation processes. The nurse, as part of the program team, strategizes to decrease or eliminate potential barriers, when possible, and enhance **facilitators** of program implementation. A facilitator is a person or thing that makes the implementation of program interventions and activities easier. The program team identifies barriers and facilitators based on community needs assessment, previous literature and research, and previous experience with the target population, community, and similar programs (Fernandez et al., 2022). The program team should choose strategies to decrease barriers based on their impact on the program's effectiveness and the strategy's potential to decrease the barrier (Fernandez et al., 2022). For example, offering bus fare reimbursement to reduce transportation barriers should result in increased recruitment and retention of participants. The program team continues to assess for barriers during implementation and revises intervention strategies to reduce them.

[Table 20.1](#) provides an overview of facilitators and barriers related to intervention planning and implementation, resource utilization, program implementers, and community partners found in two literature reviews (Cooper et al., 2021; Mathieson et al., 2019). The program team considers each to design strategies to enhance the likelihood of the program's success.

Facilitators and Barriers of Program Implementation		
	Facilitators	Barriers
Intervention planning and implementation	<ul style="list-style-type: none"> • Flexible, adaptable interventions • Alignment of intervention with regular organization functions • Timely and relevant • Geographical accessibility • Previous evidence that program intervention improves participant outcomes 	<ul style="list-style-type: none"> • Interventions standardized, not tailored to context or population • Lack of evidence to support interventions • Use of complex interventions • Underestimation of coordination effort and needs • Lack of planning for participant recruitment and retention
Resource utilization	<ul style="list-style-type: none"> • Use of existing resources • Return on investment • Cost and time effective 	<ul style="list-style-type: none"> • Poor availability of resources, including finances, facilities, equipment and materials, and volunteers

TABLE 20.1 Facilitators and Barriers of Program Implementation (See Cooper et al., 2021; Mathieson et al., 2019.)

Facilitators and Barriers of Program Implementation		
	Facilitators	Barriers
Program implementers	<ul style="list-style-type: none"> • Clear understanding and allocation of roles • Strong commitment to the program • Skilled and trained in program topic and program implementation • Established relationships with the target population • Sense of reward 	<ul style="list-style-type: none"> • Competing priorities • Conflict of interest • Ineffective delivery of intervention • High workload • Inefficient knowledge, training, and skill related to program topic or implementation • Complexity of intervention and evaluation
Community members and stakeholders role players	<ul style="list-style-type: none"> • Support and commitment from leaders • Role player engagement • Target population involved in planning • Use of champions from the target population • Effective communication among the program team, partners, and role players • Sense of reward with participation 	<ul style="list-style-type: none"> • Competing priorities • Conflict of interest • Lack of buy-in or interest • Low value placed on program goals • Ineffective communication • Little to no involvement in program planning, participation, or implementation

TABLE 20.1 Facilitators and Barriers of Program Implementation (See Cooper et al., 2021; Mathieson et al., 2019.)

The program team should be aware that facilitators and barriers to program implementation can vary and may depend on the collaborating partners, available resources, current political and social issues, geographical location, time, and participants' values. For example, a program to increase physical activity may be more successful if delivered in the summer instead of during snowy winter months. Cooper et al. (2021) provide the following general recommendations to enhance facilitators and reduce barriers to implementation:

- Ensure community-level coordination and communication to improve the use of existing resources and avoid duplication of services
- Enlist local support of the program to improve community engagement
- Focus on the reliability of program strategies
- Develop standardized but flexible, simple, and regularly evaluated and revised program strategies

20.2 Recruitment and Retention of Program Participants

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 20.2.1 Identify strategies to recruit and retain program participants.
- 20.2.2 Describe ways to tailor recruitment and retention strategies to fit the sociocultural and linguistic needs of target populations.

Recruitment and **retention** of program participants is one of the most important components when planning for implementation because no matter how well a program is planned, it will not successfully meet goals with little or no participation. Recruitment is finding community members from the target population to participate in a community health program. Retention is continued participation in a community health program until its completion. To successfully recruit and retain participants, the program team must develop strategies that utilize evidence from the literature, previous experience with recruitment and retention, and knowledge of the target population's values and beliefs. While several recruitment and retention strategies have been proven to be effective, a combination of strategies is needed to achieve the greatest success (Rural Health Information Hub [RHIhub], 2018b). [Table 20.2](#)

provides a description of recruitment strategies and tasks to complete each strategy.

Recruitment Strategy	Tasks
Know the target population	<ul style="list-style-type: none"> Develop a clear description based on demographics, geography, values, culture, and needs Ensure the program is relevant and meaningful for the target population Address barriers to participation, such as transportation, childcare, stigma, previous negative experiences, and lack of knowledge about program benefits
Develop appropriate materials	<ul style="list-style-type: none"> Use more than one type of recruitment material, which can include flyers, newsletters, newspaper articles, radio or television advertisements, presentations, phone calls, and social media Ensure materials are culturally and linguistically appropriate for the target population
Market strategically	<ul style="list-style-type: none"> Communicate the potential value of participation and what participation entails Develop positive community relationships and use them to spread the word Advertise using sources the target population commonly accesses Build partnerships and collaborations to have a broad base of referral sources for the program
Encourage participation	<ul style="list-style-type: none"> Be enthusiastic in recruitment materials and messages Create program strategies based on the target population's interests Motivate participants by using incentives
Utilize partnerships and members of the target population	<ul style="list-style-type: none"> Use program champions to spread the word and increase interest among the target population Provide partners with recruitment materials for cross-promotion of programs
Revise strategies as needed	<ul style="list-style-type: none"> Assess effectiveness of recruitment strategies and revise if they are not working

TABLE 20.2 Participant Recruitment Strategies and Associated Tasks (See Barnes-Proby et al., 2017. RHIhub, 2018b.)

THEORY IN ACTION

Recruitment Strategies and Challenges

The mission of Denver's MotherWise program is to empower women and their families to thrive during pregnancy and after a baby is born. This program focuses on motherhood, healthy relationships, communication and relationship skills, and connecting with a newborn. The following three short videos describe recruitment strategies and challenges. In the first two videos, program staff share experiences and challenges with participant recruitment. In the third video, participants share why they decided to join the program.

Watch each video, and then respond to the questions that follow.

Video 1

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants>\)](https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants)

- What strategies does the MotherWise program use to recruit participants?

Video 2

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants>\)](https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants)

- What challenges to recruitment did the MotherWise program staff note?
- How did the staff attempt to overcome those challenges?

Video 3

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants>\)](https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants)

1. Why did the participants decide to join the MotherWise program?
2. Based on this information, what recruitment strategies can the nurse use to recruit the target population?

The program's goals will likely be unmet if participants do not complete the program in its entirety. As such, the program team develops retention strategies to achieve participant completion goals. [Table 20.3](#) presents strategies to maintain participation.

Strategies to Promote Participant Retention

Facilitate participant interest and motivation	<ul style="list-style-type: none"> • Ensure interventions are of interest to participants • Provide incentives throughout the program • Incorporate social support into program interventions
Reduce barriers of retention	<ul style="list-style-type: none"> • Incorporate strategies to reduce barriers such as inconsistent or lack of transportation, need for childcare, inconvenient program times, inconvenient program location, negative participant attitudes related to the program, and lack of knowledge
Train program implementers	<ul style="list-style-type: none"> • Ensure implementers' skills enable them to deliver program activities • Assess implementers' attitudes regarding the program and target population and intervene if the attitudes are biased or negative • Train implementers in relationship building to establish trust and connection with participants • Create a welcoming environment • Maintain regular communication with implementers and participants
Incorporate continuous evaluation	<ul style="list-style-type: none"> • Determine why participants enroll in, remain in, and exit the program • Revise retention and program strategies to meet the participants' needs • Solicit participant feedback regarding program activities • Ensure program activities are flexible and varied

TABLE 20.3 Strategies to Promote Participant Retention (See Barnes-Proby et al., 2017; RHhub, 2018a.)

Barnes-Proby et al. (2017) provide a [toolkit \(<https://openstax.org/r/rand>\)](https://openstax.org/r/rand) for the program team to enhance participant recruitment and retention. The toolkit includes five strategies, applicable activities, and examples to guide recruitment and retention planning.

Population Considerations: Health Care Providers

Some community health programs utilize health care providers (HCPs) to deliver interventions and assist with program planning, participant recruitment, and program evaluation. For example, community health workers (CHWs) are public health workers who liaise between health services and the community to improve access to services (Carter et al., 2016). One method to promote CHWs and link clients to them is to have HCPs refer their clients to or write prescriptions for a CHW. In these circumstances, the program team considers the recruitment and retention of HCPs and clients.

Multiple factors influence HCP participation. The program team designs strategies to enhance their recruitment and retention and reduce barriers to their participation. For example, HCPs are more likely to participate in community health programs when they understand the program's value for themselves and their clients, the burden of performing the intervention is low, and the provider's needs match community needs that are met by an evidence-based interventions (Krebs et al., 2021). Conversely, the HCP may be less likely to participate when they lack knowledge and training before program implementation, are inexperienced with client recruitment, have inadequate communication with the program team, and lack time to perform interventions (Krebs et al., 2021).

To successfully recruit and retain HCPs, Krebs et al. (2021) recommend including health care providers in all levels of planning, developing a recruitment strategy at the beginning of the planning process, training HCPs on how to recruit clients and implement the intervention, and using frequent, clear, goal-oriented communication.

Population Considerations: Youth

Facilitators and barriers to recruitment and retention may also differ when youth are the target population. Hull et al. (2022) provide a [resource guide](https://openstax.org/r/teenpregnancy) (<https://openstax.org/r/teenpregnancy>) to enhance recruiting and retaining this demographic in community health programs, with strategies such as these:

- Include youth and parents/caregivers in planning and recruitment
 - Assess youth needs, values, and motivators
 - Collaborate with youth to develop recruitment and program materials, including choice of marketing strategy such as type of social media
 - Host a youth and parent night to provide program information and address questions
 - Train a youth champion to participate in the program and promote the program
- Identify barriers to recruitment and retention
 - Youth may need transportation, provide childcare for siblings, or have scheduling issues due to academics, athletics, or work
 - Consider offering the program during school hours, on weekends, and in shorter sessions
- Establish partnerships with implementation location
 - School-based locations may be best due to fewer transportation issues, youth familiarity with the location, and the potential to incorporate the program into the school schedule
- Provide incentives for participation, such as gift cards, non-tangible items, and/or food
- Ensure the environment and program materials promote a safe and inclusive environment
 - Plan strategies that empower youth and allow their opinions to be heard
 - Clarify program goals, participant expectations, and benefits of participation
 - Translate material into languages and use images that represent the target population
 - Provide opportunities for youth engagement and the communication of values and beliefs
 - Incorporate real-life youth experiences into program activities
 - Ensure program staff are positive, respectful, and supportive of youth

THEORY IN ACTION

Creating Inclusive and Engaging Environments for Youth Programs

[Access multimedia content](https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants) (<https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants>)

Youth participate and remain in community health programs for reasons that may differ from adults. In this video, adolescents describe their reasons for participating in health programs and provide strategies to enhance youth engagement, especially when programs have sensitive topics.

Watch the video, and then respond to the following questions.

1. Why did the adolescents featured in the video participate in an Adolescent Pregnancy Prevention Program?
2. What strategies did the adolescents suggest as ways to create a safe learning environment and promote youth participation?

Population Considerations: Sociocultural and Linguistic Needs

Facilitators and barriers to recruitment and retention may also differ based upon sociocultural and linguistic needs. The program team must understand the target population's needs and incorporate them into recruitment and retention strategies. [Cultural Influences on Health Beliefs and Practices](#) discusses the impact of culture on individual health behaviors, values, and attitudes. [Culturally and Linguistically Responsive Nursing Care](#) and [Culturally and Linguistically Appropriate Program Design](#) describe strategies to meet the target population's cultural

and linguistic needs. Community programs are more effective when:

- program planning, recruitment and retention planning, and program implementation include the target population;
- linguistic needs are met through provision of materials and activities in English and in any other language used by program participants;
- cultural values, beliefs, and needs are incorporated into program strategies; and
- program staff provide a welcoming and inclusive environment, acknowledge and respect cultural differences, and know how to communicate with those from a different culture.

Prevention First (2022) provides a [guide \(<https://openstax.org/r/preventiona>\)](https://openstax.org/r/preventiona) to increase cultural responsiveness of prevention programs. [Table 20.4](#) lists actions to increase personal and program cultural responsiveness and provides examples of related actions.

Action Steps to Increase Cultural Responsiveness	Examples
Build personal cultural awareness and reflect on cultural differences	<ul style="list-style-type: none"> • Evaluate personal attitudes, beliefs, and implicit biases • Seek opportunities to learn about cultures other than your own • Respect cultural differences
Understand diverse community populations and their health needs	<ul style="list-style-type: none"> • Conduct an assessment of community demographic makeup, current needs of all demographics, and community inequities • Assess the target population's cultural and language preferences
Build relationships with diverse community members	<ul style="list-style-type: none"> • Invite community members who are members of the diverse target population to assist with planning and implementation
Create a culturally responsive program structure	<ul style="list-style-type: none"> • Use culturally and linguistically appropriate services (CLAS) to develop policies and procedures • Offer language assistance when needed • Adjust communication style based on the needs of the target population
Incorporate cultural and linguistic strategies into interventions	<ul style="list-style-type: none"> • Create communication that includes images and language that is culturally relevant and easy to read • Incorporate strategies that align with the culture and values of the target population

TABLE 20.4 Actions to Increase Cultural Responsiveness of Community Health Prevention Programs (See Prevention First, 2022.)

THEORY IN ACTION

Incorporating Sociocultural and Linguistic Needs in Community Programs

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants>\)](https://openstax.org/books/population-health/pages/20-2-recruitment-and-retention-of-program-participants)

The PA Fresh Food Financing Initiative is a statewide financing program to assist business owners in opening or expanding stores with the goal of increasing access to healthy, affordable foods and improving economic opportunities for low- to moderate-income community members in Pennsylvania.

Watch the video, and then respond to the following questions.

1. How did the PA Fresh Food Financing Initiative incorporate the community's sociocultural and linguistic needs when marketing the program?
2. How did the PA Fresh Food Financing Initiative incorporate the community's sociocultural and linguistic needs when recruiting and retaining participants?

20.3 Evaluation Strategies

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 20.3.1 Describe an intervention evaluation plan for public health services for individuals, families, and groups.
- 20.3.2 Utilize a systematic process to direct the evaluation of public health interventions.
- 20.3.3 Evaluate outcomes of action plans and interventions, considering implications for practice.

Evaluation of community programs occurs throughout implementation and at the conclusion of a program to improve processes and outcomes. The evaluation provides evidence for decisions regarding the program, such as whether the program should continue, if revisions are needed, or if the program should be discontinued.

Additionally, evaluation may either be mandated by external funders, driven by a need to determine program effectiveness, or both (Centers for Disease Control and Prevention [CDC], 2012). The program team develops a plan for evaluation during the planning phases of community health programming, determining the evaluation methods before beginning intervention activities. Using a systematic process ensures all components of the program are evaluated in an evidence-based way. No matter the process and methods used, the program team evaluates whether goals and objectives of the program are met. If a health program fails to meet the goals and objectives or the community's needs, the team should carefully consider the program's future.

Evaluation Planning for Public Health Programs

Program evaluation is the ongoing, systematic collection, analysis, and use of data to examine program **efficacy**, **effectiveness**, and **efficiency** to make decisions about current and future health programs (CDC, 2012; Issel & Wells, 2018). Efficacy is the “maximum potential effect under ideal conditions” (Issel & Wells, 2018, p. 222). Ideal conditions are difficult to create in community health programs, so efficacy is rarely evaluated. Effectiveness is the community program’s ability to achieve the desired outcome in real-life settings (Issel & Wells, 2018). It is usually measured using statistical data and comparisons to benchmarks. Efficiency occurs when the effect of program interventions, or outputs, are greater than the resources, or inputs, used to provide the intervention (Issel & Wells, 2018). The program team plans for evaluation in order to:

- monitor progress toward program goals and objectives,
- decide if program activities and components are leading to the desired results,
- make comparisons among program participants and other populations,
- provide rationale for further funding and support,
- ensure continuous quality improvement,
- verify program maintenance and efficient use of resources,
- document accountability that the program is fulfilling its purpose and meeting goals, and
- justify sustaining, revising, or discontinuing the program (CDC, 2021).

As noted, the program team plans for evaluation during the program planning process and prior to implementing interventions. Steps to planning for program evaluation include the following:

1. Identify individuals and groups to plan and assist with evaluation.
2. Meet with the program team to determine how to evaluate the program.
3. Examine evaluation types and processes used in the literature.
4. Choose the type of evaluation to be used and a systematic process that aligns with evaluation needs and program goals.
5. Determine what program goals and objectives will be measured, how they will be measured, who will be responsible for collecting data, and what resources are available.
6. Write the program evaluation plan using the types of evaluation and chosen systematic process.

The program team determines which type of community health program evaluation will be conducted. The most common types are **formative evaluation**, **process evaluation**, **outcome evaluation**, and **impact evaluations**. The choice of type depends upon program activities, organizational needs, funder requirements, and the program’s developmental stage.

Formative Evaluation

Formative evaluation occurs during program development to confirm that program interventions are feasible and appropriate (CDC, 2014). Most often, formative evaluation occurs during new program development or when an existing program is revised. Formative evaluation includes a community health needs assessment as discussed in [Assessment, Analysis, and Diagnosis](#).

Process Evaluation

Process evaluation focuses on program implementation processes to determine if the program has been implemented efficiently and as planned. It occurs throughout program implementation, allowing for mid-program revisions and following the program to provide direction for future program improvement. As such, process evaluation should occur to some extent for all community health programs. During process evaluation, the program team describes the program's inputs and outputs. Program inputs are those things and resources required to carry out the program; examples are personnel number and experience, volunteers, informational and technological resources, financial resources and budget, physical location and resources, transportation needs, leadership, time, marketing needs, and other resources needed to complete activities (Issel & Wells, 2018). Program outputs are things accomplished using inputs. Examples of outputs are population reach; number of participants; intervention dose and amount; equipment or incentives distributed; partnerships developed; staff and volunteer hours worked; extent that the budget was followed; quality of information, technological, and physical resources; and staff, volunteer, and participant satisfaction (Issel & Wells, 2018). Most often, the team describes inputs and outputs using qualitative data, but they may use some quantitative data. The program team explains what and how much was accomplished during the program and determines strengths, areas for improvement, and recommendations for ongoing and future program implementation.

Outcome Evaluation

Outcome evaluation assesses the extent to which the program achieves its objectives within the target population and its effect on the target populations' knowledge, attitudes, and behaviors (CDC, 2014). This is an evaluation of the SMART objectives developed during the program development planning stages ([Figure 20.2](#)). [Planning Health Promotion and Disease Prevention Interventions](#) guides the nurse in the development of SMART objectives.

Outcome evaluation should be completed for all community health programs regardless of developmental level. Typically, outcome evaluations are quantitative and include short-, medium-, and long-term measures of change. At times, the team may use qualitative data to provide support for quantitative results. It is recommended that process and outcome evaluation occur simultaneously because if a program objective is not met, it could be a result of implementation process issues (CDC, 2014).

FIGURE 20.2 During outcome evaluation, the team assesses the effectiveness of the SMART objectives on meeting their goals within the target population. (credit: "Maryland Rural Health Day Calvert County Health Department" by Anthony DePanise/Flickr, CC BY 2.0)

Impact Evaluation

Impact evaluation determines the degree to which the community health program has achieved its primary goal (CDC, 2014). It occurs during an existing program, if appropriate, and at the end of a program and most often uses data collected over the long term, including community health assessment data and benchmarks. Most impact evaluations are quantitative. For example, an evaluation might compare pre-program and post-program morbidity, mortality, and health behavior data for the target population and community as a whole.

THEORY IN ACTION

Types of Program Evaluation

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-3-evaluation-strategies>\)](https://openstax.org/books/population-health/pages/20-3-evaluation-strategies)

Various program evaluation types are available to determine if a community health program has been effectively and efficiently implemented. This video describes formative, process, impact, and outcome evaluations.

Watch the video, and then respond to the following questions.

1. How does the nurse and program team determine which type of program evaluation should be used?
2. What evaluation designs are used to conduct program outcome evaluations?

Systematic Processes to Direct Program Evaluation

The nurse in collaboration with the program planning team chooses an evaluation framework or tool to guide evaluation planning. Frameworks and tools provide systematic, evidence-based resources to organize important program evaluation components. Commonly used frameworks and tools include the CDC Framework for Program Evaluation in Public Health (CDC, 1999), Public Health Ontario's steps for evaluating health promotion programs (Ontario Agency for Health Protection and Promotion [OAHPP] et al., 2016), and logic models.

CDC's Framework for Program Evaluation in Public Health

The CDC Framework for Program Evaluation in Public Health is commonly used to summarize elements of program evaluation to assign value and judge a community health program based on evidence. The program team assigns value related to program quality, cost-effectiveness, and significance of the health problem. The framework contains two elements: six steps of program evaluation and standards to assess the quality of evaluation (Figure 20.3) (CDC, 1999). While the program team does not need to conduct the evaluation in a linear sequence, they must thoroughly address each step. [Table 20.5](#) provides examples of activities that occur during each step of program evaluation.

CDC's Framework for Program Evaluation

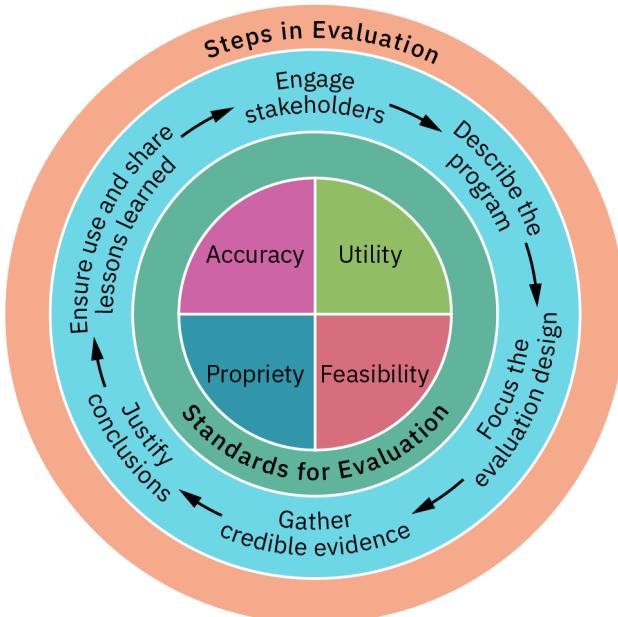

FIGURE 20.3 The Framework for Program Evaluation in Public Health is commonly used to evaluate public health programs. (See CDC, 1999; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Steps of Program Evaluation	Examples of Activities
Engage interested parties	<ul style="list-style-type: none"> • Invite community members and partners identified during the community assessment and program planning process to assist with program evaluation • Make a list of what evaluation data would be useful to each interested party and partner
Describe the program	<ul style="list-style-type: none"> • Write the first portion of the evaluation plan, which includes program mission, objectives, activities, intended outcomes, and program maturity • Create a logic model, if desired, that includes program inputs, activities, outputs, and short-, intermediate-, and long-term outcomes
Focus on the evaluation design	<ul style="list-style-type: none"> • Choose the evaluation design (process, outcome, and/or impact evaluation), considering the program's purpose and maturity
Gather credible evidence	<ul style="list-style-type: none"> • Determine the quantity and quality of data to collect, using multiple data sources to increase the accuracy of evaluation results • Prepare data collection methods, which could include surveys, interviews, focus groups, retrospective document reviews, and observation • Collect data from participants, staff, volunteers, and other relevant parties, and use secondary data sources for benchmarking
Justify conclusions	<ul style="list-style-type: none"> • Analyze and review results, comparing program objectives, benchmarks, literature, and previous implementations, if applicable • Summarize strengths and areas for improvement of the program • Meet with partners to review data and make conclusions regarding the program
Ensure the use and share lessons learned	<ul style="list-style-type: none"> • Share results with program partners, and community

TABLE 20.5 Activities Completed During Program Evaluation (See CDC, 1999).

The program team incorporates the standards of utility, feasibility, propriety, and accuracy throughout program

evaluation. **Utility standards** include determining who needs evaluation information, what information they need, the evaluation's purpose, and how the information will be used (CDC, 1999). **Feasibility standards** involve considering resources available to conduct program evaluation, including money, time, and effort (CDC, 1999).

Propriety standards confirm that program evaluation is fair and ethical (CDC, 1999). **Accuracy standards** substantiate that program evaluation methods, data, and documentation are appropriate and contain accurate information (CDC, 1999). The CDC (2011) provides a [workbook](https://openstax.org/r/cdcb) (<https://openstax.org/r/cdcb>) to guide program teams through the evaluation process.

Public Health Ontario's Steps for Evaluating Health Promotion Programs

Public Health Ontario (OAHPP et al., 2016), a scientific and technical public health organization in Ontario, Canada, recommends 10 systematic steps to evaluate health promotion programs (Table 20.6). Similar to other public health evaluation frameworks, the program team conducts the first steps of program evaluation planning concurrently with program development. The program team engages interested parties, develops the program goals and objectives, determines the target population, creates program strategies and activities, and locates program resources. The organization recommends developing a logic model to represent the program to summarize its main components and to align evaluation questions with program activities (OAHPP et al., 2016). [Planning Health Promotion and Disease Prevention Interventions](#) discusses using logic models in health program planning. Process and outcome evaluation measures should be used. The program team plans to gather data using quantitative and qualitative measures to have substantial information to determine program effectiveness and make decisions regarding health programs. The program team shares findings with interested parties to solicit recommendations and make program decisions. An [introductory workbook](https://openstax.org/r/publichealthontario) (<https://openstax.org/r/publichealthontario>) (OAHPP et al., 2016) is available to assist the program team through evaluation planning and gathering, analyzing, and reporting program data.

Planning	Step 1: Clarify the program
	Step 2: Engage interested parties
	Step 3: Assess resources and evaluability
	Step 4: Determine your evaluation questions
	Step 5: Determine appropriate methods of measurement and procedures
	Step 6: Develop an evaluation plan
Implementation	Step 7: Collect data
	Step 8: Process data and analyze results
Utilization	Step 9: Interpret and disseminate the results
	Step 10: Apply evaluation findings

For more information, see [Evaluating health promotion programs: introductory workbook](https://openstax.org/r/publichealthontarioa) (<https://openstax.org/r/publichealthontarioa>).

TABLE 20.6 Public Health Ontario's 10 Steps to Systematically Evaluate Public Health Programs

Logic Models

Logic models are tools used to visually present the relationships among resources that are used to implement a program, the activities planned, and the intended results of a program (W. K. Kellogg Foundation, 2004). Logic models are also used to map evaluation questions and indicators. If the program team did not create a logic model during the program planning process, it is recommended that the program team create one to assist in evaluation efforts. [Planning Health Promotion and Disease Prevention Interventions](#) describes how to create a health program logic model. After creating a logic model, the team can use it to decide on process and/or outcome evaluation methods and link evaluation questions to logic model components.

THEORY IN ACTION

Logic Models in Program Planning and Evaluation

[Access multimedia content](https://openstax.org/books/population-health/pages/20-3-evaluation-strategies) (<https://openstax.org/books/population-health/pages/20-3-evaluation-strategies>)

Logic models are used during program planning, implementation, and evaluation. This video demonstrates how to develop a logic model and provides an example using a parent training program.

Watch the video, and then respond to the following questions.

1. What are the components of a logic model?
2. How does the nurse connect the logic model to program evaluation and evaluation methods?
3. Using what you have learned regarding types of program evaluation, which components of the logic model align with process evaluation, which components align with outcome evaluation, and which components align with impact evaluation?

Evaluating Outcomes of Action Plans and Interventions

A community health program's outcomes should always be evaluated to determine if program goals and objectives have been met. Data regarding program interventions and activities should be evaluated and analyzed individually and as a whole. The SMART objectives and logic model written during the planning phase, as discussed in [Planning Health Promotion and Disease Prevention Interventions](#), are used to develop evaluation questions and determine data collection techniques.

Data collection techniques include questionnaires to measure knowledge, attitudes, or behavior; observation; interviews; focus groups; and epidemiologic data. The team may collect data from participants, staff, volunteers, and community partners. Participants should always be evaluated to determine knowledge, attitude, or behavior changes. The team may collect pre-implementation or baseline data from epidemiological data, community health assessments, and participant surveys prior to program interventions.

Short-term objectives are often measured immediately following program intervention. Intermediate objectives are measured within a few months following the program, usually within 3 to 6 months. Long-term objectives are usually measured at least one year following the program. The team evaluates impact using community health data. Most often, the nurse and program team use annual epidemiological data or community health assessment data, which is collected at minimum every three years. Benchmarks help determine the impact of programs. For example, in [Planning Health Promotion and Disease Prevention Interventions](#), the nurse and Kenton Hardin County Family Bike Program (KHCFBP) team determined evaluation questions and data techniques from the outcome and impact sections of the logic model. [Table 20.7](#) describes the outcome evaluation of the program.

Outcome as Stated on the Logic Model	Evaluation Question	Data Collection Technique
Short term—Increase participant bike safety knowledge post-program	What was the effect of the KHCFBP on participants' bike safety knowledge?	<ul style="list-style-type: none"> • Pre-survey: five questions to determine baseline bike safety knowledge • Post-survey including the same questions at completion of activities to determine change in knowledge
Short term—Increase participant bike helmet use 30 days post-program	What was the effect of the KHCFBP on participants' report of bike helmet use?	<ul style="list-style-type: none"> • Pre-survey: one Likert-scale question asking frequency of bike helmet use to determine baseline • 30 days post-survey: same question asking frequency of bike helmet use • Pre-survey: one question asking if participant owned a bike helmet
Short term—Increase participant biking frequency 30 days post-program	What was the effect of the KHCFBP on participants' report of bike riding?	<ul style="list-style-type: none"> • Pre-survey: questionnaire asking days per week, average time per day, and intensity of biking for leisure and commuting to determine baseline • 30-day post-survey: same questionnaire

TABLE 20.7 KHCFBP Evaluation Questions and Data Collection Techniques (See Hunsicker, 2020.)

Outcome as Stated on the Logic Model	Evaluation Question	Data Collection Technique
Long term—Increase incidence of biking in Hardin County over the next 5 years	Did incidence of bike riding increase in Hardin County?	<ul style="list-style-type: none"> • 2017 CHA data to determine community baseline • 2023 CHA data to be used for comparison • Healthy People data to use for benchmarking
Impact—Increase physical activity of Hardin County residents	Did physical activity of Hardin County residents increase?	<ul style="list-style-type: none"> • 2017 CHA data to determine community baseline • 2023 CHA data to be used for comparison • Healthy People data and National Physical Activity Guidelines to use for benchmarking

TABLE 20.7 KHCFBP Evaluation Questions and Data Collection Techniques (See Hunsicker, 2020.)

The program team analyzes data after collection. Pre-implementation and post-implementation data are compared. Program evaluation data are also compared to similar program evaluations and national benchmarks. The program team uses this information to evaluate the program's strengths and weaknesses, determines if it has achieved desired outcomes, and examines its efficacy, effectiveness, and efficiency. The program team develops recommendations regarding the program and shares findings and recommendations with community members and partners. Ongoing evaluation of community health programs is necessary to ensure program success, program continuation, and that community needs are being met.

20.4 Communication Strategies

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 20.4.1 Compare information and communication technologies used in the community setting.
- 20.4.2 Describe various communication tools and culturally and linguistically responsive communication strategies.
- 20.4.3 Explain the use of multimedia applications to communicate outcomes.

The nurse uses effective and appropriate verbal and written communication strategies to promote health programs and healthy behaviors, increase awareness of health issues and health programs, recruit and retain program participants, share information with community partners, and disseminate program evaluation findings. The program team strategically develops and employs messages using a variety of tools and technologies. They also determine communication strategies prior to sending any health-related or program message, considering the intended target population's communication needs.

Communication Tools and Technologies Used in the Community Setting

A variety of community tools and technologies are used in the community setting. The program team must weigh the advantages and disadvantages of each when developing a communication plan. They should use multiple communication tools and methods to reach a larger number of the intended target population (Center for Rural Health, 2023; RHIhub, 2018a; U.S. Department of Health and Human Services [HHS], 2014). [Table 20.8](#) lists the types of communication tools and technologies and their advantages and disadvantages.

Communication Tool	Examples	Advantages of Use	Disadvantages of Use
Broadcast media	<ul style="list-style-type: none"> • Television • Radio • Podcast 	<ul style="list-style-type: none"> • Broad audience reach • Message conveyed faster • Opportunity to replay message • Script is used for consistent and controlled messaging • Multiple delivery of message is most effective 	<ul style="list-style-type: none"> • May be limited to single message or to one time per day • One-time communication not always effective • Costly if paid advertisement • Limited reach to some populations (those who do not have access to broadcast media)
Print media	<ul style="list-style-type: none"> • Newspaper • Magazine • Brochures or flyers • Mail • Email 	<ul style="list-style-type: none"> • Broad audience reach • Message conveyed faster • Opportunity to reread message • Script is used for consistent and controlled messaging 	<ul style="list-style-type: none"> • May be limited to single message or to one time per day • One-time communication not always effective • Costly if paid advertisement • Costly if mass-produced for mail • Limited reach to some populations (those who do not have access to print media)
Social and digital media	<ul style="list-style-type: none"> • Internet/websites • Social media • Mobile applications • Video/YouTube • Kiosks 	<ul style="list-style-type: none"> • Reach a large population rapidly • Combines audio and visual • Script or common material is used for consistent and controlled messaging 	<ul style="list-style-type: none"> • May be costly • Limited reach to some populations (those without internet access) • May require monitoring of comments

TABLE 20.8 Advantages and Disadvantages of Communication Tools Used in Public Health Programs (See HHS, 2014.)

Communication Tool	Examples	Advantages of Use	Disadvantages of Use
Outdoor media and public display	<ul style="list-style-type: none"> • Billboard • Mass transit • Community businesses 	<ul style="list-style-type: none"> • Broad audience reach • Message conveyed faster • Opportunity to reread message • Script is used for consistent and controlled messaging 	<ul style="list-style-type: none"> • May be costly • Limited reach for population that does not use the method of transport or visit the community business
Word of mouth	<ul style="list-style-type: none"> • Personal communication • Telephone • Organizational meetings • Community presentations • Partnerships 	<ul style="list-style-type: none"> • Promotes discussion • More effective in promoting change • Effective in reaching intended audience • Messages can be tailored to individual or audience needs • Partnerships and other organizations provide support of the message 	<ul style="list-style-type: none"> • Time-consuming to coordinate communication and arrange presentations • May have limited audience • Message less controlled

TABLE 20.8 Advantages and Disadvantages of Communication Tools Used in Public Health Programs (See HHS, 2014.)

Communication Strategies

The program team develops and follows a systematic process to plan and implement communication strategies. Systematic processes ensure that communication is grounded in evidence, effective, efficient, and able to reach the intended target audience. HHS (2014) and the Center for Rural Health (2023) provide toolkits for health communication planning and implementation.

Four Stages of the Health Communication Cycle

HHS (2014) provides a [workbook](https://openstax.org/r/cancergova) (<https://openstax.org/r/cancergova>) to assist the program team throughout four stages of health communication planning and implementation (see [Figure 20.4](#)).

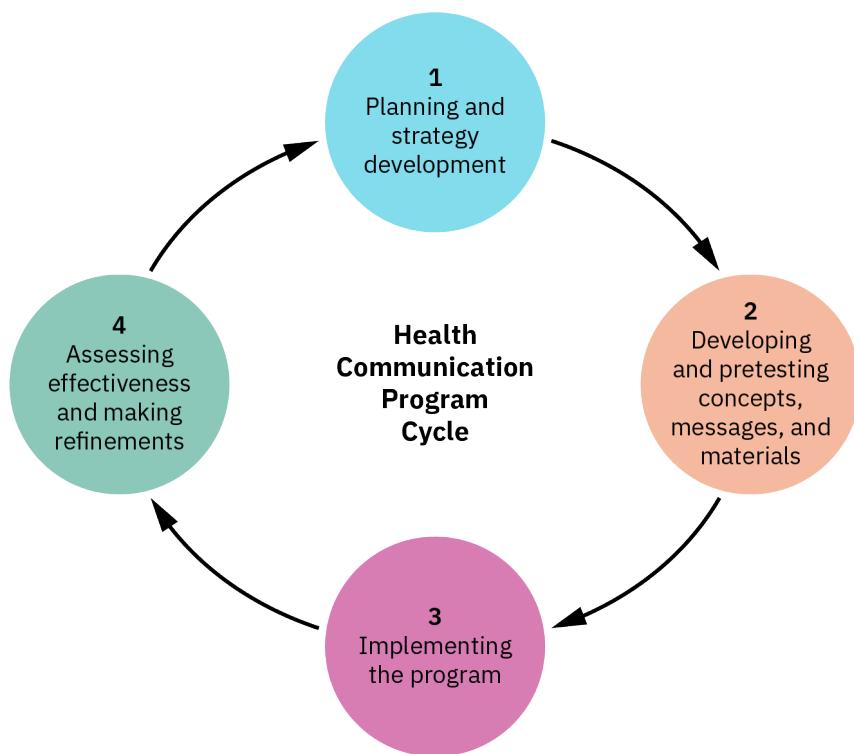

FIGURE 20.4 The nurse and program team use the health communication program cycle to systematically develop and implement health communication. (See HHS, 2014; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

First, the program team decides how to use communication, defines the intended target population, determines communication objectives, plans for evaluation of communication, and drafts communication activities.

Second, they develop messages and materials and collaborate with members of the intended target audience to get feedback and revise messages and materials as needed. The team answers the following questions during the planning stages (HHS, 2014):

- Will this type of communication reach and influence the intended target population?
- Are the chosen types of communication acceptable and trusted by the intended target population?
- Is the type of communication appropriate for the message?
- What is the reach of the type of communication? How many of the target population might be exposed?
- What is the cost of this type of communication?
- Are the resources available to create, maintain, and fund this type of communication?

Third, they implement the message, track exposure of the intended target audience, and continue to solicit feedback to revise the message as needed. Finally, they assess the effectiveness of the message and communication plan and revise them if needed. Strategies for effective health communication include the following:

- Use a variety of communication tools to increase reach (HHS, 2014; RHIhub, 2018a)
- Select evidence-based methods to develop materials and messages (RHIhub, 2018a)
- Incorporate health literacy and cultural needs of the intended target population (HHS, 2014; RHIhub, 2018a)
- Define the goal of the program (HHS, 2014)
- Pretest and revise materials and messages (HHS, 2014)
- Evaluate communication at delivery and throughout implementation (HHS, 2014)

Creating a Communication Plan

The Center for Rural Health provides a [communication toolkit](https://openstax.org/r/ruralhealth) (<https://openstax.org/r/ruralhealth>) to guide the program team to focus “the right message on the right audience at the right time” (Center for Rural Health, 2023, para 1). A systematic communication planning and implementation method leads to efficient and effective communication delivered using the resources of the program budget. The steps of communication plan development include the following:

1. Analysis: Summarize the overarching and communication goals of the program, resources available for communication, and the effectiveness of current communication strategies.
2. Goals & Objectives: Create SMART objectives for communication. [Planning Health Promotion and Disease Prevention Interventions](#) describes SMART objectives.
3. Key Messages: Create three to five central messages for the program.
4. Target Audience: Identify the intended target population and assess communication needs and barriers.
5. Tactics: Choose communication tools and technologies to deliver the message.
6. Implementation Timeline: Set target dates for communication implementation, establish accountability for communication activities, and allocate finances and resources for implementation.
7. Evaluate & Revise: Set dates for evaluation throughout implementation to assess the effectiveness of the communication plan and revise if needed.

Communication Considerations

The program team considers the needs of and barriers to communication with the intended target population. They integrate the target population's health priorities, culture, language, and health literacy into messages and materials used in community health programs.

Cultural and Linguistic Communication Needs

The program team incorporates cultural and linguistic needs of the intended target population into communication to enhance communication effectiveness. Assessment of the target population will provide some information, but inviting key members of the target population to assist with program planning and communication planning will increase the likelihood that the team will identify barriers and meet cultural and linguistic needs. The program team should consider the target population's access to the internet and potential for media exposure as well as what communication technologies members use most often. Various communication tools that are used by the intended target population should be incorporated into the communication plan in order to increase reach (RHIhub, 2018a). Additionally, messages and materials should be available in English and languages most commonly used by the target population and should include concepts, priorities, images, and language that represent the target population. [Culturally and Linguistically Responsive Nursing Care](#) discusses how the nurse incorporates communication and language assistance services and translates written material for community health programs. [Culturally and Linguistically Appropriate Program Design](#) discusses national standards for culturally and linguistically appropriate services and tools to incorporate those standards into community health programs.

CONVERSATIONS ABOUT CULTURE

Stories from the Field: The White Earth Nation

The nurse and program team incorporate culturally and linguistically appropriate messaging and materials into health promotion programs. In this blog, the local public health department incorporated Anishinaabeg culture into messages encouraging COVID-19 prevention and vaccination.

Read the [blog \(<https://openstax.org/r/blogscdc>\)](https://openstax.org/r/blogscdc), and then respond to the following questions.

1. How did the White Earth Public Health team incorporate cultural and linguistic needs into COVID-19 health communication?
2. How did tailoring communication to the intended target population influence the health behaviors of the Anishinaabeg?

Health Literacy and Plain Language

The nurse and program team must also consider the health literacy of the target population. [Assessment, Analysis, and Diagnosis](#) discusses tools to assess health literacy. One method to account for community health literacy is using **plain language** in messages and materials. Plain language is communication that is visually appealing, logically organized, appropriate for the intended audience, and understandable at the first reading (Smith & Wallace, n.d., para 1). The team should follow these principles when using plain language (National Archives, 2023):

- Write for the intended target audience.

- Begin with the key message.
- Keep it short.
- Write in the active voice.
- Use common language, not medical terminology.
- Omit words that are not needed to convey the message.
- Use headings, lists, and tables.
- Proofread and have a member of the intended target audience review.

THEORY IN ACTION

Demand to Understand: How Plain Language Makes Life Simpler

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-4-communication-strategies>\)](https://openstax.org/books/population-health/pages/20-4-communication-strategies)

In this 19-minute TEDx Talk, Deborah Bosley discusses the importance of using plain language when communicating health information and suggests strategies to improve clarity of health communication.

Watch the video, and then respond to the following questions. If time does not allow full viewing, watch at 8:50 for the definition of plain language and then from 14:37 to the end for strategies.

1. Why is it important to use plain language when developing messages and materials for community health programs?
2. What strategies are recommended to ensure health communication is delivered using plain language?

20.5 Funding and Sustainability

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 20.5.1 Define sustainability.
- 20.5.2 Consider the influence of efficiency, value, and cost on program continuity and sustainability.
- 20.5.3 Examine how external and internal funding streams and levels can influence program continuity.
- 20.5.4 Explain the relevance of creating a sustainability plan early in the planning and implementation stages.

The goal of health promotion and disease prevention is to deliver community health programs that effectively and efficiently meet community needs. Funding and resources are required to deliver community health programs. The program team must address funding needs and program **sustainability** at the beginning of the program planning process and before the end of the initial funding cycle. Sustainability is the continuation of community health programs because the program is valued, cost and resource efficient, effective, and supported by the community (Georgia Health Policy Center, 2011; U.S. Department of Housing and Urban Development [HUD], 2012). The program team enhances sustainability by decreasing dependence on one funding source and shifting to one or more new funding streams. Sustainability goals may differ depending upon the developmental stage of the program. For example, newer programs focus on the continuation of activities once the initial funding stream ends, and experienced programs may focus on expanding program reach, building new partnerships, and promoting policy initiatives (HUD, 2012). Additionally, sustainability does not refer to the continuation of a program using the original strategies and activities. Most often sustainable programs evolve over time to adjust to changing funding, support, and community needs (Georgia Health Policy Center, 2011). Sustainability is influenced by (HUD, 2012):

- Efficiency and effectiveness of program activities
- Community support
- Partnerships that maximize use of resources
- Funding diversification
- Ability to draw new funds and partnerships
- Understanding of the overall cost savings associated with program implementation and improvement of community health status

External and Internal Funding Streams

The program team must identify funding to support new and continuing community health programs. The nurse must be aware of possible external and internal funding streams and have experience with soliciting funds for community health programs (see [Table 20.9](#)). Frequently, community health programs begin with funding support from one stream that does not continue throughout the program's lifetime, so it is necessary to identify diverse funding streams to enhance program sustainability.

Funding Stream	Description	Nurse's Role in Acquiring Funds
Grants	Funds provided by a government source or private foundation for a specific purpose and for a specified time frame	The nurse may locate potential grants, write grant applications, communicate with funders, and carry out activities, or deliverables, specified within the grant.
Indirect funding	Resources, such as volunteers, equipment, materials, or funding, provided by an external source	The nurse may solicit or recruit volunteers, materials, etc.
Contributions or sponsorships	Businesses, social and civic clubs, churches, or individuals make financial or resource donations.	The nurse may provide presentations or communicate with potential sponsors to solicit funds. Sponsorships and contributions are often communicated as funders in program messaging and materials.
Government budgets	Local, state, and federal monies are factored into the annual budget and are set aside for community health program funding. The funds are usually acquired via taxes and fees to community residents.	The nurse may advocate for additional annual monies to be provided for community health programs and health promotion activities.
Fundraising events	Sporting events, such as golf outings or marathons, or lunch/dinner events are held to raise funds to support community health programs.	The nurse may plan and implement events.
Earned income	Funds earned through internal streams, such as fee for service, consultation, reimbursement from second party payers, or product sales are used to support community health programs.	The nurse may provide services that contribute to the internal streams, such as vaccination clinics.

TABLE 20.9 Funding Streams and the Nurse's Role in Acquiring Funds (See Georgia Health Policy Center, 2011.)

THEORY IN ACTION

Funding Public Health Projects

[Access multimedia content \(<https://openstax.org/books/population-health/pages/20-5-funding-and-sustainability>\)](https://openstax.org/books/population-health/pages/20-5-funding-and-sustainability)

The nurse must understand how to procure funds for public health programs. This video introduces funding for public health projects and describes how funding agencies and funding cycles are structured.

Watch the video, and then respond to the following questions.

1. Why should the nurse understand the funding agency's objective before applying for a grant?
2. What is the general process of grant application and funding?

Sustainability Planning

The program team begins intentionally planning for sustainability during program planning and development. The sustainability plan is supported by program evaluation and achievement of program objectives. The program team

uses evaluation data to decide which program activities will continue following a grant period or when initial funds have been depleted (Georgia Health Policy Center, 2011). Sustainability efforts are strengthened if a program demonstrates effectiveness, positive results, strong leadership, and community engagement (HUD, 2012). Program growth and sustainability are promoted when the program team focuses on evaluation and continuous quality improvement, organizational capacity, expansion of partnerships, systems or policy change, identification of new funding streams, and diversification of sources of funding (RHIhub, 2022). Studies have shown that sustainable programs are adaptable, have leadership that develops a clear, strategic purpose for grants and commit to providing resources, include cross-sector partnerships, consider community needs and demand, use data to show program impact, and align with the current social and political environment (Georgia Health Policy Center, 2020).

The nurse and program team can use the Georgia Health Policy Center (2011) [step-by-step workbook](#) (<https://openstax.org/r/ruralhealthinfoa>) to guide sustainability planning. Generally, the program team answers the following questions when planning for sustainability (Georgia Health Policy, 2011; HUD, 2012):

1. What criteria will be used to determine continuation? For example, criteria could include that the program
 - meets community needs,
 - is valued by the community,
 - has positively impacted participants and the community,
 - achieves objectives and goals,
 - uses cost-effective program delivery,
 - has a return on investment,
 - has sufficient partner and community support, and
 - can access needed resources.
2. Has the program met sustainability criteria?
3. What will continue to be offered—all or part of a program?
4. Who is needed to continue the program (leadership, staffing, and partnerships)?
5. Can support for the program and partnerships be expanded? How?
6. What is the cost of the program (budgeted line items and overall cost)?
7. What are current and potential funding strategies?
8. Are the funding strategies diversified?

RHIhub (2022) offers several [resources for sustainability planning](#) (<https://openstax.org/r/ruralhealthinfob>), including toolkits for specific types of community health programs. For example, the maternal health toolkit lists potential federal, state, and other funding sources.

To successfully implement and sustain community health programs, the program team must consider facilitators and barriers to program implementation to plan interventions that will enhance facilitators and reduce barriers. Participant recruitment and retention is an important consideration. Without program participants, a program would not effectively meet its goals and objectives. Recruitment and retention are facilitated when sociocultural and linguistic needs are met. Systematic evaluation of the community health program provides evidence of efficacy, effectiveness, and efficiency in order to make decisions about the current and future programs. Program evaluation strategies depend upon the needs of the program team and community partners and on the developmental level of the program. Outcome evaluation should occur regardless of the developmental level. Most often process evaluation occurs along with outcome evaluation so that the program team can make inferences about outcome results. Effective communication, diverse funding streams, and sustainability planning are key in promoting and maintaining community health programs.

Chapter Summary

20.1 Facilitators and Barriers to Program Implementation

To successfully implement community health programs, the program team strategizes to decrease potential barriers and enhance facilitators of implementation. Facilitators and barriers are identified based on community needs assessments; intended target population assessment of sociocultural, linguistic, and literacy needs; literature and research; and previous experience with program implementation.

20.2 Recruitment and Retention of Program Participants

The program team utilizes strategies to enhance participant recruitment and retention. Common recruitment strategies include the target population in planning, develop culturally and linguistically appropriate materials, and utilize strategic marketing and partnerships to promote programs. Common retention strategies are facilitating participant motivation, ensuring program implementers have the skills and knowledge to deliver the program, soliciting participant feedback, and reducing transportation, childcare, location, and timing barriers. Strategies vary based upon the population.

20.3 Evaluation Strategies

Evaluation of community health programs occurs to improve processes of implementation and program outcomes, assist in decision-making regarding the program, and meet funder requirements. A systematic process is used to evaluate the efficacy, effectiveness, and efficiency of the program components and the program as a whole. Formative, process, outcome, and impact are types of program evaluation that may be conducted. The CDC's Framework for Program Evaluation in Public Health, Public Health Ontario's steps for evaluating health promotion programs, and

Key Terms

accuracy standards benchmarks that substantiate that program evaluation methods, data, and documentation are appropriate and contain accurate information

effectiveness ability of a community program to achieve the desired outcome in real-life settings

efficacy maximum potential effect under ideal conditions

efficiency occurs when the effect of program interventions, or outputs, are greater than the resources, or inputs, used to provide the

logic models are common frameworks and tools used in community health program evaluation. These tools direct the program team to align goals and objectives with type of evaluation, evaluation question, and data collection technique. The evaluation results are shared to make decisions, revisions, and recommendations for the program.

20.4 Communication Strategies

The program team develops a communication plan to deliver effective and appropriate messages and materials. Various communication tools and technologies are used to expand the reach of communication. A communication plan includes developing and testing messages and materials, implementing communication, and assessing effectiveness and revising messages and materials as needed. Cultural, linguistic, and literacy needs of the intended target population are considered when developing communication. It is recommended that plain language and concepts, images, and languages that represent the target population are used in messages and materials.

20.5 Funding and Sustainability

The program team must plan for funding and sustainability in order to continue community health programs. Sustainability planning includes evaluation of the efficiency, value, and cost of a program. Diversification of funding streams enhances sustainability efforts. Potential funding streams include grants, indirect funding, contributions or sponsorships, government budget lines, fundraising, and earned income. Sustainable community health programs are flexible, have strong leadership, include cross-sector partnerships, incorporate community needs and demand, use evidence to show program impact, and align with the current political and social environment.

interventions

facilitator person or thing that makes implementation of program interventions and activities easier

feasibility standards benchmarks involving the consideration of resources, which include money, time, and effort, that are available to conduct program evaluation

formative evaluation an assessment that occurs during program development to confirm that program interventions are feasible and appropriate

impact evaluation an assessment to determine the degree to which the community health program has achieved its primary goal

outcome evaluation an assessment of the extent to which the program achieves its objectives within the target population and the effect the program has on the target populations' knowledge, attitudes, and behaviors

plain language communication that is visually appealing, logically organized, appropriate for the intended audience, and understandable at the first reading

process evaluation an assessment focused on program implementation processes in order to determine if the program has been implemented as planned and in the most efficient way

program evaluation ongoing, systematic collection, analysis, and use of data to examine program

efficacy, effectiveness, and efficiency to make decisions about current and future health programs

propriety standards criteria used to confirm that program evaluation is fair and ethical

recruitment finding community members from the target population to participate in a community health program

retention continued participation in a community health program until completion

sustainability continuation of community health programs by decreasing dependence on one source of funding and shifting to a new funding stream because the program is valued, cost and resource efficient, effective, and supported by the community

utility standards specifications for determining who needs evaluation information, what information is needed, the purpose of evaluation, and how the information will be used

Review Questions

1. A nurse is planning a community program to decrease youth substance misuse. Which strategy could the nurse implement to promote participant recruitment?
 - a. Hold meetings in evening at a local church
 - b. Integrate activities into the regular school schedule
 - c. Collaborate with the school principal when developing materials
 - d. Assess parent and guardian perceptions of youth substance misuse

2. The nurse evaluates how activities were implemented and what resources were needed to carry out a community health program. Which type of evaluation is the nurse using?
 - a. Formative
 - b. Process
 - c. Outcome
 - d. Impact

3. A nurse using the CDC's Framework for Program Evaluation in Public Health has chosen the evaluation design in collaboration with program partners. Which evaluation activity represents the next step using the framework?
 - a. Developing program goals, objectives, and activities
 - b. Creating a logic model of the community health program
 - c. Sharing results with program partners and the community
 - d. Preparing data collection tools to gather from multiple data sources

4. The nurse is developing communication materials for a community health program. What action should the nurse take to create materials incorporating the needs of the intended target population?
 - a. Use medical terminology to increase health literacy
 - b. Write in the passive voice and end with the key message
 - c. Plan to only release the communication on social media sites
 - d. Use images and language that represent the target population

5. Which of the following is an internal funding stream the nurse could utilize for community health programs?
 - a. Grants
 - b. Sponsorships
 - c. Earned income

- d. Indirect funding
- 6. When planning a community health program, which is the best method to ensure the target population's sociocultural and linguistic needs are met?
 - a. Incorporate knowledge about the culture into activities
 - b. Hire an interpreter to assist with program delivery
 - c. Include community members in program planning and implementation
 - d. Ensure staff are culturally competent
- 7. The nurse is analyzing the sustainability of a community health program. Which finding would indicate that a program may need to be discontinued?
 - a. Partner support and resources are adequate.
 - b. New funding sources need to be identified.
 - c. Program goals and objectives have been met.
 - d. Attendance is low due to community lack of interest.
- 8. Which data source would a nurse use to perform an impact evaluation of an existing community health program?
 - a. Participant surveys completed prior to and on the final day of the program
 - b. Participant surveys completed prior to and 90 days following the program
 - c. Local community health assessment prior to and following the program
 - d. Local community health assessment following program conclusion
- 9. Which action by the nurse is an example of community health program sustainability?
 - a. Soliciting another funding source to continue a program
 - b. Using the same funding source to offer a program
 - c. Decreasing the number of community partners
 - d. Discontinuing the program due to lack of interest
- 10. The nurse is looking at different tools to communicate efficiently with the community. Which health activity would be appropriate for the nurse to communicate using a billboard?
 - a. Providing health education to an identified at-risk population
 - b. Increasing community awareness of common health issues
 - c. Prompting discussion regarding common health issues
 - d. Recruiting partners for a community health program

CHAPTER 21

Cultural Influences on Health Beliefs and Practices

FIGURE 21.1 The ever-increasing multicultural population in the United States requires nurses to recognize and appreciate cultural differences in health care values, beliefs, and customs. (credit: modification of work by Michael Quinn/NPS/Flickr, CC BY 2.0)

CHAPTER OUTLINE

- 21.1 Race, Ethnicity, Culture, and Nationality
 - 21.2 Cultural Groups and Formation of a Cultural Identity
 - 21.3 The Role of Culture in Shaping Health Beliefs and Practices
 - 21.4 Overview of Cultural Views and Practices
 - 21.5 Culture Matters in Addressing Health Inequalities
-

INTRODUCTION On a bustling night shift at an urban hospital in a diverse city, Nurse Sampson is ready to care for a varied group of clients, each with their own cultural and personal background. Using a client-centered approach, Nurse Sampson is committed to providing the best care possible.

The increasingly multicultural U.S. population highlights the need for nurses to recognize and appreciate cultural differences in values, beliefs, and customs. Providing culturally sensitive care improves health outcomes and ensures that health care is accessible and equitable for all clients. By embracing culturally responsive care and cultural humility, nurses can navigate the complexities of cultural diversity and deliver effective and compassionate care, which can contribute to a more equitable and accessible health care system for everyone.

The chapters in this unit consider many facets of culturally congruent care, including the need for this type of care, guiding theoretical perspectives, approaches, and tools nurses can use. This chapter explores the relationship between culture and health and addresses how cultural factors may influence health beliefs, behaviors, practices,

and health outcomes. It emphasizes the importance of recognizing that clients may have different expectations regarding communication, space, social organization, time, dietary practices/preferences, and environmental control from those held by the nurse, health care provider, and dominant culture. [Transcultural Nursing](#) explores cultural models and the significance of cultural assessment in the provision of culturally sensitive care for individuals from diverse backgrounds. [Culturally and Linguistically Responsive Care](#) examines the journey toward becoming a culturally responsive nurse, while [Culturally and Linguistically Appropriate Program Design](#) provides practical tools for culturally responsive care. Finally, [Managing the Dynamics of Difference](#) applies the nursing process to a nurse's personal journey of becoming more culturally responsive.

21.1 Race, Ethnicity, Culture, and Nationality

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 21.1.1 Describe the racial and ethnic makeup of the United States.
- 21.1.2 Explain the concept of diversity.
- 21.1.3 Identify the groups utilized in diversity calculations.
- 21.1.4 Discuss the ways in which race and ethnicity describe diversity.
- 21.1.5 Differentiate between race, ethnicity, culture, and nationality.

Diversity in the United States is not new. Before the country's founding, Native Americans lived in what is now the United States, and settlers immigrated from England, France, Germany, the Netherlands, Poland, Scotland, and other European countries. At the start of the American Revolutionary War in 1775, "more than 250,000 Native Americans lived east of the Mississippi River. They formed more than 80 nations and spoke dozens of languages and dialects" (Museum of the American Revolution, n.d., para. 1).

The U.S. population continues to increase—by 2060 it is projected to number 417 million, and as the population grows, it is becoming increasingly more diverse (U.S. Census Bureau, n.d.). To meet the needs of this multicultural population, nurses must recognize and appreciate the differences in health care values, beliefs, and customs in a diverse society.

The Difference Between Race, Ethnicity, Culture, and Nationality

Race, ethnicity, culture, and nationality are distinct but interconnected concepts that influence how individuals identify and interact. Race is a form of social categorization often based on physical appearance, while ethnicity is tied to social and cultural affiliations (A. García, 2018; J. D. García, 2020). Culture is a broader concept that encompasses learned and shared patterns of behavior, and nationality pertains to one's country of citizenship. These factors can influence human behaviors, beliefs, values, and interactions in a community (Smith & Bond, 2019).

Though these terms have distinct meanings, they are often used interchangeably. As discussed in [Structural Racism and Systemic Inequities](#), **race** is a societal construct that is commonly defined by physical characteristics, such as bone structure, skin, hair, or eye color, as well as social factors and cultural backgrounds. However, race is not biologically predetermined, and different racial categories may not reflect shared genealogy. Unlike heritage or ancestry, race is assigned rather than inherent or chosen. It is a dynamic and evolving concept that is influenced by historical, societal, and political contexts (Jones & Bullock, 2019). The use of racial categories in demographic counts can be traced back to the 1790 U.S. Census.

RACE: A MYTH AND AN ILLUSION

[Access multimedia content \(<https://openstax.org/books/population-health/pages/21-1-race-ethnicity-culture-and-nationality>\)](https://openstax.org/books/population-health/pages/21-1-race-ethnicity-culture-and-nationality)

Though racial categories have been used in the U.S. Census for hundreds of years, these categories are social constructions, rather than biological facts.

Read [RACE: The Power of an Illusion](https://openstax.org/r/pbsorg) (<https://openstax.org/r/pbsorg>), watch the video "The Myth of Race, Debunked," and then respond to the following questions.

1. How have racial definitions changed over time?
2. How do demographic shifts and the sociopolitical climate influence the definition of racial categories?
3. What, if anything, surprised you in this video?

Unlike race, the social and cultural groups one belongs to determine their ethnicity. **Ethnicity** is a fluid concept rooted in shared cultural traits such as language, religion, nationality, history, or other cultural factors that bind individuals into distinct social groups. Ethnicity is inherited and shared among a group. Like race, the definition of ethnicity evolves over time and can be broadly or narrowly constructed. While everyone is “born into” certain features of ethnicity, personal experiences and societal influences can reshape these characteristics (A. García, 2018; J. D. García, 2020).

Culture has no single definition and is both universal and personal. Definitions in the literature indicate that culture:

- is learned, shared, and transmitted (McFarland, 2018);
- involves patterned responses to behavior (Giger & Haddad, 2021);
- is a historically transmitted pattern of meaning (Forbes & Mahan, 2017);
- is a learning process (Spradley et al., 2016); and
- distinguishes the members of one group of people from others (Hofstede, 2011).

Nationality denotes an individual’s country of citizenship. In the 19th century, nations were formed based on ethnic nationalism, which presumed a shared ethnic origin among their people. Examples include Britain, Germany, Italy, and Sweden. [Table 21.1](#) compares the concepts of race, ethnicity, culture, and nationality.

Social and cultural factors play a significant role in shaping the dynamics of societies. These factors encompass a broad range of elements that influence human behaviors, beliefs, values, and interactions in a community (Smith & Bond, 2019).

	Race	Ethnicity	Culture	Nationality
Definition	A social construct used to categorize or divide individuals based on physical traits, social factors, and cultural backgrounds; not biologically based	Based on everyday ancestral, cultural, national, and social experiences	Based on beliefs, values, norms, and practices that are learned and shared generation by generation	Refers to the country of citizenship
Examples	Black, White, Asian, etc.	Albanian, Amish, Cherokee, English, Polish, Libyan, etc.	American culture, Arab culture, British culture, etc.	Afghan, Chinese, Cuban, Italian, French, etc.

TABLE 21.1 Comparison of Race, Ethnicity, Culture, and Nationality

The Racial and Ethnic Makeup of the United States

Over the last 100 years, the racial and ethnic makeup of the United States has changed dramatically. In fact, in just 10 years, the country has experienced a 276 percent growth in the population of people identifying as two or more races (Jones et al., 2021). While these changes may be due, in part, to a change in the way the 2020 U.S. Census framed questions about racial and ethnic identification, both the change in the way the questions were asked and the responses suggest a shift in the way Americans think about their racial and ethnic identities toward the embrace of more nuanced multiethnic and multiracial identities. In 2021, the United States was more diverse than in 2010, with the Hispanic/Latino population growing the most, increasing by 2.5 percentage points to 18.9 percent. Conversely, the White, non-Hispanic/Latino population experienced the most significant decrease, dropping by 4.5 percentage points to 59.3 percent. As discussed in [Demographic Trends and Societal Changes](#), the United States will become a majority-minority nation by mid-century because of a decreasing non-Hispanic White population and an increasing minority population (USAfacts, 2022) ([Figure 21.2](#)).

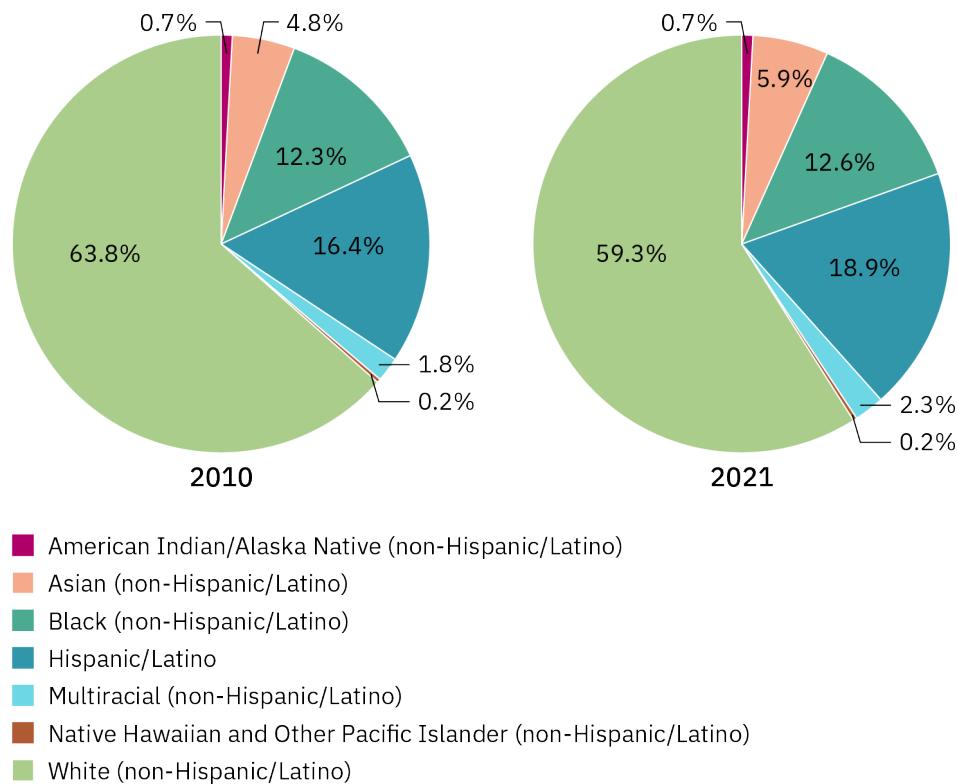

FIGURE 21.2 Between 2010 and 2021, the Hispanic/Latino populations grew the most, increasing by 2.5 percentage points to 18.9 percent. The White, non-Hispanic/Latino population had the most significant decrease, dropping by 4.5 percentage points to 59.3 percent. (data source: U.S. Census; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Diversity refers to the relative size and representation of different racial and ethnic groups—the heterogeneous rather than homogenous nature of the mix of these groups in a population. The U.S. Census uses the following groups in its diversity calculations (Jensen et al., 2021):

- Hispanic/Latino
- White alone, non-Hispanic/Latino
- Black or African American alone, non-Hispanic/Latino
- American Indian and Alaska Native alone, non-Hispanic/Latino
- Asian alone, non-Hispanic/Latino
- Native Hawaiian and other Pacific Islander alone, non-Hispanic/Latino
- Some other race alone, non-Hispanic/Latino
- Multiracial, non-Hispanic/Latino

The United States is a **heterogeneous society**, with people from various ethnicities, cultures, and religions coexisting. Belgium is a European example of a heterogeneous society. Belgium is known for its linguistic diversity, with three official languages: Dutch (Flemish), French, and German. The country is divided into distinct regions, including Flanders, Wallonia, and the Brussels-Capital Region, each with its own language and cultural characteristics. In addition to these linguistic divisions, Belgium is home to immigrant communities from various countries, further contributing to its heterogeneous nature (Droixhe & Gsir, 2017). India is another example of a heterogeneous society. According to the most recent Census of India data, from 2011, the country has 30 different native languages. The most spoken language, Hindi, is spoken by just 43.6 percent of the population. The next five most spoken languages are Bengali (8 percent), Marathi (6.9 percent), Telugu (6.7 percent), Tamil (5.7 percent), and Gujarati (4.6 percent) (Office of the Registrar General and Census Commissioner, India, 2011). In terms of religious diversity, while the country is more than 80 percent Hindu, it also has large Buddhist, Jain, and Muslim populations and the largest Sikh population in the world (Kramer, 2021). In 2012, the U.S. State Department estimated that there were more than 2,000 ethnic groups in India (U.S. Department of State, 2012).

In contrast, countries such as Japan and South Korea are primarily made up of one dominant culture, making them **homogeneous societies**. Japan is predominantly made up of people of Japanese ethnicity, though there are also

minority groups such as Ainu, Ryukyuan, and Korean communities that contribute to the country's cultural diversity. South Korea is also primarily comprised of people of Korean ethnicity, with other minority groups making up a smaller proportion of the population.

The coexistence of diverse religious, ethnic, or cultural groups in a society, all adhering to the same rules, is called **multiculturalism** (Longley, 2021). In contrast, in **cultural pluralism**, there is one dominant society in which all minority groups participate fully (Clayton, 2020). *Pluralism* refers to multiple cultures existing in the same place with their own unique traditions and regulations. There is typically a dominant culture in pluralism, whereas no single culture holds more importance than the others in multiculturalism.

The success of immigrants in their new countries is greatly influenced by their ability to assimilate, integrate, and/or adapt. The United States is often associated with multiculturalism because of the religious, ethnic, and cultural diversity of its population. However, as a pluralistic rather than truly multicultural society, the United States has a dominant culture and allows minority groups to maintain their unique identities in the larger society. This coexistence of a dominant culture and diverse minority groups can result in positive aspects, such as cultural enrichment, but it can also create challenges, including differential treatment and variations in societal rules (Ziólkowska-Weiss, 2020). Despite efforts to promote inclusivity and tolerance, disparities may persist due to deep-rooted structures and systemic issues (Solomon et al., 2019). These issues are discussed in more detail in [Structural Racism and Systemic Inequities](#).

While *race* and *ethnicity* are commonly used terms to describe diversity, they do not necessarily describe a person's cultural identity. A person can have multiple racial and ethnic backgrounds, and reducing culture to a broad categorical or dichotomous variable in a culturally pluralistic society can hide the individual differences that exist in groups of people. Therefore, it is essential to recognize the underlying intragroup variations and acknowledge the complexity of cultural identity in a diverse society (Singer, 2012; Singer et al., 2016). Culture is much more than a racial or ethnic category.

21.2 Cultural Groups and Formation of a Cultural Identity

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 21.2.1 Explain the concept of culture.
- 21.2.2 Distinguish between nonmaterial and material culture.
- 21.2.3 Identify cultural traits.
- 21.2.4 Describe the visible and invisible elements of culture.
- 21.2.5 Differentiate between individualistic and collective cultural traits.

As discussed previously, culture has no single definition and is both universal and personal. The best way to conceptualize culture is as a set of learned patterns of beliefs, behaviors, ideas, philosophies, and practices that are shared. These cultural elements are not constant but are formed throughout an individual's lifetime.

Cultural Groups, Patterns, and Expression

A **cultural group** shares a core set of beliefs, patterns of behavior, and values. These groups may be large or small, but their thinking and behavior identify them. Cultural groups are defined by not only racial or ethnic background but also by linguistic, religious, spiritual, geographical, and/or sociological characteristics (Office of Minority Health, 2013). Cultural groups consist of **subcultures**, also known as aggregates; a subculture shares distinguishing characteristics that may identify with aspects of its larger parent culture. For example, children born between the early 2010s and the mid-2020s are part of Generation Alpha, a subculture based on generation.

Cultural patterns of behavior are socially acquired, not genetically inherited. Patterns specific to a particular culture are learned through the process of **enculturation**. Social institutions such as the family, religion, the education system, peer groups, community, and the media play a role in enculturation. Each culture shares a particular set of cultural traits, such as rituals, which serve as the fundamental structures of culture. Cultural traits are material (objects or artifacts) and nonmaterial (ideas or values). In each culture, thousands of cultural traits influence identity formation (Fabietti, 2016). Over time, the shared beliefs, values, and norms create cultural patterns that distinguish the group from other cultures.

Culture is like an iceberg with visible and hidden elements (Figure 21.3). Visible cultural elements include dress, food, language, and art. Visible elements are tangible. However, visible elements only make up about 10 percent of cultural identity. The other 90 percent is made up of hidden or invisible elements. Invisible elements are the intangible parts of a culture, such as communication styles, rules, etiquette, views of time and space, and emotional regularity (Hall, 1976). These elements are the most powerful features of culture, shaping perceptions, attitudes, beliefs, and values. Culture informs beliefs regarding what is true and false; values of right and wrong; attitudes, including likes and dislikes; and behaviors. It is from these cultural influences that people's identities are formed (University of Minnesota Libraries Publishing, 2016).

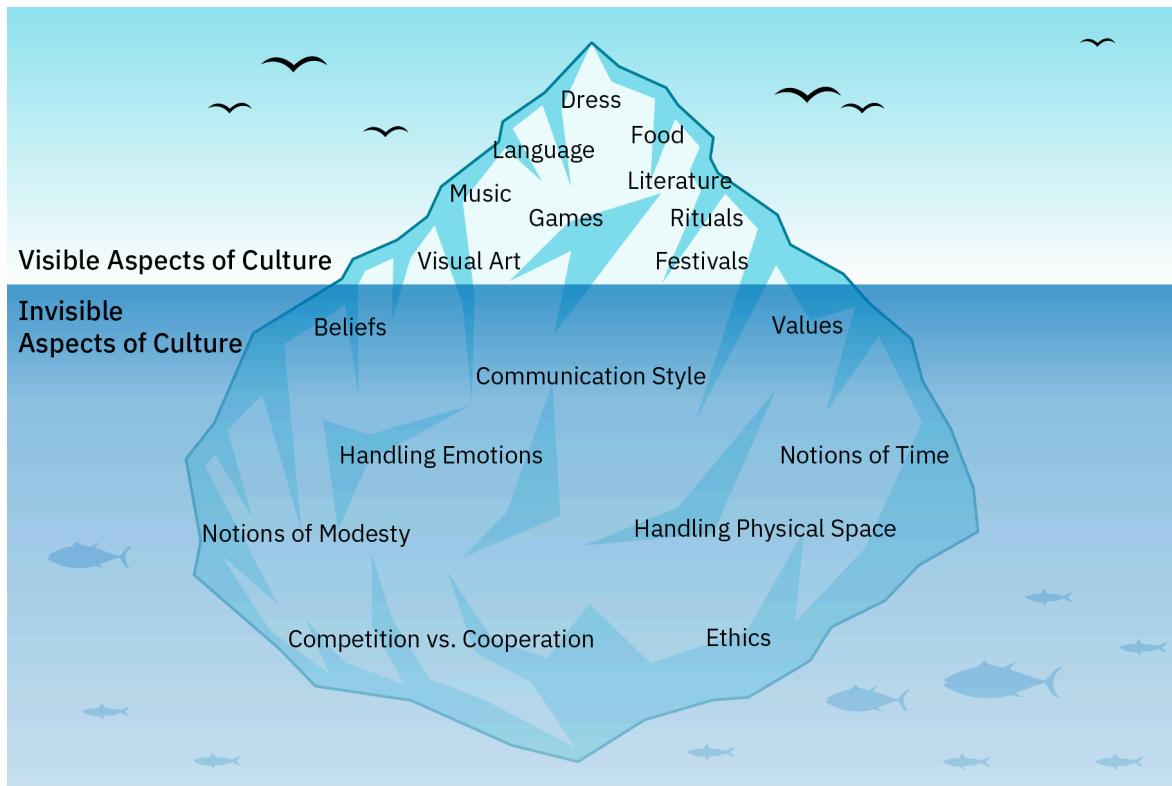

FIGURE 21.3 Culture has visible and invisible elements. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Culture informs how one is socialized to interact with other people and communities. For example, in an individualistic culture, individuals are socialized to be independent and psychologically separate from others. In comparison, collectivist cultures encourage interdependence and promote the interests of the collective over the individual (Fatehi et al., 2020).

For example, Western cultures, including the United States, emphasize the *self* as independent and separate from others. This independence is expressed by focusing on *self-goals*, wishes, and desires. Common expressions in an individualistic culture are *self-fulfillment* and *self-actualization*. In comparison, some Asian cultures emphasize interdependence and fitting in to maintain harmony (Fatehi et al., 2020).

People express their culture in a variety of ways. Examples are traditions, symbols, clothing, foods, and ways of doing things or behaving. From a theoretical perspective, there are two types of culture: nonmaterial and material. Nonmaterial, or symbolic, culture includes elements such as values, beliefs, symbols, and languages. In contrast, material culture relates to physical objects such as clothing, utensils, and tools.

Cultural Identity

Personal identity is influenced by the cultural groups an individual belongs to that form their social identity. These cultural groups may be involuntary (family) or voluntary (book club). Social identities represent who an individual is and who they are not. Food, clothing, celebrations, and religion are all manifestations of culture, and each plays a role in shaping and reinforcing cultural identity and community. The interconnection of an individual's cultural, personal, and social identities helps form their self-concept and their cultural identity.

- **Food:** Different cultures have different culinary traditions in the types of popular foods and the ways of preparing and consuming food. For example, in many parts of Asia, it is customary to eat with chopsticks, while in the Western world, using a fork and knife is more common. In some cultures, it is considered rude to waste any part of an animal when cooking. Some cultures also believe that certain foods or drinks have medicinal or spiritual properties.
- **Clothing:** is another important aspect of culture; different cultures have different dress codes and styles. For example, in some cultures, it is customary for women to cover their heads or wear long dresses or skirts, while men in some cultures wear traditional robes or hats.
- **Holidays and celebrations:** Different cultures celebrate various holidays and festivals that are significant to their beliefs, history, and traditions. For instance, the Lunar New Year is a major holiday celebrated across Asia and many other parts of the world. Recognizing its importance, New York State has officially declared the Lunar New Year a public school holiday through legislative approval (New York State, 2023).
- **Religious practices:** Religion plays a vital role in many cultures, and different religions have their own rituals and practices. For example, Muslims are expected to pray five times a day facing Mecca, while Hindus perform puja ceremonies and offer food and flowers to their deities.

Social Organization

Social organization, or how societies are structured and organized, influences culture, from the distribution of power and resources to the values and beliefs transmitted through education.

Here are a few ways in which social organization can influence culture:

- **Power structures:** The distribution of power and authority in a society can impact cultural practices. For example, in societies where power is concentrated in the hands of a few, cultural practices may reflect and reinforce this power dynamic. Similarly, cultural practices may reflect a more egalitarian ethos in societies where power is more broadly distributed.
- **Social hierarchies:** Whether and how social groups are organized and ranked in a society can also shape cultural practices. For example, in societies with rigid caste systems or class hierarchies, cultural practices may reflect and reinforce these social distinctions. In societies with more fluid social hierarchies, cultural practices may be more diverse and flexible.
- **Economic systems:** How resources are produced, distributed, and consumed in a society influences cultural practices. For example, cultural practices may be more individualistic and consumer-oriented in societies with advanced capitalist economies. In contrast, cultural practices in societies with more collectivist or communal economic systems may focus more on community and shared resources.
- **Education:** Attitudes regarding education can shape cultural practices. For example, in societies where education is valued and accessible, cultural practices may emphasize learning and intellectual pursuits.

21.3 The Role of Culture in Shaping Health Beliefs and Practices

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 21.3.1 Explain the cultural significance of health.
- 21.3.2 Assess how culture influences health.
- 21.3.3 Describe how the cultural environment informs cultural development.

The World Health Organization (WHO) introduced the modern understanding of health as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity” in its constitution in 1948 (Svalastog et al., 2017). In 1986, the Ottawa Charter, signed at the First International Conference on Health Promotion, proposed that health is created in the context of everyday life and environment, where people live, love, work, and play. Societies have historically recognized health as not just the absence of disease but a state of internal harmony. Beliefs about how harmony is created and maintained distinctly influence views on the causes and effects of illness, health-seeking behavior, healing practices, coping mechanisms, and treatment modalities. These views influence one’s sense of control over health, illness, and death.

Historical Views of Health Informing Health-Related Belief Systems

During the period known as ancient Greece, which spanned from the beginning of the Greek Dark Ages around 1200 BCE to the fall of the Western Roman Empire around 600 CE, health was viewed as a harmony between an individual and their surroundings, a unity of both body and soul. Greek philosophy placed great importance on maintaining a healthy body and mind. The Greeks viewed the origin of disease as connected with the geographical and atmospheric environment. In ancient Greece, treatment modalities focused on natural preparations, such as seawater, honey, vinegar, rainwater, and medicinal plants (Kleisiaris et al., 2014).

In East Asian traditions, health results from the unity of body, mind, and spirit, with disease resulting from being off balance. Yin and yang are the underlying principles of Chinese philosophy and medicine. Good health is believed to come from a balance of yin (negative, dark, and feminine) and yang (positive, bright, and masculine) (National Library of Medicine, 2023). The concept of harmony and unity of yin and yang is still practiced today. In some traditional African cultures, health is a balance between the mental, physical, spiritual, and emotional well-being of self, family, and community. Good health includes the ancestors' health, as the ancestors are responsible for keeping the living healthy. Disease is viewed as the result of evil attacks (including spell casting and witchcraft), bad spirits, or punishment by ancestors. Therefore, health is achieved by balancing the visible and invisible worlds (White, 2015). Traditional African practices have influenced views of health and disease globally. For example, Indigenous African beliefs gave rise to the Vodun or Vodou religion (Auguste & Rasmussen, 2019).

Similarly, Native Americans have traditionally believed that physical and spiritual health are connected. To overcome illness, the body and the soul must heal together. Healing ceremonies include prayer, chants, drumming, storytelling, songs, and sacred objects. Concepts of the Spirit, the Creator, and the universe are central to Native beliefs (National Library of Medicine, n.d.-a). The medicine wheel, also called the sacred hoop, has been used by generations of Native American tribes (National Library of Medicine, n.d.-b). The medicine wheel is symbolic of health and the cycles of life. Each tribe has its own interpretation of the medicine wheel, and such wheels continue to be used today. For example, the Medicine Wheel and 12 Steps recovery program is a culturally appropriate 12-step recovery program for Native Americans and Alaska Natives, based on the cycle of life and the four laws of change depicted by the wheel.

CONVERSATIONS ABOUT CULTURE

Medicine Wheel Teaching with Elder Elsey

[Access multimedia content \(<https://openstax.org/books/population-health/pages/21-3-the-role-of-culture-in-shaping-health-beliefs-and-practices>\)](https://openstax.org/books/population-health/pages/21-3-the-role-of-culture-in-shaping-health-beliefs-and-practices)

In this video, Elder Elsey Gauthier speaks about the medicine wheel concept.

Watch the video, and then respond to the following questions.

1. What do the four quadrants of the medicine wheel represent?
2. What is the significance of ceremonies?
3. Describe what it means to be part of the same circle.

The writings of Plato, Aristotle, and Hippocrates influenced the understanding of health in many societies. Plato (429–347 BCE) viewed health as internal harmony and harmony with the physical and social environment. Aristotle associated health with the four basic qualities: hot, cold, wet, and dry. These qualities characterize the four elements, four humors, and four temperaments and serve as the foundations for all notions of balance and homeostasis in ancient Greek medicine. Aristotle emphasized society's role in achieving its harmonious functioning and preserving its members' health (Svalastog et al., 2017). He associated health with the supreme good for humanity, or *eudaimonia*, a philosophical term utilized today as "human flourishing." Hippocrates, widely recognized as the father of medicine, proposed that health depended on the human constitution, proper diet, and exercise. The concept of harmony between the individual, social, and natural environments informed the current holistic health view. Such concepts are reflected in the Hippocratic oath (Kleisiaris et al., 2014).

How people understand health and illness, their beliefs about disease causes, and their strategies to maintain health can vary greatly depending on cultural factors such as beliefs, values, and social norms. For example, in some

cultures, physical and mental health are viewed as interconnected, and holistic approaches to health care are preferred, which may include traditional healing practices, meditation, or herbal remedies. In other cultures, medical treatments may be more focused on addressing specific symptoms, rather than considering the overall health and well-being of the individual.

The Cultural Environment

An individual's **cultural environment** refers to the social, economic, political, and historical factors that shape their experiences and beliefs in a particular culture. This includes the language they speak, the values they hold, the traditions they follow, and the cultural practices they engage in. The cultural environment also includes a culture's social and institutional structures, such as family dynamics, religious institutions, and political systems. The cultural environment can be defined as ecological systems at various levels: microsystems, mesosystems, exosystems, macrosystems, and chronosystems.

The microsystem level consists of the immediate environment in which an individual interacts, including family, friends, and other close relationships. Cultural factors at this level may include family traditions and beliefs, cultural values, and customs related to health and wellness.

The mesosystem level refers to the interactions between different microsystems. For example, at the micro level, family organization influences routine practices essential to psychological health and well-being. Family rituals foster a sense of belonging and personal identity (Fiese et al., 2002). Sharing meals can be an essential family ritual that helps create a sense of togetherness and belonging. Mealtime rituals such as saying grace or having a family member cook a particular dish can be meaningful and reinforce family traditions. Community-level networks promote an individual's and family's physical, psychological, social, and spiritual well-being ([Figure 21.4](#)).

Social organizations can affect how community members interrelate, cooperate, and support one another and influence expectations of support norms and social controls that regulate behavior and interaction patterns (Mancini & Bowen, 2013). Cultural factors at this level may include communication styles, expectations around health care, and cultural beliefs related to health and illness.

FIGURE 21.4 The mesosystem level includes community gatherings, such as this Thanksgiving dinner, which was shared by over 900 members of the Presidio of Monterey military community in California. (credit: "Thanksgiving 2015" by Catherine Caruso/Presidio of Monterey Public Affairs/Flickr, Public Domain)

The exosystem level refers to the external systems and institutions that influence an individual's life, such as the health care system, educational system, and media. Cultural factors at this level may include access to culturally appropriate health care, cultural stereotypes, and media portrayals of health and wellness.

The macrosystem level refers to the broader cultural context in which an individual lives, including societal beliefs, values, and norms. Macrosystems can influence access to resources, including health care. For example, immigration policies may make it difficult for migrant workers and immigrants to seek care due to fear of deportation (Toney et al., 2022). In the United States, immigrants are only eligible to receive benefits or have coverage after being “qualified,” frequently termed a waiting period. In addition, to qualify for Medicaid and the Children’s Health Insurance Program (CHIP), a lawful permanent resident (LPR), also known as a green card holder, must have at least 5 years of residence in the United States (Turner, 2023). See [Caring for Vulnerable Populations and Communities](#) for more information. Cultural factors at this level may include cultural attitudes toward health and wellness, cultural norms related to health behaviors, and policies and laws related to health care access.

The chronosystem level refers to the influence of time and history on an individual’s cultural experiences, including generational and historical changes in cultural beliefs and practices related to health and wellness.

The cultural environment shapes an individual’s perception of the world and influences behavior, including health behavior. It influences perceptions of health, illness, and death; coping mechanisms; and the experience and expression of illness and pain (Agency for Healthcare Research and Quality, 2020).

Cultural Beliefs and Practices Related to Health and Illness

Different cultures have unique beliefs and practices regarding health, illness, and healing, which can influence how individuals approach and manage their health. Health beliefs influence how people think and feel about their health and health problems, when and from whom they seek health care, how they respond to health care interventions, and how well they adhere to treatment (Swihart et al., 2023). For example, in some cultures, people believe that talking about a possible poor health outcome will cause that outcome to occur.

Death and Dying

Different cultures have unique beliefs and practices regarding death, mourning, and the afterlife, which can influence how individuals approach the end of life. In some cultures, mourning may involve specific rituals or customs, such as wearing specific clothing, preparing the deceased, or observing specified periods of mourning. In other cultures, mourning may be less formalized or structured (Giger & Haddad, 2021).

CONVERSATIONS ABOUT CULTURE

Death and Dying: Cultural and Religious Perspectives

[Access multimedia content \(<https://openstax.org/books/population-health/pages/21-3-the-role-of-culture-in-shaping-health-beliefs-and-practices>\)](https://openstax.org/books/population-health/pages/21-3-the-role-of-culture-in-shaping-health-beliefs-and-practices)

This video delves into death, exploring the concept and how cultural and religious perspectives shape our understanding of it.

Watch the video, and then respond to the following questions.

1. How do different cultures conceptualize death, and in what ways do these conceptualizations impact individuals’ views on end of life, readiness to die, and funeral rituals?
2. How does death anxiety manifest across various cultures, and in your opinion, do cultural factors contribute to or alleviate this anxiety?
3. How do different religious beliefs influence funeral practices and rituals in the context of death?
4. Select an example of a funeral ritual from the video and describe how it reflects cultural values and beliefs.

Coping Mechanisms

Coping mechanisms are the strategies and behaviors that individuals use to manage stress and difficult situations. Various cultures have unique coping mechanisms that reflect their values, beliefs, and practices. For example, some cultures may use spiritual practices, such as prayer or meditation, to cope with stress or illness. Others may rely on social support networks like family or community members (Giger & Haddad, 2021).

Perception and Reporting of Illness

Culture can shape how individuals perceive and report symptoms. For example, some cultures may view mental

health symptoms (such as depression) as a sign of weakness or moral failing and may be less likely to seek help or report these symptoms. In contrast, other cultures may prioritize mental health and view seeking help as a sign of strength. Differences also exist regarding the meaning of an illness and whether an illness is “real” or “imagined” (Giger & Haddad, 2021).

Pain and Discomfort

Many cultures have unique beliefs, values, and practices that shape their experiences of pain and discomfort. For example, in some cultures, it may be common to downplay or minimize symptoms of illness or pain. This may be due to a cultural belief that expressing vulnerability or weakness is undesirable or that complaining about pain is a sign of ingratitude. In contrast, other cultures may encourage individuals to be vocal about their pain and discomfort to seek help and support from others (Giger & Haddad, 2021).

CONVERSATIONS ABOUT CULTURE

Cultural Influence: Perception of Pain

[Access multimedia content \(<https://openstax.org/books/population-health/pages/21-3-the-role-of-culture-in-shaping-health-beliefs-and-practices>\)](https://openstax.org/books/population-health/pages/21-3-the-role-of-culture-in-shaping-health-beliefs-and-practices)

This video depicts the interaction between a health care provider and Carlos, a postoperative client. It addresses issues associated with making assumptions and emphasizes the importance of listening to the client.

Watch the video, and then respond to the following questions.

1. How does culture influence pain response and expression?
2. Could the physician have responded differently to Carlos’s request? If so, how?
3. How do assumptions regarding drug-seeking behavior impact client care?

21.4 Overview of Cultural Views and Practices

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 21.4.1 Explain how generalizations and stereotypes impact health outcomes.
- 21.4.2 Describe various cultural practices and views of the world.
- 21.4.3 Identify shared cultural beliefs, values, and customs influencing health.
- 21.4.4 Develop care plans that consider the impact of cultural influences on disease management.

Disregarding cultural elements in clinical practice can lead to low-quality or unsafe care, such as perfunctory or inadequate evaluations, errors in diagnosis, unsuitable treatment plans, or noncompliance by clients and families (Johnson-Lafleur et al., 2023).

Developing cultural awareness as to how people acquire certain practices in their cultures and the role that culture plays in forming individual personal identity, worldview, lifestyle, and health beliefs and practices is essential preparation for [Transcultural Nursing](#), which will revisit Giger and Davidhizar’s transcultural model from the perspective of conducting a cultural assessment.

Cultural Generalizations and Stereotyping

Broad observations about a culture’s shared characteristics or patterns are known as cultural generalizations. These generalizations are not necessarily positive or negative and can describe cultural practices, values, or traditions. For instance, it is a cultural generalization to say that family values are highly emphasized in many Asian cultures or that punctuality is highly valued in some European countries. It is important to recognize that these generalizations are tendencies, not universally applicable traits. They can provide insights into the cultural norms of a particular group and promote cultural awareness and sensitivity, but they should be used thoughtfully and cautiously.

On the other hand, stereotyping involves making oversimplified assumptions about individuals or groups based on their cultural backgrounds. It often results from prejudices, biases, or limited knowledge and leads to the unfair characterization of an entire group based on the actions or behaviors of a few individuals. Examples of stereotyping include assuming that all members of a particular ethnicity are good at math or all people of a certain nationality are

loud and aggressive. Stereotyping is damaging and perpetuates harmful biases, leading to discrimination and exclusion of individuals based on their cultural background.

Even though cultural groups may share customs, traditions, and ways of life, there is always diversity and individuality in any culture. Judgments about a particular culture are often based on a limited number of observed characteristics, which can be oversimplified, misrepresented, exaggerated, or distorted. This can lead to false assumptions and stereotyping based on race, gender, religion, or culture, resulting in prejudice, ecological fallacies, and discrimination. As the multicultural population in the United States continues to grow, it is crucial for nurses to recognize and appreciate cultural differences in health care values, beliefs, and customs.

To create a more inclusive and understanding society, it's important to distinguish between cultural generalizations and stereotypes. Nurses should strive to learn and appreciate the uniqueness and diversity within cultures while recognizing that each person has their own beliefs, values, and experiences that may or may not align with cultural generalizations. By promoting cultural competence and avoiding stereotypes, nurses can minimize misunderstandings and negative interactions.

Cultural Practices and Views of the World

How someone views the world, or their worldview, has a big impact on their health and approach to health care. Different societies and cultures have their own beliefs, values, and attitudes toward health and illness, which affect how they behave, seek health care, and interact with the health care system.

These cultural practices and views are shaped by factors like history, society, religion, and the environment. They affect how people communicate, feel about personal space, organize socially, perceive time, control their environment, and form dietary habits. These concepts are part of the transcultural model developed by Giger and Davidhizar, which is introduced in [Transcultural Nursing](#).

As health care providers, nurses must acknowledge and appreciate the impact of cultural factors on health to deliver effective and culturally sensitive care. This requires nurses to embrace cultural diversity and be receptive to diverse perspectives. By doing so, nurses can broaden their understanding of the world and contribute to a more inclusive and harmonious global community. Providing culturally responsive health care promotes trust, enhances communication, increases treatment adherence, and leads to better health outcomes for individuals from diverse cultural backgrounds.

Communication

Culture influences everything from language and nonverbal communication to communication styles and the values and beliefs that underlie communication. Communication is learned, transmitted, universal, and inclusive of human interaction and behavior. Although two individuals may speak the same language, differences can exist in communication patterns and understandings because of cultural orientation. Culture influences linguistic patterns, how feelings are expressed, and the appropriateness of verbal and nonverbal expressions (Giger & Haddad, 2021).

Verbal communication is associated with languages, including vocabulary and grammatical structure (Halliday, 2006). Language is a form of verbal and written communication and a key component of culture, with different cultures having different languages, dialects, and accents. Language affects what one says and how they say it, so cultural language differences have an impact on how people communicate. For example, some cultures may emphasize formality and politeness in their language use, while others may be more blunt and more direct.

In comparison, body language or motion (kinetic behavior) is an example of nonverbal communication. **Nonverbal communication** conveys messages without words. Different cultures may use different nonverbal cues to convey meaning or express emotion. In some cultures, direct eye contact may be seen as a sign of respect and engagement. For example, some Haitian Americans use direct eye contact to gain attention and respect during communication. In comparison, others may see this as disrespectful or confrontational. For example, among some Vietnamese Americans and Native Americans, avoidance of eye contact is a sign of respect. Among other cultures, such as Mexican Americans, looking at and admiring a child without touching them can be viewed as giving the child the "evil eye" (Giger & Haddad, 2021). In Buddhist cultures, the head is considered sacred, as it is the highest part of the body, and patting the head is considered rude, while the feet are considered dirty. [Table 21.2](#) lists examples of

verbal and nonverbal forms of communication.

Verbal Forms of Communication	Nonverbal Forms of Communication
<ul style="list-style-type: none"> • Vocabulary • Grammatical structure • Voice qualities • Intonation • Rhythm • Speed • Pronunciation • Silence 	<ul style="list-style-type: none"> • Touch • Facial expression • Eye movement • Body posture • Hand gestures

TABLE 21.2 Forms of Communication

Different cultures may also have different communication styles, such as whether communication is more direct or indirect or whether emotions are expressed openly or kept hidden. These communication styles can impact how messages are received and interpreted by others.

Cultural values and beliefs can influence what is considered appropriate or acceptable to talk about. For example, in some cultures, it may be considered impolite to criticize others openly or to express strong emotions. In others, it may be seen as necessary for honest communication (Giger & Haddad, 2021).

Understanding these cultural differences is essential for effective communication across cultures. Cultural practices affect how people interact with each other. For example, some Alaska Natives seldom disagree publicly with others and may nod yes to be polite, even if not in agreement. In some cultures, it is customary to bow or shake hands when greeting someone, while in others, people may kiss each other on the cheek or give a hug. Among Orthodox Jews and Hasidim, touching, particularly from members of a different sex, is offensive (Giger & Haddad, 2021).

Nurses must be aware of a client's preferences and practices to avoid miscommunication. Nurses should monitor body language and clients closely to detect meaning.

Space

Space is the setting where communication occurs and includes the space surrounding a person's body and the objects in the space. An individual's comfort level is related to inner and outer personal space, which can vary from culture to culture.

Human perception of social and personal space is culturally bound. For example, in Western culture, space is viewed as having four dimensions, or zones: the intimate zone (0 to 18 inches), the personal zone (18 inches to 3 feet), the social zone (3 to 6 feet), and the public zone (6 feet or more) ([Figure 21.5](#)) (Hall, 1976). Each dimension or zone has a different purpose. For example, the intimate dimension is associated with comforting, protecting, and counseling. The **personal dimension** is best illustrated as the "friend zone," in which communication with less intimate but still familiar companions occurs. Touch is an essential feature of both the intimate and personal dimensions. The **social dimension** is considered the impersonal business zone and is associated with people working together. Sensory involvement, such as touch, is generally less intense in the social dimension (Giger & Haddad, 2021).

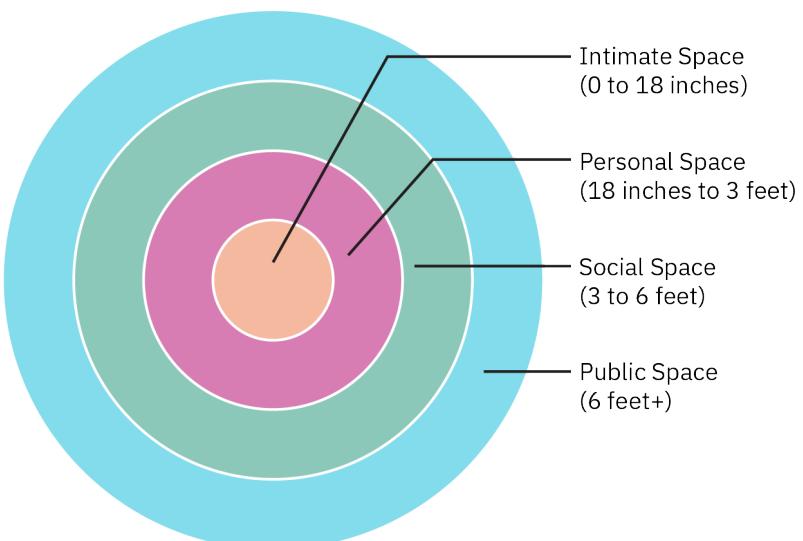

FIGURE 21.5 Western culture has four dimensions of physical distance between people, depending on the situation. Other cultures view personal space differently. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Color can have symbolic cultural implications. For example, in some Asian cultures, white is associated with a funeral, while in some African cultures, red symbolizes death (Giger & Haddad, 2021). The color red may be associated with luck, love, and prosperity in some cultures, while in others it may be seen as a symbol of danger or warning.

Cultural traditions and religious beliefs can also influence color choices. For example, in some African cultures, bright, bold colors are often used in clothing and textiles, reflecting these regions' vibrant and colorful environments. In Christianity, purple is associated with Lent and is often used in liturgical decorations during this season.

Social Organization

As discussed in [Cultural Groups and the Formation of a Cultural Identity](#), social organization refers to the ways in which groups organize themselves. The social organization of societies influences culture, and the social organization of a cultural group, including family structure and organization, religious values and beliefs, and role assignment, is a part of that group's culture (Giger & Davidhizar, 2002).

The family is discussed in more detail in [Caring for Families](#). Family structure and organization are culturally bound, which means that culture affects the attitudes, practices, or behaviors of the family.

Family structure and organization and religious values and beliefs inform gender norms and role assignment in group settings. Children are socialized into gender roles. As a social construct, gender roles vary from society to society and can change over time (World Health Organization, 2023, para. 1). Additionally, gender roles are generally associated with a social hierarchy that gives different statuses to different group members. Cultural expectations around gender roles can also impact family organization and function.

Different cultures may have different expectations for family structure, such as the number of generations living together or the role of extended family members. In many cultures, it is common for multiple generations to live together in a single household, while in others, the nuclear family is emphasized.

Often, decisions about health care are made by the family rather than solely by the individual. Family organization can impact how health care decisions are made and who participates in decision-making. Family members can also play a role in communication with health care providers. In cultures where family members are heavily involved in health care decision-making, they may be more likely to accompany the individual to medical appointments and participate in discussions with health care providers.

Time Perception

Cross-cultural research indicates that there are two types of time: clock time, where an external timepiece dictates action and events, and social time, which is governed by the flow of activity or when "the time is right." The view of

social time vs. clock time differs globally (Begic & Mercer, 2017). For example (Giger & Haddad, 2021):

- Khasi people, an ethnic group in the state of Meghalaya in northeastern India, have an 8-day week.
- Some Amish people keep *slow time*, in which they set clocks a half hour ahead when others convert from daylight saving time to standard time.
- Many people of Asian origin view time as flexible.

Perspectives on time may be oriented to past, present, or future (Begic & Mercer, 2017). Here are a few examples of how different cultures may perceive time (Giger & Haddad, 2021):

- Past orientation: Some cultures place a strong emphasis on the past and may view time as cyclical or circular rather than linear. These cultures may prioritize traditions and rituals passed down through generations and may view the present and future as interconnected with the past.
- Present orientation vs. future orientation: Some cultures may have a more present-oriented perspective, focusing on enjoying the moment and responding to immediate needs. Other cultures have a strong focus on planning for the future and investing time and resources in long-term goals.

Cultures may also be influenced by biological rhythms, such as the cycle of day and night. Some cultures may emphasize waking and sleeping at particular times or may have cultural practices tied to natural cycles, such as farming or hunting.

Environmental Control

Environmental control describes an individual's control over nature and environmental factors. Views of environmental control affect illness and health-seeking behaviors, which are influenced by one's sense of locus of control. *Locus of control* (Rotter, 1966) refers to an individual's beliefs about the extent of their control over the environment and what happens to them. Locus of control can be external or internal:

- Internal locus of control:
 - Individuals believe that they are responsible for their success/outcomes.
 - Individuals are more likely to take independent action to manage disease symptoms.
- External locus of control:
 - Individuals believe that external forces, like luck or fate, determine outcomes.
 - Individuals are more likely to depend on others to manage disease symptoms.

Whether the cause of illness is believed to be natural or unnatural further influences health behavior. **Natural events** are considered an inherent aspect of the world, resulting from causes such as environmental sanitation, personal hygiene, poverty, or biological or psychological factors. They are perceived to have some degree of predictability and to be subject to some element of control (Kahissay et al., 2017). In comparison, **unnatural events** are viewed as the consequence of disharmony in nature. They are not predictable and are beyond human control (Giger & Haddad, 2021). For example, some cultures may attribute illness to supernatural causes, such as curses or evil spirits, and may use spiritual or religious practices to address these causes (Kahissay et al., 2017).

An individual's belief about whether an illness has natural or unnatural causes affects the types of cures/treatments they may seek. Alternative therapies are practices intended to promote health that are not represented in traditional Western/modern medical treatment or conventional medical practices. They often represent traditional health practices that are customary to various cultural groups. These therapies can be categorized as energy-based, biologically based, manipulative or body-based, and mind-body-based. These alternative therapies are often embedded in the folk medicine belief system. In many cultures and faiths, alternative therapies and religious practices include blessings from spiritual leaders, healing power, and the use of objects in healing ceremonies.

Folk and traditional beliefs are shaped by culture. For example, traditional Chinese medicine includes practices such as acupuncture, tai chi, moxibustion (burning of herbal leaves on or near the body), cupping (using warmed glass jars to create suction on specific points on the body), and use of herbalists ([Figure 21.6](#)).

FIGURE 21.6 Cupping is an ancient, holistic treatment for various diseases traced back to early Egyptian and Chinese medical practice. (credit: "Cupping" by Alanna Ralph/Flickr, CC BY 2.0)

The rootwork system is a traditional African American folk practice that involves using herbs, roots, and other natural materials to address various health and spiritual concerns. This practice has its roots in African spiritual traditions and was brought to the United States during the period of enslavement of Africans. Rootwork is a holistic practice that encompasses physical, mental, and spiritual health (Mathews, 1987).

Traditional practitioners who deliver care include healers, shamans, and priests. For example, among some Latin Americans, “treatment comes primarily through a variety of healers that include the *curandero* (healer who uses prayer and artifacts), *yerbero* (herbalist), *espiritista* (practitioner of *espiritismo*, a religious [tradition] concerned with communication with spirits and the purification of the soul through moral behavior), and *santero* (practitioner of *Santería*, a religious [tradition] concerned with teaching people how to control or placate the supernatural)” (Giger & Haddad, 2021, p. 110).

A shaman serves as a mediator between the supernatural and the individual. In comparison, the medicine man or woman utilizes traditional techniques to cure disease. Priests perform rituals and ministerial functions as part of particular religions.

Dietary Practices and Nutritional Preferences

The relationship between food and culture is complex and multifaceted. Food is not only a source of nourishment; it also has social, symbolic, and cultural meanings. Food-related traditions and rituals are an essential aspect of many cultures. Holidays and festivals often involve traditional foods and special meals, which can be a way of connecting with one’s cultural heritage and history. Food can also mark important life events such as weddings, funerals, and religious ceremonies.

Cultural practices and beliefs influence what foods are acceptable or desirable and how food is prepared and consumed. Certain foods may be considered taboo or forbidden in some cultures, while in others, they are celebrated and eaten in large quantities. Food can also express cultural or community identity and belonging.

A range of factors, including geography, climate, religion, history, and social norms, shape cultural dietary practices. These practices can vary widely across different regions and communities and significantly impact health. They can also affect health behaviors. For instance, cultural norms may dictate specific dietary restrictions or preferences. These factors can influence the prevalence of obesity, diabetes, and cardiovascular disease.

Some cultures believe that certain nonfood items have medicinal or healing properties. For example, some African and Caribbean cultures believe that consuming clay or dirt (known as *geophagia*) aids digestion, prevents nausea

during pregnancy, and improves overall health (Madziva & Chinouya, 2020). In other cultures, consuming nonfood items such as charcoal, chalk, or ice may be seen as a remedy for various ailments (Sruthi, 2023).

Dietary practices can affect dietary needs and create mineral deficiencies. For example, some Native Americans consume inadequate amounts of protein, calcium, and vitamins A and C. This is due to various factors, including limited access to healthy foods, cultural dietary practices, and historical factors such as the forced removal of Indigenous peoples from their traditional lands and the imposition of Western diets. Traditional Native American diets were often based on locally sourced foods rich in protein, fiber, and nutrients.

Cultural dietary practices are complex and multifaceted. The nurse should approach cultural dietary practices with respect and cultural sensitivity and work with clients to understand their unique dietary needs and preferences.

The Role of Culture in Disease Management

The role of culture in disease management is significant and multifaceted. Culture influences how individuals perceive, experience, and respond to health, illness, and treatment. The box below provides an example of the role culture plays in shaping the health of a South Asian community. Understanding cultural context is crucial for health care professionals to provide effective, client-centered disease management.

THE ROLE OF CULTURE IN SHAPING HEALTH BELIEFS AND PRACTICES IN THE MANAGEMENT OF DIABETES

By 2050, around 134 million people in South Asia, including those in India, Pakistan, Bangladesh, and Sri Lanka, will be affected by type 2 diabetes (Hills et al., 2018). Even after considering age, sex, and body mass index (BMI), South Asian immigrants in the United States have a much higher rate of type 2 diabetes (27 percent) than non-Hispanic White individuals in the United States (8 percent) (Hills et al., 2018). When helping individuals of South Asian descent manage diabetes, nurses should be aware of the following culturally influenced health beliefs, behaviors, and practices that may contribute to this difference:

- Diet and nutrition: South Asian cuisine often includes staple foods like rice, chapati, and lentils, which can be high in carbohydrates. Traditional cooking methods may involve frying or using ghee (clarified butter), which can contribute to a higher intake of unhealthy fats. Cultural preferences for certain foods, spices, and flavors can influence dietary choices, making it essential to address culturally appropriate dietary modifications that balance taste and health needs.
- Cultural perceptions of health: Cultural beliefs and norms surrounding health and illness can impact diabetes management. Traditional wellness concepts and ideas about the causes and treatment of diseases may differ from Western biomedical perspectives. Understanding these beliefs can help health care professionals tailor interventions and promote health literacy.
- Family and social support: South Asian communities often prioritize strong family ties and social networks. In diabetes management, family support can be crucial for adopting and sustaining lifestyle changes. Involving family members in education sessions, meal planning, and exercise routines can enhance adherence and overall success in managing the condition.
- Language and communication: Language barriers can hinder effective communication between health care providers and South Asian clients. Cultural nuances and expressions related to diabetes management may not have direct translations, impacting the delivery and understanding of medical advice. Culturally responsive health care providers or interpreters who understand South Asian cultural contexts can help bridge these communication gaps.
- Stigma and mental health: Diabetes can carry a stigma in some South Asian communities, leading to emotional and psychological challenges for individuals with the condition. Fear of judgment or discrimination may discourage clients from seeking appropriate health care or openly discussing diabetes-related concerns. Addressing mental health aspects, providing psychosocial support, and creating safe spaces for open dialogue can help individuals overcome stigma.

(See Adhikari & Mishra, 2019; Subhan et al., 2023.)

Culture plays a role in disease management, influencing how individuals perceive, experience, and respond to health

and illness. Nurses must approach disease management with cultural sensitivity, humility, and respect to provide client-centered care and improve health outcomes for all individuals. [Figure 21.7](#) illustrates how aspects of culture can affect health behaviors and treatment for a client with type 2 diabetes.

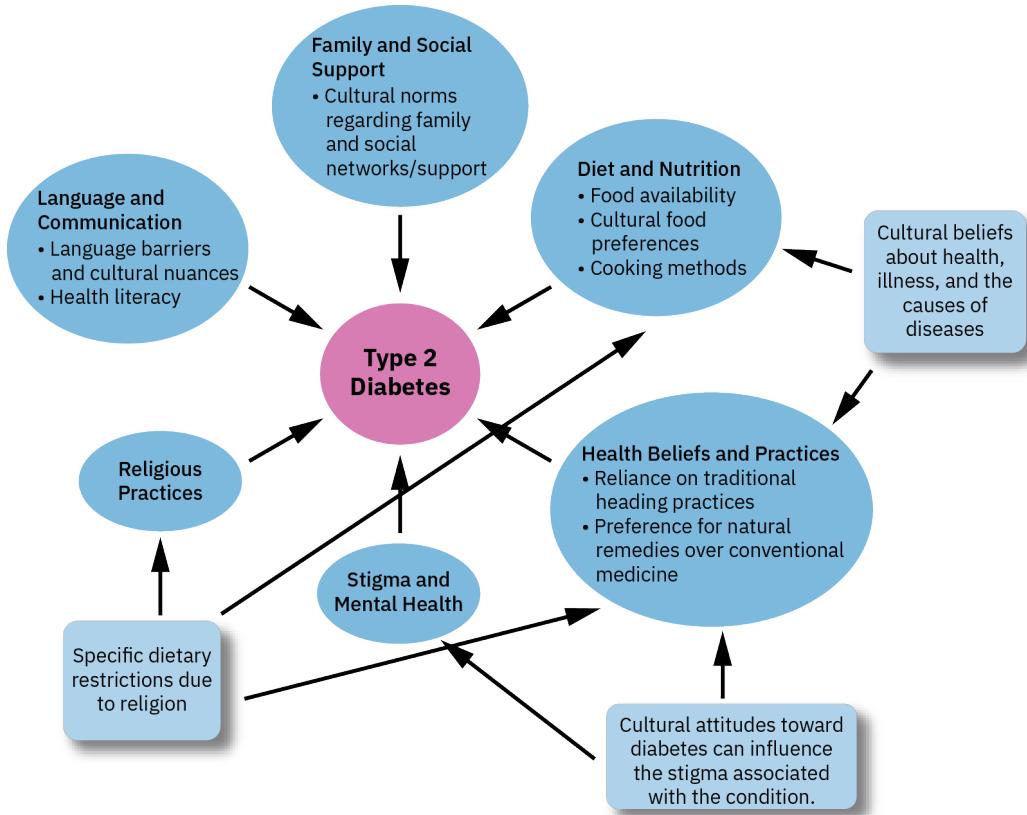

FIGURE 21.7 This web of causation shows the many cultural factors that affect client health behaviors and that should inform treatment plans for individual clients. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Understanding and incorporating cultural beliefs, values, and practices into care plans demonstrates cultural competence. This enhances the nurse's ability to deliver practical, client-centered care that respects and addresses the client's cultural background. Clients are more likely to adhere to treatment plans that align with their cultural beliefs and practices. By considering cultural factors, nurses can design care plans that are more acceptable and meaningful to clients, leading to better treatment adherence and improved health outcomes.

21.5 Culture Matters in Addressing Health Inequalities

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 21.5.1 Recognize how culture influences health outcomes.
- 21.5.2 Identify questions nurses can ask to promote cultural understanding.
- 21.5.3 Describe culture's role in shaping health beliefs and practices and the implications for health outcomes.

Minority populations in the United States face persistent racial disparities resulting from systematic inequality. Factors such as poverty; lack of access to healthy food, safe housing, and quality health care; discrimination; and environmental toxins can contribute to the development of chronic diseases such as diabetes, heart disease, and asthma, as well as mental health disorders. See [Structural Racism and Systemic Inequities](#) for more information.

Disparities in health outcomes have significant implications for individuals, families, and communities. They can lead to reduced quality of life, increased health care costs, and decreased productivity and economic opportunities. In addition, they can perpetuate cycles of poverty and disadvantage as individuals and communities struggle to overcome the burden of poor health.

Social Determinants of Health and Culture

As discussed in [Social Determinants Affecting Health Outcomes](#), social determinants of health (SDOH) are the conditions in which people are born, grow, live, work, and age. This definition includes socioeconomic status, education, immigration status, language, neighborhood and physical environment, employment, social support networks, and access to health care. These determinants are shaped by social, economic, and political forces and can profoundly impact health outcomes.

Culture is also an SDOH because it can shape health beliefs, behaviors, and practices. As discussed previously, cultural beliefs and values can influence a person's decision to seek health care, adherence to treatment plans, and perceptions of health and illness. For example, cultural beliefs about mental health may influence a person's willingness to seek treatment for depression or anxiety. Ultimately, cultural and social determinants impact an individual's health and well-being.

Furthermore, cultural factors can intersect with other social determinants of health. For instance, individuals from racial and ethnic minority populations may experience disparities in health care access and outcomes due to social and economic factors such as poverty, limited education, and discrimination. These disparities can be exacerbated by cultural factors such as language barriers, mistrust of the health care system, and traditional health practices.

Legal scholar Kimberlé Crenshaw coined the term **intersectionality** in 1989 to describe the interconnectedness of social identities, such as race, gender, sexual orientation, and socioeconomic status, and how they overlap and intersect to create unique experiences of privilege or oppression. These experiences cannot be understood by looking at each identity in isolation. This framework is particularly relevant when considering health disparities, as people of color, women, LGBTQ+ individuals, and those with lower socioeconomic status may experience compounding disadvantages that impact their health outcomes. The box in the previous section examined the role culture plays in diabetes management for South Asian communities. The box below considers how SDOH have influenced diabetes management among this population.

INFLUENCE OF SOCIAL DETERMINANTS OF HEALTH IN DIABETES MANAGEMENT OF SOUTH ASIAN IMMIGRANTS

Various social determinants of health can significantly influence the management of diabetes in South Asian immigrants. These determinants include language barriers, access to resources, health literacy, education, discrimination, and stress.

- Language and cultural barriers: Language differences can create communication obstacles between health care providers and South Asian immigrants, hindering their ability to comprehend diabetes management instructions, treatment plans, and access to suitable resources. Additionally, cultural beliefs, norms, and practices can impact diabetes management decisions and adherence to treatment recommendations. South Asian immigrants tend to place great importance on family (Bhandari & Titzmann, 2017); therefore, involving family members in self-management is crucial (Baig et al., 2015).
- Health literacy and education: Limited health literacy and lack of diabetes education materials in native languages can hinder South Asian immigrants' ability to self-manage diabetes. Addressing health literacy gaps and providing culturally appropriate educational resources are crucial for diabetes management (Estacio et al., 2015; Min et al., 2022).
- Discrimination and acculturation stress: South Asian immigrants may face discrimination, racism, and acculturation stress, which can contribute to chronic stress levels and impact diabetes management. Discrimination in health care settings can lead to mistrust and reluctance to seek necessary care. Acculturative stress can have a negative impact on mental health when individuals attempt to integrate host country customs into their own culture. This stress can manifest in various forms, including intergenerational conflict, discrimination, and depression (Karasz et al., 2019).

To effectively manage diabetes—or any other health issue—in South Asian immigrants, nurses must consider these factors; provide culturally sensitive health care services, language access, and health education; and address the effects of cultural and intersectional discrimination. Collaborating with South Asian immigrants to

address their specific needs and overcome barriers is key to effective diabetes management.

Understanding and addressing the cultural and social determinants of health is essential to promoting health equity and reducing health disparities. By recognizing the influence of culture on health outcomes and working to reduce barriers to care, health care providers can improve health outcomes for all individuals and communities.

Client-Centered Care

Cultural misunderstandings can affect the nurse's ability to assist clients in achieving optimal health outcomes. Nurses and other health care providers caring for a client whose native culture is different from their own may make assumptions about the client's intelligence and perceive them as irresponsible or disinterested in their health due to a lack of understanding of cultural beliefs and values (Dowling, 2002). As discussed at the beginning of this chapter, nurses and other health care providers must avoid stereotyping based on religious or cultural background as a measure of client safety. Nurses must recognize that each person has a cultural identity (Agency for Healthcare Research and Quality, 2020). Cultural misunderstandings can be avoided by asking clients to share their health beliefs and customs.

According to the Agency for Healthcare Research and Quality (2020), nurses and other health care providers should be prepared to respectfully ask clients about their culture and beliefs in the context of providing care. Centering the client's view and experience builds trust and can help ensure the nurse provides respectful, appropriate care. For example, a nurse might ask a client the following:

- Do you have any dietary restrictions we should consider as we develop a food plan to address your health concerns?
- Some people like to know all the details about their illness, while others prefer to know only what is most important. How much do you want to know, and is there anyone else you would like me to talk to about your condition?
- What do you call your illness, and what do you think caused it?
- Do any traditional healers advise you about your health?

Health care professionals, particularly nurses, have an ethical responsibility to fully understand how culture shapes health beliefs and practices and influences health outcomes. Nurses must recognize that a person's culture is a crucial aspect of their identity. Nurses must be capable of managing cultural differences in beliefs and practices to promote a client-centered relationship. These topics will be examined further in [Transcultural Nursing](#) and [Culturally and Linguistically Responsive Nursing Care](#).

Chapter Summary

21.1 Race, Ethnicity, Culture, and Nationality

Race, ethnicity, culture, and nationality are related concepts that are often used interchangeably but have distinct meanings. A person's race and ethnicity can shape their cultural experiences and traditions, while their nationality can influence their legal status and access to resources. Understanding the complexities and nuances of these concepts is important for promoting diversity, equity, and inclusion in society.

21.2 Cultural Groups and Formation of a Cultural Identity

Culture is a broad term that refers to the shared beliefs, values, customs, behaviors, and artifacts that characterize a particular group or society. Culture encompasses many distinct aspects of the human experience, including language, religion, ceremonies, celebrations, art, music, food, clothing, social habits, and more. It is transmitted from generation to generation through socialization, education, and other means of communication, and it shapes how an individual thinks, behaves, and interacts with the world. Culture can be specific to a particular region, country, or ethnic group or shared across national and ethnic boundaries, and it evolves over time. Nurses must understand and appreciate cultural differences to provide client-centered care.

21.3 The Role of Culture in Shaping Health Beliefs and Practices

The definition of *health* has evolved over time and varies across cultures depending on cultural beliefs, values, and practices. Among many cultures, the causes of illness are believed to include both physical and spiritual factors. For example, some cultures attribute illness to a lack of spiritual balance, while

others see it as the result of social or emotional stressors. Understanding an individual's perception of health can help nurses develop plans of care that are appropriate and effective for the individual client.

21.4 Overview of Cultural Views and Practices

Culture plays a significant role in shaping health beliefs and practices. Health is viewed and experienced differently across cultures, and beliefs about appropriate treatments for conditions and diseases can vary widely. Cultural beliefs can influence health behaviors and decision-making, such as seeking medical care or adhering to treatment plans. By understanding and respecting cultural beliefs and practices related to health, nurses can provide more effective client-centered care.

21.5 Culture Matters in Addressing Health Inequalities

Culture is a social determinant of health because cultural factors affect an individual's health and well-being. These cultural factors include beliefs, values, traditions, and social norms, which can all influence an individual's health behaviors and outcomes.

Intersectionality acknowledges that individuals may experience multiple forms of discrimination or privilege based on their various identities and that these experiences cannot be understood by looking at each identity in isolation. In health care, an intersectional approach can help nurses address health disparities by recognizing and addressing the complex and intersecting factors that contribute to health outcomes. Nurses have a primary responsibility to understand the role culture plays in shaping not only health beliefs and practices but also implications for health outcomes.

Key Terms

cultural environment the social, economic, political, and historical factors that shape an individual's experiences and beliefs in a particular culture

cultural group a group formed through the unification of shared activities and values

cultural pluralism a state of having one dominant culture in which all minority groups participate fully

culture a historically transmitted pattern of meaning based upon learned and shared values, beliefs, attitudes, and customs that involves patterned responses to behavior and distinguishes the members of one group of people from others

diversity the representation and relative size of different groups, such as racial and ethnic groups, in a population

enculturation the social acquisition of cultural patterns of behavior

environmental control an individual's control over nature and environmental factors, views of which affect illness and health-seeking behaviors

ethnicity inherited affiliation with a group that is defined by shared cultural traits, such as language, religion, nationality, history, or other cultural factors

heterogeneous society a society that is made up of

multiple cultures	companions occurs
homogeneous society a society that is primarily made up of only one dominant culture	race a societal construct commonly defined by physical characteristics, such as bone structure, skin, hair, or eye color, as well as social factors and cultural backgrounds; not biologically predetermined
intersectionality the interconnectedness of social identities, such as race, gender, sexual orientation, and socioeconomic status, and how they overlap and intersect to create unique experiences of privilege or oppression	social dimension the impersonal business zone, associated with people who are working together
multiculturalism the coexistence of diverse religious, ethnic, or cultural groups in a society while adhering to the same rules, with no single culture holding more importance than the others	space the setting where communication takes place; includes the space surrounding a person's body and the objects in that space
nationality an individual's country of citizenship	subculture a smaller group in a cultural group that shares distinguishing characteristics that may identify with aspects of its larger parent culture
natural events events that are considered an inherent aspect of the world and are perceived to have some degree of predictability and be subject to some element of control	unnatural events viewed as the consequence of disharmony in nature and are often associated with forces of evil; not predictable and beyond human control
nonverbal communication the conveying of messages without words	verbal communication the conveying of messages through the use of words
personal dimension the "friend zone," in which communication with less intimate but still familiar	

Review Questions

1. Which action should the nurse take to meet the nutritional needs of a Jewish client?
 - a. Order a kosher meal for the client.
 - b. Ask the client about their dietary preferences.
 - c. Have the meal served on paper plates.
 - d. Consult with the dietitian.

2. The nurse is providing care to a client who follows a holistic medicine approach to health care. Which aspect of care should the nurse anticipate when developing a plan of care for this client?
 - a. Decisions are guided by fate.
 - b. Treatment should be aggressive.
 - c. Physical and mental needs should be balanced.
 - d. Statistical data will guide care.

3. A nurse who works with clients from different cultures wants to understand the invisible elements of culture. Which is an example of an invisible cultural element?
 - a. Notions of time
 - b. Clothing worn
 - c. Traditional foods
 - d. Language spoken

4. Which action should the nurse take to communicate with a client from a culture that is different from their own?
 - a. Use touch as a therapeutic tool.
 - b. Sit close to the client.
 - c. Pay attention to the client's nonverbal cues.
 - d. Maintain eye contact even if the client does not.

5. Which level of the cultural environment is being assessed when the nurse asks a client about family rituals and traditions?
 - a. Microsystem

- b. Mesosystem
 - c. Exosystem
 - d. Macrosystem
6. The nurse is discussing the importance of regular exercise with a client diagnosed with hypertension. The client responds, "I just don't have the time for exercise." The nurse determines that the client has which time orientation?
- a. Past time orientation
 - b. Present time orientation
 - c. Future time orientation
 - d. Lack of time orientation
7. The nurse is caring for a client who is reluctant to take pain medication, fearing that if they do so others will see them as weak. Which of the following statements best describes how the nurse should initially respond?
- a. The nurse should acknowledge the client's cultural influences and listen to the client's concerns.
 - b. The nurse should provide additional education on the benefits of taking the medication.
 - c. The nurse should encourage the client to prioritize their personal health and well-being.
 - d. The nurse should encourage the client to prioritize their physical needs over what others may think.
8. The nurse is assessing a migrant worker who has abdominal pain. Which of the following questions should the nurse include as part of a culturally sensitive assessment?
- a. "Have you used any over-the-counter medications to treat the pain?"
 - b. "Have you taken any medications or herbs or used any home treatments for the pain?"
 - c. "Why do you think you are having this problem?"
 - d. "What does your manager think about your illness?"
9. The nurse is discussing risk factor modification with a client diagnosed with hypertension. Which client statement does the nurse recognize as representing an external locus of control?
- a. "High blood pressure causes blood vessel damage."
 - b. "My fate has already been determined."
 - c. "Eating right can improve my health."
 - d. "I am motivated to make lifestyle changes."
10. The nurse anticipates that a client from a culture that values collectivism will utilize which concept when making a health care decision?
- a. Making an independent decision
 - b. Seeking input from the community
 - c. Prioritizing mental health needs
 - d. Considering all available options

CHAPTER 22

Transcultural Nursing

FIGURE 22.1 The focus of transcultural nursing is to provide culturally sensitive and competent care to individuals from diverse cultural backgrounds. This U.S. Navy nurse takes care to explain what she is doing in terms that her client, a child and resident of El Salvador, can understand. (credit: modification of work “ACAJUTLA, El Salvador (July 31, 2007) - Lt. Megan Zeller, an intensive care unit nurse, checks the vital signs of patient” by Mass Communication Specialist 3rd Class Kelly E. Barnes/U.S. Navy/Wikimedia Commons, Public Domain)

CHAPTER OUTLINE

- 22.1 What Is Transcultural Nursing?
 - 22.2 Cultural Models
 - 22.3 Cultural Assessment
-

INTRODUCTION Maria is a nurse assigned to care for Wang Xiu, a client who recently emigrated from China to the United States and speaks English as a second language. Maria approaches the client with respect and curiosity, eager to learn more about her cultural background. Wang Xiu shares that she follows traditional Chinese medicine and prefers herbal remedies over Western medications. Maria listens attentively and asks follow-up questions to better understand the client’s cultural beliefs. She also documents her findings in the client’s medical record to ensure that other health care providers on the team will provide culturally sensitive care in the future.

Throughout Wang Xiu’s stay, Maria incorporates the client’s cultural needs into her care plan. She works with the health care team to ensure her client receives herbal remedies and traditional Chinese foods that align with her cultural beliefs. Thanks to Maria’s cultural assessment and sensitivity, Wang Xiu feels respected and valued as an individual with unique cultural needs. Maria’s work helps to bridge cultural gaps in health care and ensures that Wang Xiu receives the best possible care.

Nurses like Maria need to know about transcultural nursing to provide culturally sensitive care to clients from diverse backgrounds, whether, like Wang Xiu, they may have recently immigrated to the United States or have cultural identities that are different from those of the nurse. This chapter discusses transcultural nursing, the

models that guide care, and how to perform a cultural assessment.

22.1 What Is Transcultural Nursing?

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 22.1.1 Define transcultural nursing.
- 22.1.2 Discuss the importance of transcultural models and frameworks to nursing practice.

Transcultural nursing is a concept that has emerged in response to the increasing diversity of clients in health care settings. It is a framework that seeks to provide **culturally sensitive care** to individuals from diverse cultural backgrounds. Transcultural nursing recognizes that culture significantly shapes an individual's health beliefs, behaviors, and practices. Therefore, it emphasizes the importance of understanding and respecting cultural differences in health care delivery.

Transcultural nursing has its roots in the mid-1950s, when nursing pioneer Hildegard Peplau began considering the importance of culture as a variable affecting mental health (Hagerty et al., 2017). During this same time period, nurse and anthropologist Madeleine Leininger, widely recognized as the founder of the field, began developing a concept she defined as "a comparative study and analysis of different cultures and subcultures in the world with respect to their caring behaviors, values, and beliefs about health, illness, and death" (Alligood, 2014; The Madeleine M. Leininger Collection, 1953-1995). Leininger worked with Native American communities in the United States, observing the importance of cultural beliefs and practices in health care delivery. She established the first transcultural nursing program at the University of Colorado in 1974 to train nurses to provide culturally sensitive care to clients from diverse backgrounds (The Madeleine M. Leininger Collection, 1953-1995).

According to Leininger's model, transcultural nursing can be applied at all levels of health care institutions. With the ever-increasing multicultural population in the United States, nurses increasingly encounter clients from diverse cultural backgrounds. These clients may have different beliefs about health and illness, attitudes toward health care providers, and expectations for their care. Without an understanding of these cultural differences, nurses may struggle to provide effective care that meets the needs of their clients.

Cultural competence in health care has been shown to positively impact public health outcomes (Jongen et al., 2018). Cultural competence training can include a range of practices, such as understanding the central role of culture in lives and how it shapes behavior, respect, and acceptance of cultural differences, learning to effectively utilize culturally adapted and culturally specific practices, and continuous development of one's awareness of personal cultural influences. Gopalkrishnan (2019) discusses the importance of cultural competence in addressing the possible negative impacts on different cultural groups of **intercultural interactions**—interactions between individuals from different cultural backgrounds—such as discrimination and marginalization. The skills and frameworks to manage these issues are necessary to promote public health and address health disparities among diverse client populations (Gopalkrishnan, 2019). See [Culturally and Linguistically Responsive Nursing Care](#) for more information on this topic.

22.2 Cultural Models

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 22.2.1 Explain the purpose of transcultural nursing models.
- 22.2.2 Describe the transcultural nursing models of Leininger, Giger and Davidhizar, Purnell, and Campinha-Bacote.
- 22.2.3 Appraise the strengths and limitations of various transcultural nursing models.

Transcultural nursing models guide nurses' provision of culturally competent care. Culturally competent care is a set of congruent behaviors, attitudes, and policies that enable health care professionals to work effectively in cross-cultural situations. It requires not only knowledge of different cultures but also the ability to apply that knowledge effectively. These models are designed to address the unique cultural needs of individuals, families, and communities. Transcultural nursing models aim to integrate transcultural concepts, theories, and practices into nursing education, research, and clinical applications; to improve transcultural nursing knowledge; and to

incorporate this knowledge into sensitive and effective nursing care to meet clients' cultural needs.

Transcultural Nursing Models

Several transcultural nursing models are used in nursing practice, education, and research. They include the culture care theory, transcultural assessment model, model of cultural competence, and model for cultural competence. Transcultural nursing models generally share a common goal of providing culturally competent care to clients from diverse backgrounds. However, each model has its unique focus and approach to achieving this goal. Nurses can use these models to guide their practice and improve their ability to provide high-quality care to clients from diverse cultural backgrounds. This section introduces each of the four models and compares them.

Leininger's Culture Care Theory

Madeleine Leininger's theory of culture care diversity and universality, also known as the culture care theory (CCT), is a nursing theory that focuses on the importance of understanding and respecting cultural differences in health care. According to Leininger, nurses should not only be aware of different cultural practices but also incorporate them into their care plans in a way that is congruent with the client's cultural beliefs, values, and lifeways.

The central idea of this theory is that nurses must understand clients' values, beliefs, and norms to provide quality care ([Figure 22.2](#)). The theory states that culture shapes how people think and behave, as well as their attitudes toward health care providers. If nurses are unaware of these differences, they may make assumptions about their clients' needs or preferences based on their cultural backgrounds. The theory is based on the following five principles (McFarland & Wehbe-Alamah, 2019):

- Culture is a broad concept that encompasses multiple aspects of human life, including beliefs, values, and practices. Cultural care is a necessary and valuable part of nursing care.
- Care is the essence of nursing. It is an essential and vital part of nursing practice that involves cognitively based assistive, supportive, facilitative, or enabling acts or decisions that are mostly tailor-made to fit with an individual, group, or institution's cultural values, beliefs, and lifeways.
- Culturally congruent care is the goal of nursing. It aims to provide care consistent with the client's cultural beliefs, values, and practices.
- Culturally competent care is a process. It involves nursing care that is respectful of and responsive to the cultural beliefs, values, and practices of the client and their community.
- Cultural care preservation, accommodation, and/or repatterning are modes of nursing actions and decisions. These modes of care are used to provide culturally congruent care based on the cultural needs and expectations of the client and their community.

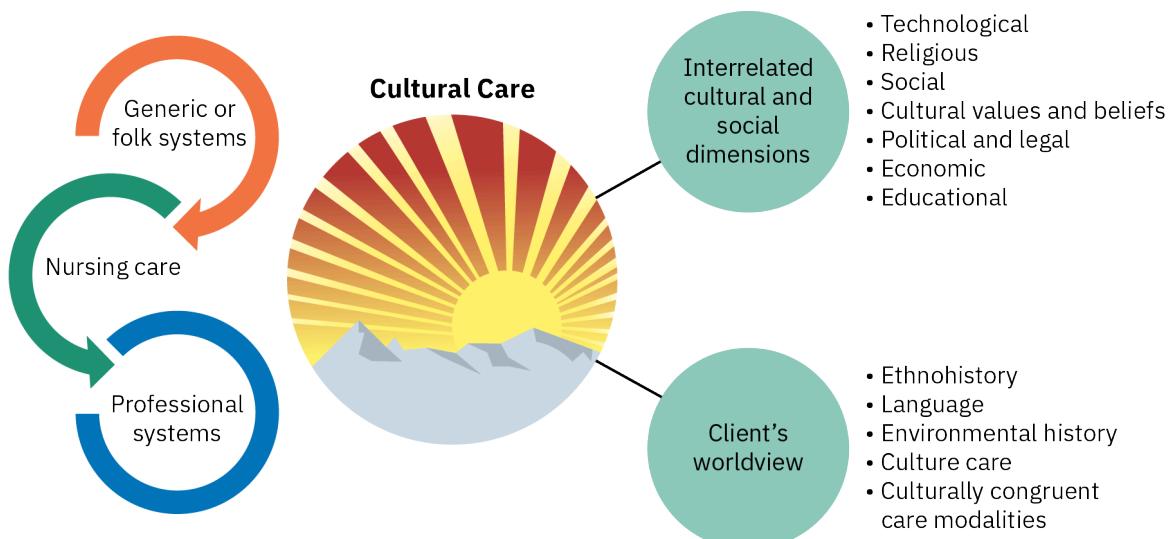

FIGURE 22.2 The sunrise model visually represents Leininger's culture care theory, emphasizing the importance of understanding and incorporating cultural factors in health care delivery. By using this model, nurses and other health care professionals can work toward delivering culturally appropriate and sensitive care that respects the unique needs and values of each individual and community. (See McFarland & Wehbe-Alamah, 2019; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The Leininger culture care theory and resulting sunrise model illustrate how culture is essential to nursing care and how providing culturally congruent care leads to better client outcomes. The sunrise model encompasses various dimensions essential to understanding culture care, including worldview, cultural and environmental context, and social structure factors. These dimensions help identify the values, beliefs, and practices that shape a particular culture's health care needs and preferences (McFarland & Wehbe-Alamah, 2019). Leininger believed that by recognizing and respecting these cultural factors, health care professionals can deliver culturally congruent care that meets the unique needs of individuals, families, and communities. The dimensions of the sunrise model include the following:

- Worldview is the cultural lens through which individuals perceive the world and their health. It includes spirituality, religion, and ethics, which significantly impact health care decisions and practices. Understanding a client's worldview allows nurses to provide care that aligns with their cultural and spiritual beliefs.
- Cultural and environmental context considers a cultural group's physical, social, economic, and political aspects, acknowledging the influence of the wider cultural and environmental factors on health and health care practices. By recognizing these contextual influences, nurses can adapt their care to better address the cultural nuances and challenges that clients face.
- Social structure factors reflect a culture's family roles, gender roles, and social hierarchies. These factors shape health care decision-making processes and expectations. Understanding the social structure factors allows nurses to provide care that considers the dynamics and hierarchies within a culture.

Culture care theory may be used in practice. For example, Nguyen et al. (2019) described how a culturally sensitive intervention was developed and implemented to improve the health outcomes of Vietnamese American women with type 2 diabetes. The intervention was developed based on the principles of Leininger's Culture Care Theory and included cultural care accommodation and negotiation. **Cultural care accommodation** was used to adapt the intervention to the cultural beliefs and practices of Vietnamese American women. For example, the intervention included a nutrition education component incorporating traditional Vietnamese foods and recipes. The intervention also included group exercise sessions held in a community center, a familiar and comfortable environment for the women. **Cultural care negotiation** addressed cultural conflicts and facilitated communication between the health care providers and the Vietnamese American women. For example, the health care providers worked with the women to develop a shared understanding of the importance of blood sugar control and the benefits of taking medication. The providers also discussed the potential side effects of medication and worked with the women to find a medication regimen that was acceptable to them.

The study found that the culturally sensitive intervention led to improvements in the participants' health outcomes, including better blood sugar control and improved quality of life. The authors suggest that using Leininger's culture care theory can help nurses and other health care providers develop culturally sensitive interventions that improve the health outcomes of diverse client populations (Nguyen et al., 2019).

Giger and Davidhizar Transcultural Assessment Model

In 1988 Giger and Davidhizar developed the transcultural assessment model, introduced in [Cultural Influences on Health Beliefs and Practices](#), to address the need for nursing students to provide care for clients from diverse cultural backgrounds. This model is designed to help health care providers identify and understand cultural differences in clients and to provide culturally competent care. According to this model, every culture shares six dimensions: communication, space, social organization, time, environmental control, and biological variation ([Figure 22.3](#)) (Giger & Davidhizar, 2002).

Communication: This dimension acknowledges that communication patterns and language differ among cultures and that health care professionals should be aware of these differences to provide culturally competent care.

Space: This dimension refers to the physical and personal space individuals require in different cultures. For instance, some cultures prefer to have more physical space between themselves and others, while others prefer to be in closer proximity to others. Understanding a client's space expectations can help health care providers create a comfortable care environment, which is crucial for building trust, rapport, and communication with the client. Additionally, space expectations can influence how clients respond to treatments or procedures; for example, some clients may feel more comfortable if a family member is present during a medical examination, while others may feel uncomfortable with the same arrangement.

Social Organization: This dimension is the way a culture structures itself around the family group and/or community, including the way communication, decision making, and role distribution occur within and among groups.

Time: This dimension is “a cultural specific orientation to the past, present, and future.” Inquiries about the perception of time can help health care providers understand how clients view the timing of events, the importance of punctuality, and the value of time concerning health and illness.

Environmental Control: This dimension is defined as the perception of an individual’s ability to control nature and the environment, including the use of natural resources, cultural sanctions, and technology.

Biological Variation: This dimension is defined as the factors such as race, body structure, genetic variations, nutritional preferences, and psychological characteristics that need to be considered when assessing a client’s cultural foundation to avoid stereotypes and discrimination.

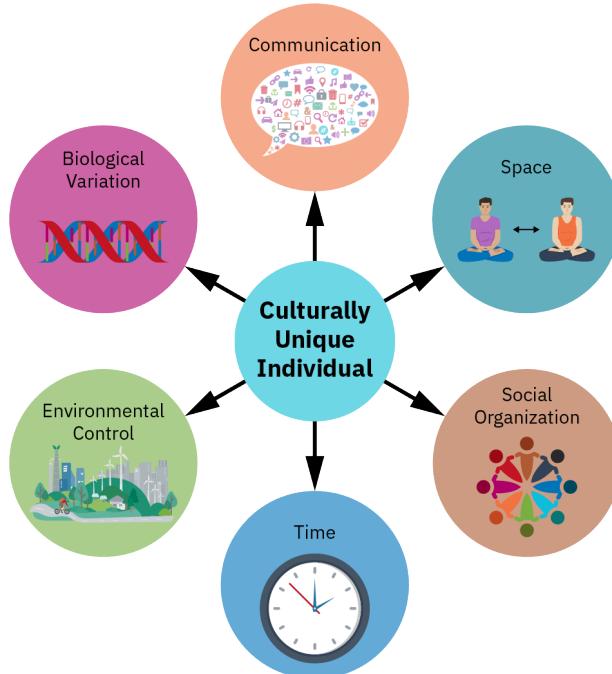

FIGURE 22.3 In the Giger and Davidhizar transcultural assessment model, six cultural dimensions provide a framework for client assessment and from which culturally sensitive care can be designed. (See Giger & Davidhizar, 2002; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

One strength of the Giger and Davidhizar transcultural assessment model is its holistic approach to cultural assessment (Albougami et al., 2016). The model looks at multiple dimensions of culture and how they interact with health and illness in order to provide nurses with a comprehensive understanding of clients’ experiences. However, the model has its limitations. Some critics argue that the model does not consider the diversity within cultures and assumes that all individuals from a particular culture will have the same beliefs or practices. For instance, if a nurse assumes that all people who identify as Hispanic have the same culture, they may make incorrect assumptions about an individual client, which may lead to cultural misunderstandings that affect the client’s care.

Additionally, the model may not be as useful for clients from cultures not well-represented in the model’s dimensions (Albougami et al., 2016). Let’s say that a nurse is caring for a client from a small, remote tribe in Africa. The tribe has unique cultural beliefs and practices that are not well-represented in the Giger and Davidhizar Transcultural Assessment Model’s dimensions. The nurse may struggle to understand the client’s cultural needs and be unable to provide culturally sensitive care using the model alone. The tribe may have specific beliefs around illness and healing that are not captured in the transcultural assessment model’s dimensions. The nurse may not be aware of these beliefs and may not be able to provide care that aligns with the client’s cultural practices. This can lead to a breakdown in trust between the client and the nurse and may result in the client receiving suboptimal care. Nurses should be aware of the limitations when using the model to provide culturally sensitive care. [Table 22.1](#) provides a case example using the Giger and Davidhizar transcultural assessment model.

In a diverse community health setting, Lou, a nurse, provides care for 70-year-old Mrs. Sato, who recently emigrated to the United States from Japan. Mrs. Sato has been experiencing symptoms of depression and anxiety since her arrival. Lou recognizes the importance of applying transcultural nursing principles and utilizes the Giger and Davidhizar transcultural assessment model to understand and address Mrs. Sato's unique needs.

Step 1: Gathering Data

Lou creates a safe and nonjudgmental environment for Mrs. Sato to share her experiences.

Mrs. Sato's cultural background: Japanese

Length of time living in the United States: 6 months

Primary language spoken: Japanese

Perceived support systems: Limited social connections in the new community

Physical health conditions: No significant medical issues reported

Previous experiences with the health care system: Limited exposure to Western medicine

Step 2: Assessing Six Cultural Phenomena

1. Communication	Mrs. Sato relies on her son to communicate in English, which may hinder effective communication with health care providers.
2. Space	Mrs. Sato values personal space and may feel uncomfortable with certain physical examinations or procedures.
3. Social Organization	Mrs. Sato has limited social support in the new community, which may contribute to her feelings of isolation and depression.
4. Time	Mrs. Sato may have different perceptions of time, which may affect her adherence to appointment schedules or medication regimens.
5. Environmental Control	Mrs. Sato may have different beliefs regarding control over her health decisions, which could influence her level of engagement in care.
6. Biologic Variations	Mrs. Sato's genetic and physiological makeup may differ from those of individuals from other cultures, impacting her response to treatment and medications.

Step 3: Analyzing the Data

The nurse develops an understanding of the potential influences of cultural factors on Mrs. Sato's mental health and overall well-being.

Step 4: Planning and Implementing Culturally-Sensitive Care

1. Communication	Lou arranges for a qualified interpreter fluent in Japanese to ensure accurate communication during health care visits.
2. Space	Lou explains the physical examinations and procedures in a culturally sensitive manner, allowing Mrs. Sato to express any discomfort or concerns.
3. Social Organization	Lou connects Mrs. Sato with community resources, such as local cultural organizations or support groups, to foster social connections and reduce feelings of isolation.
4. Time	Lou discusses appointment timings with Mrs. Sato, taking into consideration her cultural understanding of time to enhance adherence and punctuality.
5. Environmental Control	Lou involves Mrs. Sato in her care decisions, respecting her cultural views on health care and encouraging her to take an active role in managing her health.
6. Biologic Variations	Lou collaborates with the health care team to assess Mrs. Sato's genetic variations that may impact medication response to personalize her treatment plan.

TABLE 22.1 Case Review Using Giger-Davidhizar Transcultural Assessment Model (See Giger & Davidhizar, 2002.)

Purnell Model for Cultural Competence

The Purnell model for cultural competence is based on the belief that culture affects every aspect of human life, including health and illness (Purnell, 2002). The model offers a framework for health care providers to develop cultural competence and improve client outcomes. [Figure 22.4](#) illustrates the model, and [Table 22.2](#) presents a client example incorporating the 12 domains of the model.

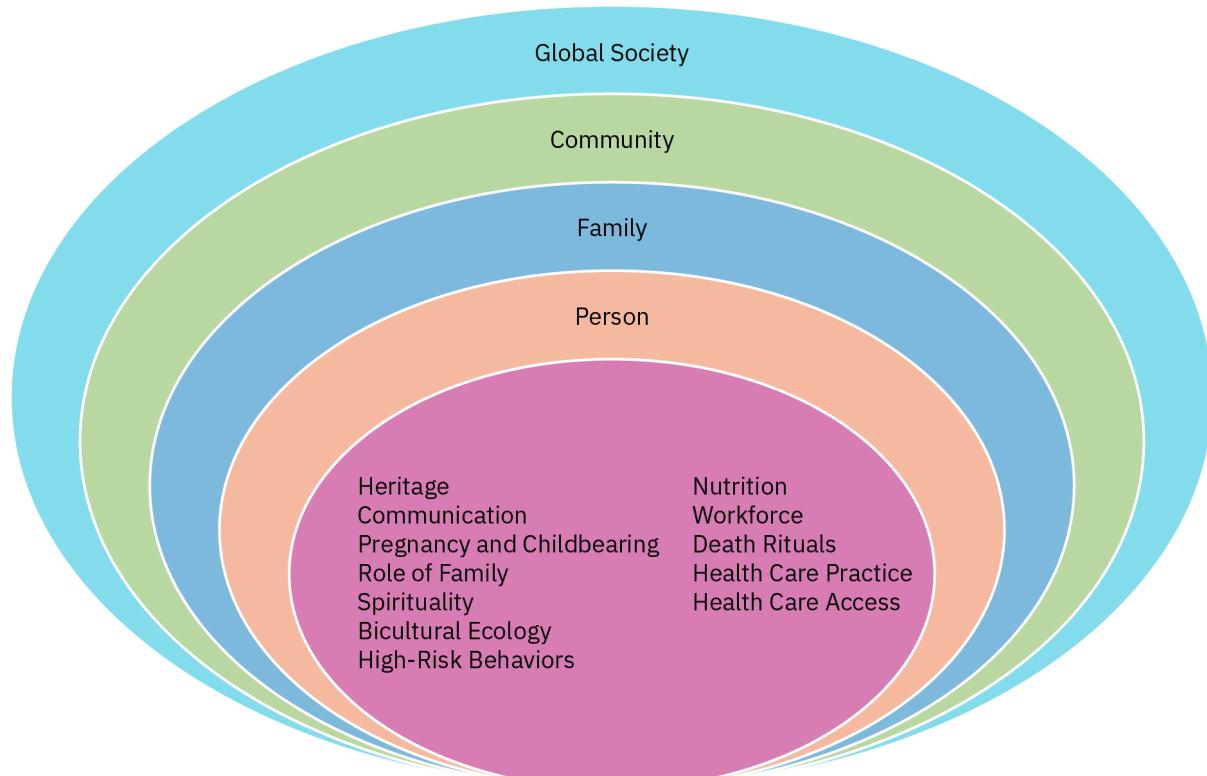

FIGURE 22.4 The Purnell model for cultural competence consists of 12 domains that provide a comprehensive framework for understanding and promotion cultural competence in health care. (See Purnell, 2018; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Domain	Name	Description	Example: Mr. Rodriguez, a 45-year-old male seeking health care in a community clinic
1	Overview and heritage	This domain includes the client's ethnic and racial background, as well as their country of origin and primary language.	<ul style="list-style-type: none"> • Ethnicity and nationality: Mexican • Length of time living in the United States: 6 months • Primary language spoken: Spanish • Cultural beliefs and practices regarding health and illness: The importance of family support and the use of traditional herbal remedies • Dietary preferences and restrictions: Traditional Mexican cuisine and possible dietary restrictions due to diabetes • Spiritual beliefs and practices: Catholicism and religious rituals practiced within the family
2	Communication	This domain includes the client's language proficiency, nonverbal communication, and other cultural communication patterns.	<ul style="list-style-type: none"> • The nurse ensures bilingual services or language interpreters are available during health care encounters to enhance communication between Mr. Rodriguez and the health care team.
3	Family roles and organization	This domain includes the client's family structure, gender roles, and family values.	<ul style="list-style-type: none"> • The nurse involves Mr. Rodriguez's family in his diabetes management education and provides resources for family members to understand his condition and contribute to his care.

TABLE 22.2 Purnell Model for Cultural Competence Domains of Culture (See Purnell, 2018.)

Domain	Name	Description	Example: Mr. Rodriguez, a 45-year-old male seeking health care in a community clinic
4	Workforce issues	This domain includes the client's employment status, occupation, and education level.	<ul style="list-style-type: none"> The nurse acknowledges any potential language barriers Mr. Rodriguez may face in finding employment or accessing health care services.
5	Biocultural ecology	This domain includes the client's physical and environmental factors that affect their health, such as diet and exercise habits.	<ul style="list-style-type: none"> The nurse understands the influence of traditional Mexican cuisine, home remedies, and cultural beliefs on Mr. Rodriguez's overall health.
6	High-risk behaviors	This domain includes the client's behaviors, such as smoking or substance use, that may lead to negative health outcomes.	<ul style="list-style-type: none"> The nurse addresses potential high-risk behaviors, such as traditional remedies conflicting with prescribed medications, and educates Mr. Rodriguez about potential risks.
7	Nutrition	This domain includes the client's dietary habits, food preferences, and beliefs about food and health.	<ul style="list-style-type: none"> The nurse assesses Mr. Rodriguez's understanding of nutrition, providing culturally appropriate recommendations to accommodate traditional Mexican cuisine while managing his diabetes. The nurse works with a registered dietitian to tailor a diabetes meal plan incorporating traditional Mexican cuisine, making necessary adjustments to ensure adherence to dietary restrictions and optimal glycemic control.
8	Pregnancy and childbearing	This domain includes the client's beliefs and practices related to pregnancy and childbirth.	<ul style="list-style-type: none"> Although not applicable in this case, the nurse is aware of the cultural practices surrounding pregnancy and childbirth in Mexican culture.
9	Death rituals	This domain includes the client's beliefs and practices related to death and dying.	<ul style="list-style-type: none"> Although not applicable in this case, the nurse is aware of the cultural practices surrounding death rituals in Mexican culture.
10	Spirituality	This domain includes the client's beliefs and practices related to spirituality and religion.	<ul style="list-style-type: none"> The nurse demonstrates respect for Mr. Rodriguez's religious practices and incorporates any relevant rituals or spiritual support in his care.

TABLE 22.2 Purnell Model for Cultural Competence Domains of Culture (See Purnell, 2018.)

Domain	Name	Description	Example: Mr. Rodriguez, a 45-year-old male seeking health care in a community clinic
11	Health care practices	This domain includes the client's beliefs and practices related to health care, including beliefs about illness and treatment.	<ul style="list-style-type: none"> The nurse explores traditional herbal remedies, discusses their potential interactions with prescribed medications, and collaborates with Mr. Rodriguez to find a compromise that aligns with his beliefs while ensuring safety and efficacy.
12	Health care access	This domain includes the client's access to health care services, including insurance coverage and transportation.	<ul style="list-style-type: none"> The nurse learns from Mr. Rodriguez's experiences, seeks resources, collaborates with interdisciplinary teams (including care management), and incorporates cultural humility into their practice.

TABLE 22.2 Purnell Model for Cultural Competence Domains of Culture (See Purnell, 2018.)

Community health nurses using the Purnell model would consider factors such as communication styles, family dynamics, health care practices, and dietary preferences within specific cultural groups. For instance, when working with a Hispanic community, a community health nurse using the Purnell model would recognize the importance of language and might utilize interpreters to facilitate effective communication. The nurse would also understand the significance of family involvement in health care decisions and involve family members in the care process. Additionally, the nurse would consider traditional Hispanic food preferences and cultural beliefs around nutrition, incorporating culturally appropriate dietary advice.

Strengths of the Purnell model include its comprehensive nature and emphasis on understanding each client's unique cultural background. It provides a structured framework for nurses to assess, plan, and implement care tailored to each client's cultural needs. The model has also been revised and updated to reflect changes in health care practices and incorporate new research findings.

Limitations of the Purnell model are its complexity and that it may be too time-consuming to apply in a busy clinical setting. This is because the model involves a detailed assessment of all 12 domains of an individual's culture, including beliefs, values, traditions, and practices. The model also requires nurses and other health care providers to be knowledgeable about a wide range of cultures. Additionally, the model focuses primarily on individual clients and may not adequately address the cultural needs of families or communities.

Campinha-Bacote's Process of Cultural Competence in the Delivery of Healthcare Services

Campinha-Bacote's model of cultural competence in the delivery of healthcare services is a framework that helps health care providers become more culturally competent in their care delivery. This model is based on five constructs: cultural awareness, cultural knowledge, cultural skill, cultural encounter, and cultural desire (Campinha-Bacote, 2018). Within these constructs, cultural competence and cultural humility are not alternative approaches. Instead, they work together to define a process that not only is a lifelong reflective process but also places importance on cultural encounters and learning to increase cultural competence.

- **Cultural awareness** is the first construct and refers to nurses' self-awareness of their own cultural values and beliefs.
- **Cultural knowledge** refers to nurses' understanding of different cultures and their values, beliefs, and practices.
- **Cultural skill** refers to nurses' ability to adapt their skills to meet the needs of clients from different cultures.
- **Cultural encounters** are nurses' direct engagement with clients from different cultures.
- **Cultural desire** refers to nurses' motivation to become culturally competent.
- **Cultural competemility** refers to the synergistic relationship between cultural competence and cultural humility.

One of the strengths of this model is its emphasis on the importance of the nurse's self-awareness and motivation to become culturally competent. It recognizes that cultural competence is not just about acquiring knowledge or skills but also about a nurse's commitment to providing culturally sensitive care. Both are critical for providing culturally

sensitive care to clients from diverse backgrounds.

There are also some limitations to Campinha-Bacote's model of cultural competence. Some critics argue that this model does not clearly define cultural competence and does not offer specific strategies for health care providers to become more culturally competent (Albougami et al., 2016). Additionally, this model may not be as useful for clients from cultures not well-represented in the model's constructs. For example, consider a nurse who is working with a client from a culture that places a high value on community and collective decision making. While the Campinha-Bacote model includes the construct of cultural encounters, which emphasizes the importance of interacting with individuals from diverse cultural backgrounds, it may not fully prepare the nurse to understand and respect the client's cultural values around decision making. In this case, the nurse may need additional resources or training to address the client's cultural background and values. This could involve consulting with a cultural expert or community leader or seeking out literature or other resources that provide insights into the client's culture. [Table 22.3](#) presents a client example incorporating the constructs of this model.

Fifty-five-year-old Mr. Ivan Petrov, who recently emigrated to the United States from Russia, presents to a community health clinic with symptoms of depression. His primary language is Russian. The nurse caring for Mr. Petrov speaks Russian and has completed a Qualified Bilingual Staff (QBS) Assessment for general communication; additional assessment would be needed for medical interpretation.

Cultural Awareness	The nurse understands that Mr. Petrov's recent emigration from Russia might influence his perceptions, health beliefs, and attitudes toward health care. The nurse acknowledges the potential challenges this client might face as an immigrant, such as language barriers and cultural adjustment.
Cultural Knowledge	The nurse researches Russian cultural values, health beliefs, and customs to gain insight into Mr. Petrov's cultural background. The nurse learns about the importance of family, the potential stigma associated with mental health in Russian culture, and the role of traditional healing practices.
Cultural Skill	During the interaction, the nurse greets Mr. Petrov in Russian and uses culturally appropriate greetings, such as "Здравствуйте" (Hello). They introduce themselves by their name and role, explaining their purpose and the reason for their inquiry. The nurse ensures confidentiality and builds a rapport with Mr. Petrov to foster trust and comfort.
Cultural Encounters	The nurse engages in a therapeutic conversation with Mr. Petrov to understand his symptoms, concerns, and cultural background. The nurse asks open-ended questions to explore his experiences, considering any cultural factors that may impact his mental health.
Cultural Desire	The nurse demonstrates genuine interest in and respect for Mr. Petrov's cultural background and experiences by expressing empathy and compassion, showing a desire to provide client-centered care that respects his autonomy and values.
Cultural Competence	The nurse collaborates with language interpreters or utilizes professional translation services to ensure effective communication and reduce language barriers. With Mr. Petrov's consent, the nurse involves the client's family in decision making and care planning, understanding the importance of family support in his health care journey.

TABLE 22.3 Campinha-Bacote's Model of Process of Cultural Competence in the Delivery of Healthcare Services (See Campinha-Bacote, 2002.)

Strengths and Limitations of Transcultural Nursing Models

One strength of transcultural nursing models is their emphasis on culturally sensitive care. Culturally sensitive care involves respecting and incorporating clients' cultural beliefs, practices, and values into health care delivery (Purnell, 2013). This approach can help health care providers better understand and address the unique health needs and concerns of clients from diverse backgrounds. Another strength of these models is their focus on trust-building and communication. Trust is a critical component of effective health care delivery, and it is often built through good communication and mutual respect between health care providers, including nurses, and clients. Campinha-Bacote (2002) emphasizes the importance of establishing trust and rapport with clients to facilitate effective communication and promote positive health outcomes. Collaborative care is another essential component of transcultural nursing models. It involves working with clients and their families to develop treatment plans that

align with their cultural beliefs and values. Leininger's sunrise model of transcultural nursing emphasizes the importance of collaboration between clients, families, and health care providers to ensure that care is culturally congruent.

However, despite these strengths, transcultural nursing models also have several limitations. For example, **ethnocentrism**, or the tendency to view one's culture as the norm and superior to others, can lead nurses to lack understanding and respect for cultural differences. Nurses must be aware of their biases and work to overcome them to provide culturally sensitive care. **Cultural imposition**, or imposing one's cultural beliefs and values on others, is another danger of transcultural nursing models, as it can result in cultural conflicts and misunderstandings. Nurses must be careful not to impose their own cultural views on clients and must work to understand and respect clients' cultural beliefs and practices. **Cultural essentialism** can be a limitation of transcultural nursing models. This is the assumption that all members of a particular cultural group share a set of essential traits that define their identity. Nurses must be careful not to make assumptions about clients based on their cultural background and must work to understand and respect the unique needs and experiences of each client. Finally, clients may experience **culture shock**, another potential limitation of transcultural nursing models. Culture shock is the experience of personal disorientation when confronted with an unfamiliar way of life. Nurses must be aware of this phenomenon and work to understand and address the unique needs of clients experiencing culture shock. [Table 22.4](#) compares the four transcultural models just discussed.

Theory	Theory of Culture Care Diversity and Universality	Transcultural Assessment Model	Model for Cultural Competence	Process of Cultural Competence
Theorist	Leininger	Giger and Davidhizar	Purnell	Campinha-Bacote
Emphasis	The importance of understanding and respecting cultural differences in health care	The assessment of cultural characteristics and their impact on health and illness	The belief that culture affects every aspect of human life, including health and illness	The importance of cultural competence in nursing practice
Main Tenets	Cultural care is essential to nursing; providing culturally congruent care leads to better client outcomes.	Includes six cultural phenomena: communication, space, social organization, time, environmental control, and biological variations	Includes 12 domains of culture: communication, family roles and organization, workforce issues, health beliefs and practices, and biocultural ecology	Includes five constructs: cultural awareness, cultural knowledge, cultural skill, cultural encounters, and cultural desire
Purpose	To provide a framework for the delivery of culturally congruent care	To help nurses assess cultural factors that may affect client care	To help nurses develop the knowledge and skills needed to provide culturally competent care to clients from diverse backgrounds	To help nurses develop the knowledge, skills, and attitudes needed to provide culturally competent care

TABLE 22.4 Comparisons of Transcultural Nursing Models

CONVERSATIONS ABOUT CULTURE

Health Care Outlook: Exercising Cultural Sensitivity / Carmen Alvarez

[Access multimedia content \(<https://openstax.org/books/population-health/pages/22-2-cultural-models>\)](https://openstax.org/books/population-health/pages/22-2-cultural-models)

In this short video, Assistant Professor of Nursing Carmen Alvarez describes why nurses should spend time asking clients questions to understand their needs and adapt their care.

Watch the video, and then respond to the following questions.

1. Why is the first step in providing culturally sensitive care understanding your own limitations?
2. What cultural assumption did Carmen make when caring for a client?
3. Think of a time when you made a cultural assumption about another person. How might you prevent a similar situation from occurring in the future?

22.3 Cultural Assessment

LEARNING OUTCOMES

By the end of this section, you should be able to:

- 22.3.1 Assess how different cultures, customs, and social and health care practices impact nursing care to enhance cultural sensitivity and promote delivery of compassionate care.
- 22.3.2 Perform a cultural assessment to promote cultural sensitivity and humility in practice.
- 22.3.3 Describe strategies to incorporate traditions and personal views in the plan of care to demonstrate empathy for the individual's life experience.

As discussed in [Cultural Influences on Health Beliefs and Practices](#), diversity refers to the differences among clients in terms of their culture, race, ethnicity, religion, language, customs, beliefs, and other factors that shape their health care needs and preferences. Culturally competent care involves acknowledging diversity, respecting and valuing it, and providing care sensitive to each client's needs and preferences.

Cultural impacts on nursing care include differences in health care outcomes for racial and ethnic groups, which can vary significantly from one region to another and may result from structural inequities or cultural preferences in care. Other factors influencing cultural competence in nursing care include race, socioeconomic status, health literacy, and language barriers. Additionally, increasing the diversity of the nursing workforce can improve client care, as it helps ensure that clients receive care from health care providers who understand their cultural backgrounds.

Cultural Nursing Assessment

A **cultural nursing assessment** systematically identifies the beliefs, values, meanings, and behaviors of an individual client or population while considering their history, life experiences, and social and physical environments. In a brief cultural assessment, the nurse should ask about ethnic background, religious preference, family patterns, food preferences, eating patterns, and health practices (Narayan & Mallinson, 2022). A cultural assessment can provide the information needed for a nurse to engage in effective **cultural bridging**, in which the nurse recognizes the elements of care that may be different from what a client is accustomed to and respectfully explains what the client can expect and why. A respectful exchange of information benefits both the nurse and the client and leads to better health outcomes.

Community health nurses are crucial in delivering culturally appropriate care to diverse populations. It is essential for these nurses to actively engage in efforts to provide care that respects the unique needs of individuals from different backgrounds. By involving clients in their care and empowering them to participate in decisions regarding their health-related goals, plans, and interventions, nurses help to ensure improvement in both client compliance and outcomes. As a community health nurse, embracing a continuous learning mindset is vital. It is important to have a commitment to ongoing personal and professional growth while also seeking to deepen the understanding of others. By striving to provide the best possible care and continuously expanding knowledge, community health nurses can ensure they contribute effectively to the well-being of their diverse client populations.

CONVERSATIONS ABOUT CULTURE

Cultural Competency for Providers

[Access multimedia content \(<https://openstax.org/books/population-health/pages/22-3-cultural-assessment>\)](https://openstax.org/books/population-health/pages/22-3-cultural-assessment)

This video presents a case study about Najma, a young Somali woman who was resettled by the United Nations in Lewiston, Maine, and soon discovers she is pregnant. The case follows Najma as she navigates the unfamiliar U.S. health care system.

Watch the video, and then respond to the following questions.

1. How can health care workers seek to understand cultural differences, especially in refugee populations?
2. Explain the concept of cultural bridging and identify techniques that can help.

Culturally Sensitive Environment

Nurses perform cultural assessments by first establishing a culturally sensitive environment and then incorporating a cultural assessment when caring for all clients. A **culturally sensitive environment** is a health care setting that is respectful and responsive to clients' and their families' cultural backgrounds, beliefs, and values. It is an environment that recognizes and values the diversity of clients and strives to provide care free from cultural bias or discrimination.

A culturally sensitive physical environment in health care incorporates various characteristics to accommodate clients' diverse cultural needs. This includes displaying décor, symbols, and artwork that reflect the diversity of the client population, providing multilingual signage and communication to overcome language barriers, ensuring client privacy and modesty, and promoting a knowledgeable and diverse staff. This environment promotes open communication between health care providers and clients. It encourages clients to express their beliefs and concerns about their health and health care. It also involves providing health care services that are appropriate and effective for clients from different cultural backgrounds. This includes being aware of cultural differences in areas such as diet, lifestyle, and religious practices and adapting care to meet each client's individual needs.

Nurses can create a culturally sensitive environment by actively promoting cultural competence, learning about and understanding the cultural backgrounds of their clients, and developing the skills necessary to provide respectful and responsive care to meet their needs. Nurses may attend cultural competence training programs, use interpreters when necessary, and create informational materials that are culturally appropriate for clients from different backgrounds. Overall, a culturally sensitive environment is essential for providing high-quality health care that is accessible and respectful to clients from diverse cultural backgrounds.

Once the nurse has established a culturally sensitive environment, they must learn about the meaning of the illness in terms of the client's unique culture. This can be done by asking open-ended questions about the client's background, beliefs, and values. For example, some questions to ask during a cultural assessment include "What do you think has caused your problem?" and "Why do you think it started when it did?" Effective verbal and nonverbal communication is also essential for building trust and promoting respect with the client.

Before the assessment, the nurse should know the key topics to address, how to address them without offending the client and family, and whether an interpreter is necessary.

Performing Cultural Nursing Assessment

A culturally competent nursing assessment is a process of gathering information about a client's cultural background, beliefs, and practices to provide culturally sensitive care. The assessment aims to identify cultural factors that may influence the client's health care needs and decisions and to develop a care plan that is respectful and responsive to the client's cultural beliefs and practices.

The following are key components of a culturally competent nursing assessment:

1. Gathering cultural information: The nurse should collect information about the client's cultural background, including their beliefs, values, and practices related to health and illness. This includes asking the client about their language preferences, religious practices, dietary restrictions, and other cultural practices.
2. Awareness and knowledge: The nurse should have foundational knowledge about the community and diversity within the community. For example, nurses should be familiar with concepts related to sexual orientation and gender identities, including common terminology.
3. Assessing health literacy: The nurse should assess the client's health literacy, which is the ability to understand and use health information to make informed decisions. The nurse should use plain language and culturally appropriate materials to assess the client's understanding of their health condition and treatment plan.
4. Identifying cultural barriers: The nurse should identify any cultural barriers that may affect the client's health care access or outcomes, such as language barriers, limited access to health care services, or cultural beliefs

that conflict with Western medicine. Understanding why clients might delay care due to the barriers they encounter when accessing safe health care can help nurses plan for a client's ongoing care.

5. Assessing cultural competence: The nurse should assess their own cultural competence, including their knowledge, attitudes, and skills related to providing culturally sensitive care. This includes recognizing any biases or stereotypes they may hold and addressing them appropriately.
6. Developing a culturally sensitive care plan: Based on the information gathered during the assessment, the nurse should develop a care plan that is respectful and responsive to the client's cultural beliefs and practices. Additionally, the nurse should use inclusive and gender-neutral language and respect names and pronouns. Treatment plans may need to be adapted to accommodate cultural practices, using interpreters or culturally appropriate resources or involving family members in the care plan.

During the assessment, the nurse should be aware of the environment. They should look around and also assess verbal and nonverbal communications.

The brief cultural assessment helps determine the need for an in-depth cultural assessment, which can be conducted throughout the nurse-client relationship as trust builds. The longer Culturological Assessment, a term coined by Leininger (2002), also known as the Cultural Assessment, includes additional questions in major data categories covering a wide range of topics. The box below provides sample questions nurses may use to begin a brief cultural assessment.

CONVERSATION STARTERS FOR A BRIEF CULTURAL ASSESSMENT

“Forgive me...I was wondering if I could ask a few questions...”

“At times like this, many people draw on their religious/spiritual beliefs to help them...”

- Is there anything the nurses can do to help you find the spiritual strength you need at this time?
- Are there spiritual practices that we can facilitate for you? Is there a religious leader/healer who you might find helpful?
- The health care team caring for you wants to be polite and respectful to you and your family...
- How would you like to be addressed by our staff?
- What pronouns do you prefer?
- Are there certain cultural courtesies we should practice when we come to visit you?
- Are there things we might do that you would find offensive?
- Could you please let us know if anything we do seems rude or offensive so we can fix it?

“Everyone has cultural beliefs and customs that they find help them to heal...”

- Are there special beliefs or customs you would like to keep related to this health problem?
- Are there special herbs/foods/treatments you have found helpful?
- Are there healers from your community who might also be able to help you?
- How does your family think this illness should be treated?
- What do you think about this treatment?
- What are the characteristics of a good health care provider (e.g., nurse, doctor, social worker, etc.)?

(Adapted from Narayan, 2003.)

CONVERSATIONS ABOUT CULTURE

Using Inclusive Language When Taking a Patient History

[Access multimedia content \(<https://openstax.org/books/population-health/pages/22-3-cultural-assessment>\)](https://openstax.org/books/population-health/pages/22-3-cultural-assessment)
This video explores the necessity of using inclusive language when taking a client history.

Watch the video, and then respond to the following questions.

1. Why is it important to standardize language in assessments and use them with all clients; for example,

- asking all clients for their preferred pronouns?
2. Explain the concept of identity versus biology and how you might use inclusive language to ask assessment questions.

Incorporating Culture into the Plan of Care

Incorporating traditions and personal views in the care plan is essential to demonstrate empathy and respect for the client's life experience. **Empathy**, the ability to understand and share the feelings, perspectives, and experiences of others, is an important part of providing culturally responsive care. Nurses can establish trust and rapport by consistently demonstrating empathy and respect. Nurses should actively listen to clients, demonstrating genuine interest and using appropriate nonverbal cues such as nodding, eye contact, and facial expressions to show empathy ([Figure 22.5](#)). Nurses should acknowledge and validate clients' emotions and experiences, ensuring they feel heard and understood.

FIGURE 22.5 A nurse shows empathy by actively listening and using nonverbal cues, such as eye contact, to build trust and rapport with the client. (credit: "University of California, Irvine" by Paul R. Kennedy/Flickr, Public Domain)

Here are some strategies that nurses can use to incorporate these elements in their care plan:

1. Ask the client about their cultural traditions and preferences: By doing this, the nurse can gain insight into the client's values and beliefs and incorporate these elements into the plan of care in a way that is respectful and meaningful to the client.
2. Use interpreters: If the client and the nurse do not speak the same language, using an interpreter can help the nurse understand the client's beliefs and preferences. This can help the nurse incorporate these elements into the plan of care.
3. Involve family members (when culturally appropriate): Family members can play an essential role in incorporating traditions and personal views into the care plan. Involving family members in discussions about the plan of care can help the nurse understand the client's cultural beliefs and preferences.
4. Be flexible: Being willing to adapt the plan of care to meet the client's needs and preferences is essential. This can involve adjusting the timing of treatments or medications to accommodate the client's religious practices or dietary restrictions.
5. Use culturally appropriate resources: Educational materials and videos can help the nurse provide respectful and culturally sensitive care.

Incorporating traditions and personal views into the care plan requires nurses to be open-minded, flexible, and

willing to learn about the client's cultural background and beliefs. By doing so, they can provide care that is respectful, empathetic, and meaningful to the client.

CASE REFLECTION

Incorporating Culture in a Refugee Vaccination Program

Read the scenario, and then respond to the questions that follow.

A public health nurse working with a community of refugees is tasked with implementing a vaccination program to prevent the spread of a highly contagious disease in the community. The nurse is aware that many community members come from cultures where vaccinations are not widely accepted or are met with suspicion and wants to ensure that the program is culturally sensitive and effectively reaches and educates the community about the importance and safety of vaccines.

Public health nurses must consider the community's cultural beliefs and values surrounding vaccination to effectively reach and educate them. By conducting comprehensive cultural assessments and implementing appropriate strategies, the nurse can ensure that the program is culturally sensitive and meets the unique needs of the refugees.

1. Conducting Cultural Assessments

- Gather community information: Research and gather information about the cultural backgrounds of, languages spoken by, and beliefs of the members of the refugee community.
- Engage cultural brokers: Collaborate with cultural brokers or community leaders who can provide insights into the community's beliefs and assist in designing the vaccination program.
- Conduct interviews and focus groups: Conduct interviews and focus groups with community members to understand their perceptions, concerns, and experiences related to vaccination.

2. Developing Culturally Sensitive Strategies

- Understand cultural beliefs: Research and understand the cultural beliefs and values surrounding vaccination within the refugee community.
- Tailor educational materials: Develop culturally appropriate educational materials that acknowledge and address the specific concerns and beliefs of the community.
- Collaborate in decision making: Engage community members in the decision-making process, ensuring their opinions and preferences are considered in the development of the vaccination program.
- Ensure language accessibility: Provide interpreters and translated materials to overcome language barriers during the education and vaccination process.
- Provide culturally competent health care providers: Ensure that health care providers involved in the program are trained in cultural competence and demonstrate sensitivity and respect toward different cultural beliefs.

3. Promoting Community Engagement

- Establish trust and rapport: Build trust and rapport within the community by establishing relationships, respecting cultural practices, and showing empathy and understanding.
- Utilize community influencers: Collaborate with community influencers and leaders to raise awareness, address concerns, and promote vaccination within the refugee community.
- Conduct culturally tailored health-education sessions: Host culturally tailored health-education sessions that address the community's cultural beliefs and values surrounding vaccination, providing accurate and evidence-based information.
- Utilize culturally sensitive messaging: Develop messaging that resonates with the community, acknowledging their concerns and highlighting the importance of vaccination in the context of their cultural beliefs and values.

Implementing a culturally sensitive vaccination program for a community of refugees involves conducting cultural assessments, developing appropriate strategies, and promoting community engagement. By understanding and respecting the cultural beliefs and values of the community, public health nurses can effectively reach and educate
